CHAIRMAN OF CONFERENCE

Prof. Dr. Muhittin DOĞAN	Gaziantep University, Turkey

ORGANIZING COMMITTEE

Prof. Dr. Ali Tuncay ÖZYILMAZ	Hatay Mustafa Kemal University, Türkiye
Prof. Dr. Ayten NAMLI	Ankara University, Türkiye
Prof. Dr. Erol ATAY	Hatay Mustafa Kemal University, Türkiye
Prof. Dr. Gülşen ALTUĞ	Istanbul University, Türkiye
Prof. Dr. Hasan KÜÇÜKBAY	İnönü University, Türkiye
Prof. Dr. Hüseyin ZENGİN	Gaziantep University, Türkiye
Prof. Dr. Maria DAGLIA	University of Naples Federico II, Italy
Prof. Dr. Miloudi HLAIBI	University of Hassan II Casablanca, Morocco
Prof. Dr. Mustafa DJAMGOZ	Imperial College London, United Kingdom
Prof. Dr. Nabeel AHMAD	Dev Bhoomi Uttarakhand University, India
Prof. Dr. Ravichandran RAMASAMY	New York University, USA
Prof. Dr. Serap DERMAN	Yildiz Technical University, Türkiye
Prof. Dr. Soumia KOUADRI MOUSTEFAI	Hassiba Benbouali University of Chlef, Algeria
Prof. Dr. Ümmühan ÖZDEMİR ÖZMEN	Gazi University, Türkiye
Prof. Dr. William A. COETZEE	New York University, USA
Prof. Dr. Zeliha SELAMOĞLU	Niğde Ömer Halisdemir University, Türkiye
Assoc. Prof. Dr. Alevcan KAPLAN	Batman University, Türkiye
Assoc. Prof. Dr. Barkat ULLAH	Islamia College Peshawar, Pakistan
Assoc. Prof. Dr. Demet DOĞAN	Gaziantep University, Türkiye
Assoc. Prof. Dr. Khassanov VADIM	S.Seifullin Kazakh Agro Technical Research University, Kazakhistan
Assoc. Prof. Dr. Musfata PEHLİVAN	Gaziantep University, Türkiye
Assoc. Prof. Dr. Mustafa SEVİNDİK	Osmaniye Korkut Ata University, Türkiye
Assoc. Prof. Dr. Rezarta SHKRELI	ALDENT University, Albania
Assoc. Prof. Dr. S.D. SARASWATHY	Bharathidasan University, India
Assoc. Prof. Dr. Serpil KILIÇ	Isparta University of Applied Sciences, Türkiye

INTERNATIONAL SCIENTIFIC COMMITTEE*

Prof. Dr. Adem ÖNAL	Gaziosmanpasa University, Türkiye
Prof. Dr. Adil M. ALLAHVERDİYEV	Yıldız Technical University, Türkiye
Prof. Dr. Adnan AYHANCI	Eskişehir Osmangazi University, Türkiye
Prof. Dr. Ahmed IMTIAJ	University of Rajshahi, Bangladesh
Prof. Dr. Ahmet AKSOY	Akdeniz University, Türkiye
Prof. Dr. Ahmet ASAN	Trakya University, Türkiye
Prof. Dr. Ahmet KARADAG	Bartın University, Türkiye
Prof. Dr. Aida SAHMUROVA	Okan University, Türkiye
Prof. Dr. Ali BİLGİLİ	Ankara University, Türkiye
Prof. Dr. Alime Ebru AYDIN	Hatay Mustafa Kemal University, Türkiye
Prof. Dr. Alpaslan DAYANGAÇ	Osmaniye Korkut Ata University, Türkiye
Prof. Dr. Arife Alev KARAGÖZLER	Aydın Adnan Menderes University, Türkiye
Prof. Dr. Atila YILDIZ	Ankara University, Türkiye
Prof. Dr. Aycan TOSUNOĞLU	Bursa Uludağ University, Türkiye
Prof. Dr. Aygül KÜÇÜKGÜLMEZ YANDIM	Cukurova University, Türkiye
Prof. Dr. Ayla BALABAN GUNDUZALP	Gazi University, Türkiye
Prof. Dr. Aysel GÜVEN	Başkent University, Türkiye
Prof. Dr. Ayşe Dilek ÖZŞAHİN KİREÇCİ	Bitlis Eren University, Türkiye
Prof. Dr. Ayşe Gül MUTLU	Mehmet Akif Ersoy University, Türkiye
Prof. Dr. Başak HANEDAN	Atatürk University, Türkiye
Prof. Dr. Belgin GÖZMEN SÖNMEZ	Mersin University, Türkiye
Prof. Dr. Belma ASLIM	Gazi University, Türkiye
Prof. Dr. Berrin DURAN	Eskisehir Osmangazi University, Türkiye
Prof. Dr. Bülent KAYA	Akdeniz University, Türkiye
Prof. Dr. Dilek DEMİREZEN YILMAZ	Erciyes University, Türkiye
Prof. Dr. Ebru AKTAN	Gazi University, Türkiye
Prof. Dr. Ebru Gül ASLAN	Süleyman Demirel University, Türkiye

FOREWORD

The *8th International Eurasian Conference on Biological and Chemical Sciences* (*EurasianBioChem 2025*) was successfully held on December 17-19, 2025 with participation from many countries.

The objective of *EurasianBioChem 2025* was to bring together leading academicians, researchers, scholars, and industrial professionals from all over the world to exchange and share their experiences and research findings in all aspects of biological and chemical sciences, as well as to discuss practical challenges and the solutions adopted. In this context, we were honored to welcome distinguished scientists, and our greatest appreciation goes to all participants whose valuable contributions made this conference a success. I would also like to thank the organizing committee and the scientific committee for providing such an intensive and high-quality scientific environment.

I believe that *EurasianBioChem 2025* has made significant contributions to all participants, and I look forward to seeing you at the *9th International Eurasian Conference on Biological and Chemical Sciences (EurasianBioChem 2026)*.

Prof. Dr. Muhittin DOĞAN

Chairman of *EurasianBioChem 2025*

Content

1. ORAL PRESENTATIONS **2**

1.1. ABSTRACTS **4**

Neuroinflammation in chronic urticaria: A bibliometric analysis of global research output 6

The influence of self-prepared foot care product on foot microbiome 7

Assessment of pregabalin misuse: A prospective and analytical study 8

Associations between disc displacement, degenerative changes, and inflammatory findings in TMJ: An MRI-based study 9

The effect of collagen supplementation on skin structure and signs of aging 10

Oleic acid nitrogen derivatives as antistatic additives 11

Ultrastructural analysis of the midgut epithelium of *Lithobius forfocatus* (Myriapoda, Chilopoda) exposed to different concentrations of nanostyrene 12

Assessing the impact of breakfast consumption on cognitive and academic performance and daily wellbeing among Aldent University students 13

Impact of diet on reproductive performance in dairy cows in Algeria 14

Study of the effect of antibiotics and probiotics on sperm quality *in vitro* using an automated semen analysis system (CASA) 15

Evaluation of corrosion inhibition effect of pyrimidine derivative on aluminium alloy by electrochemical techniques 16

Measurement of the viscosity of gum arabic 17

Theoretical design and DFT evaluation of d-glucosamine–oxyresveratrol–essential amino acid grafted molecules for enhanced antioxidant activity 18

Prevention of transmission and infection by Parvovirus B19, in children with Hemoglobinopathy, who receive blood transfusions. 19

In vitro seed germination, callus induction, and shoot formation of *Zygophyllum album* L. 21

Novel water-soluble Zn-phthalocyanine complexes enhance foliar zinc bioavailability and concentration-dependent redox homeostasis in *Cucumis sativus* under zinc deficiency 22

Towards chemical contaminants detection in pepper and cucumber: Reporting SERS sensing by a novel gold nanotriangle metal-insulator-metal array 23

Design and (bio)functionalization of isocyanate-bearing cryogels 24

AgNP synthesis using supercritical CO_2 extract of *Lilium ciliatum* leaves 25

Green synthesis of selenium nanoparticles using *Cicer arietinum* L. extract and investigation of their biological activities *in vitro* for new drug development 26

Does life kinetics exercise have an effect on melatonin and cortisol levels in Alzheimer's disease? 27

Smart pesticide detection via hexagonal MIM metasurfaces integrated with deep feed-forward networks 28

Hydrogel form containing drug delivery system for psoriasis treatment potential 29

Bowtie-patterned nanosensor arrays for food safety monitoring 30

Detection of nutrient deficiencies in *Arabidopsis thaliana* using deep learning techniques for smart farming 31

Determining the potential of the marine invasive alien macroalga *Stypopodium schimperi* as a blue economic resource 32

Biogenic gold nanoparticles (AuNPS) from invasive brown macroalga *Stypopodium Schimperi* aqueous extract: Characterization and ecotoxicological potential 33

Synthesis and investigation of ternary nanocomposite fibers 34

Fabrication of TiO_2/h-BN-CdSe based quantum dot-sensitized solar cells 35

Regulatory role of caveolin-1 in doxorubicin-induced SASP and its impact on cancer cell proliferation 36

Effect of life kinetic exercise on BMAL1 and CLOCK in Alzheimer's disease 37

Effects of low temperature stress on pollen germination, tube growth, and antioxidant responses in Turkish olive cultivars 38

Volatile composition of *Lathyrus laxiflorus* subsp. *laxiflorus* by GC-MS/FID analysis 39

Preparation of a drug delivery system including caffeic acid for the inhalation-based treatment of lung cancer 40

Development of active biodegradable poly(3-hydroxybutyrate-co-4-hydroxybutyrate) films enriched with essential oils for food packaging applications 41

Green synthesis of zinc oxide nanoparticles From *Eucalyptus globulus:* Characterization, and investigation of the antimicrobial effects 42

Investigation of the enzyme inhibition effect of different turnip varieties on antioxidants and sugar metabolism 43

Evaluation of anabolic androgenic steroid nandrolone decanoate effects on apoptosis associated genes in pancreatic cells 44

Synthesis of novel bis-hydrazone derivatives and *in silico* evaluation of their COX-2 inhibitory potentials 45

Determination of resveratrol in fresh and heat-treated pomace *Vitis labrusca* by RP-HPLC 46

In silico assessment of the interaction of the natural compound zeaxanthin with insulin, glucocorticoid, and GLP-1 receptors associated with type 2 diabetes 47

Synthesis, characterization and investigation of new multifunctional processing auxiliary materials to improve processability of polyolefins 48

Cytotoxic and anti-inflammatory potential of 2-cyclopenten-1-one against malign melanoma 49

Effects of halophilic PGPR on salt stress and growth parameters in tomato plants 50

Electrochemical determination of glyphosate: Molecular imprinting approach in the presence of nanomaterials 51

Aloe vera L. bitkisinin gizli parmak izlerinin tespitinde kullanımı üzerine bir ön çalışma 52

Palynological studies on *Astragalus* sect. *Malacothrix* (Fabaceae) 53

Su içindeki alüminyum ve florür iyonlarının akıllı telefon uyumlu çift tespiti için mono-sübstitüe rodamin sentezi 54

Roles of EDDHA-derived zinc complexes on growth and antioxidant defense in rice (*Oryza sativa* L.) exposed to salt stress 55

Cytotoxicity of *Origanum majorana* extracts on A549 cells and their radical scavenging activity 56

Development of hyaluronic acid-coated/curcumin-loaded poly(ε-caprolactone) membranes for biofunctional wound dressing applications 57

Innovative approach in food safety: Smart packaging systems with natural pigments 58

Optimizing lettuce cultivars and agrobacterium strain selection for enhanced transformation efficiency using a CRISPR-compatible vector 59

Acetylcholinesterase and butyrylcholinesterase enzyme inhibitory effect of *Ganoderma lucidum* (Reishi) mushroom 60

Carbon-filled polymer composites: structure–property relationships for improved mechanical and thermal performance 61

Development of self-healing anti-corrosive smart epoxy coating material reinforced with chitosan/halloysite nanotubes 62

Yerli üretim tanı kitinde kullanılan antikorların elektrokimyasal validasyonu 63

A study on *MARK* gene family members in pancreatic adenocarcinoma 64

Development of a novel polymeric membrane for cationic dye adsorption 65

Uncovering the soil impact of wastewater irrigation: A case study from Konya, Türkiye 66

Investigation of photosensitizer properties of zinc phthalocyanines in photodynamic therapy by photophysicochemical properties 67

Design of a lipoic acid–based thioester polymer functionalized with tryptophan for drug release 68

β-Glucan production from *Saccharomyces cerevisiae* under submerged fermentation 69

Production, extraction and characterization of microbial mannoprotein 70

Controlled Sr(II) ion release from injectable electroactive hydrogels with potential for the treatment of infections 71

Supercritical carbondioxide extraction of *Nigella sativa* L. seed oil: fatty acid composition, nutritional energy and antimicrobial activity 72

Characterization and enzyme kinetic study of serine protease subtilisin carlsberg immobilized on biochar-chitosan composite carrier obtained from waste biomass 73

Effect of drying method and process conditions on the physicochemical and functional properties of tomato pomace powder 74

Preparation and antibacterial activity of Ag_2O nanoparticles from *Cedrus libani* 75

Analytical determination of the active pharmaceutical ingredient propranolol 76

Advanced polymeric adsorbents for the treatment of arsenic- and selenium-contaminated wastewater 77

Osmanlı döneminden günümüze gül yağı distilasyonu 78

Development of polyvinyl alcohol based bioactive cosmetic masks 79

Bacillus subtilis offers insights into microbial adaptation under Martian conditions 80

Computational insights into the antioxidant and anticancer mechanisms of apigenin 81

Transcript levels of ZDHHC protein palmitoyltransferases in granulosa cells isolated from the ovaries of PCOS and non-PCOS women 82

Synthesis, characterization and investigation of aggregation properties of non-peripheral octa-substituted Nickel(II), Zinc(II) Copper (II) phthalocyanines 83

COVID-19'da IL6 ve TMPRSS11A polimorfizmlerinin genotip kombinasyonları ile hastalık şiddeti arasındaki bağlantı 84

Mardin'de unutulmaya yüz tutmuş gastronomik bir değerin incelenmesi ve duyusal analiz ile değerlendirilmesi 85

Bir Alman çoban köpeğinde tek yavru sendromuna (single pup syndrome) bağlı olarak şekillenen güç doğum olgusu 86

Investigation of the mechanical and antioxidant properties of bioactive wound dressings containing grape seed oil 87

Çeşitli analitlerin eş zamanlı tayini için elektrokimyasal sensörler 88

Farklı fasulyeler ile üretilen cipslerde tüketici beğenisinin değerlendirilmesi 89

Assessment of calibration techniques for the determination of cadmium at different levels in sage and rosehip tea samples by flame atomic absorption spectrometry 90

Effect of St. John's wort and coconut oil blends on the structural and thermal properties of protein-based films for potential biomedical applications 91

Fumigant toxicity of *Clinopodium serpyllifolium* subsp. *serpyllifolium* essential oil against different larval stages of *Tenebrio molitor* (Coleoptera: Tenebrionidae) 92

Synergistic antioxidant effect of squalene and saponin in a d-galactose-induced aging model 93

Identification of novel miRNAs in tobacco (*Nicotiana tabacum* L.) targeting black shank and powdery mildew genome 94

Cuscuta epithymum ekstresinin fenolik içeriği ile biyoaktivitelerinin belirlenmesi 95

Determination of total phenolic, flavonoid content, and antioxidant activity of rose of jericho (*Anastatica hierochuntica*) 96

Construction of RuCo decorated poly(2-hydroxy methacrylamide) polymer brush grafted magnetic nanoparticles as a heterogeneous catalyst for degradation of some azo dyes. 97

Predicting polymer–drug compatibility for queuine and gemcitabine via molecular simulations 98

Development and characterization of tannic acid crosslinked poly(vinyl alcohol) films 99

Eco-friendly synthesis and photocatalytic applications of zinc oxide nanoparticles (ZnO-NPs) using extract derived from agro-waste hawthorn (*Crataegus monogyna*) 100

First complete mitochondrial DNA data provided for Turkish Hamster (*Mesocricetus brandti* Nehring 1898) 101

Odyolojik veriler kullanılarak makine öğrenmesi ile işitme cihazlarında hoparlör tipinin tahmini: Random forest yaklaşımı 102

Isolation of bacteriocin-producing *Enterococcus* strains from traditional cheeses 103

Investigation of feeding interactions between the Randall's threadfin bream (*Nemipterus randalli*) and the common pandora (*Pagellus erythrinus*), two co-occurring fish species in Gökova bay, using stable isotope analysis 104

Cyclotriphosphazene derivatives containing carbazole units and the investigation of their photophysical properties 105

Determination the pathogenicity and virulence of *Fusarium* species isolated from Amasya, Türkiye, on sugar beet 106

Investigation of the photodynamic therapy potential of water-soluble phthalocyanine compounds containing pyridine substituents on breast cancer cell line 107

Management of swallowed capsules filled with drugs in intensive care 108

Experimental and theoretical investigations of semi-lethal dose (D_{50}) values for bacterial population 109

Lactarius deliciosus (L.) Gray özütlerinin gökkuşağı alabalığı (*Oncorhynchus mykiss*, Walbaum, 1792) filetolarının raf ömrü üzerine etkisi 110

Yeast microflora of milk kefir beverages fermented with various grains 111

Identification of foot-and-mouth disease virus antigenic peptide via SERS 112

Integration of artificial intelligence in wastewater treatment for sustainable biogas generation 113

Structural elucidation and antimicrobial potentials of pyrazoline compounds derived from chalcone intermediates 114

UV ve filtrasyon tabanlı balast suyu arıtım sistemlerinin saha performansı üzerine bir değerlendirme 115

Determining the recent status of non-native marine fish species in the Aegean coast of Türkiye 116

Assessing the impact of microbial dysbiosis on disease pathogenesis through a one health perspective 117

Synthesis and Characterization of Ester-Based Hindered Amine Light Stabilizers (HALS) in Polymers 118

In silico analysis of missense SNPs in the *CDH9* gene 119

Coating of Mg alloys with nano hydroxyapatite (HA) to be used as biodegradable biomaterials 120

Synthesis, characterization and *in silico* anticholinesterase inhibitory activity of new hydrazide-hydrazone derivatives 121

Cistus laurifolius L. (karağan) bitki ekstraktının kolon kanseri hücre hattında (HCT 116) anti kanser etkilerinin incelenmesi 122

Catalytic performances of silica gel supported monometallic (Co, Nb, Cu) catalysts in hydrogen production via $NaBH_4$ methanolysis 123

Integrative bioinformatics reveals crosstalk between MIF and HER2 signaling networks in breast and colorectal cancer 124

Development of biodegradable poly(lactic acid) composites reinforced with orange peel powder 125

Altered serum levels of netrin-4 and neogenin reflect tumor progression in glioma patients 126

Agomelatine may alleviate the LPS-induced ER stress response and apoptotic signaling in human embryonic kidney cells 127

Synergistic mechanism of graphene oxide-composite silver nanoparticles combined with gemcitabine in pancreatic cancer 128

Impact of plant-based dietary patterns on breast cancer prevention 129

Copper oxide nanoparticles synthesized in a deep eutectic solvent for efficient metronidazole adsorption 130

Next-generation inositol phosphate derivatives as mechanistic inhibitors of HIV-1 assembly 131

Synthesis of new sensor based on quinolinium-containing cyanobiphenyl 132

Effect of trimetazidine on detrusor contractility in a mouse model of L-NAME-induced overactive bladder 133

Investigation of the genotoxicological potential of desipramine, an active substance used in antidepressant drugs, by *in vitro* test methods 134

Chronic inflammation response in acute myeloid leukemia (AML) 135

Evaluating the potential of royal jelly as a tyrosinase inhibitor 136

Biochar-assisted removal of anionic textile dyes from model waste water 137

The effect of vacuum PA/PE packaging on certain quality characteristics during the ripening process in classical white cheese production 138

Borik asidin melanom hücre hattı üzerindeki antikanser etkisinin araştırılması 139

Development of impact-resistant, halogen-free, flame-retardant PBT-based composites for use in the automotive industry 140

Synthesis of biopolymer-based quercetin delivery systems using alginate beads: *In vitro* antioxidant and release kinetic analyses 141

Recombinant production of glycoprotein E of Varicellovirus bovinealpha1 in the *Pichia pastoris* yeast expression system 142

Chemical characterization and enantiomeric distribution of Bulgarian lavender (*Lavandula angustifolia* Mill.) cultivars growing in Türkiye 143

Investigation of insecticidal effects of some plant seed oils on adults of *Acanthoscelides obtectus* (Say, 1831) (Coleoptera: Chrysomelidae) 144

The diagnostic importance of circulating subfatin levels in the development of obesity 145

Sustainable gold nanoparticle fabrication from *Corylus maxima* leaves via microwave-assisted extraction 146

The effect of schiff base–derived 4,5-dihydro-1*h*-1,2,4-triazol-5-one compound on serum protein expression and lipid profile in wistar albino rats 147

Evaluation of the *in vitro* genotoxic and antigenotoxic potential of *Geranium robertianum* extract 148

An extensive research on activated carbon (AC) for preparation, characterization and improvement of properties with modification methods 149

Production, import and consumption distribution of activated carbon (AC) in Türkiye 150

Cytotoxic effects of antidiabetic drug metformin in Mcf-7 cells 151

Comparative analysis of the effects of stable and classical vitamin C forms (L-ascorbic acid and 3-O-ethyl ascorbic acid) on antioxidant activity, cell viability, and clonogenic capacity in skin cells 152

Cucurbita pepo'da biyotik stresle ilişkili mikroRNA'ların tanımlanması ve fonksiyonel karakterizasyonu 153

Antidiabetic enzyme inhibition and kinetic behavior of water-soluble morpholine-functionalized axially disubstituted silicon phthalocyanines 154

Uncovering hidden patterns: The significance of water quality trend analysis 156

Determining the vulnerability of groundwater to pollution in the Develi basin (Kayseri) using the DRASTIC method 157

A rapid and eco-friendly route for the synthesis of mono- and bimetallic nanoparticles 158

Investigation of the genotoxic effects of borax decahydrate using micronucleus assay 159

Investigation of the protective potential of boric acid against the genotoxic effects induced by aspartame 160

Evaluation of cytotoxic effects of capecitabine and epigallocatechin gallate combination on a human breast cancer cell line 161

Comparison of *in silico* tools used for predicting the functional effects of polymorphisms in veterinary genetics 162

The use of biotechnology and nanotechnology in parasitology 163

Secondary structures of mitochondrial genes in the classification of *Salmo* species in Türkiye 164

Human health evaluation of drinking water sources in Kütahya province 165

Reorganization of pollen tube cell wall under low temperature conditions in *Camellia sinensis* 166

Total phenolic and flavonoid contents and antioxidant potential of *Vincetoxicum fuscatum* subsp. *fuscatum* seeds 167

Effects of thymoquinone in a surgically induced rat endometriosis model 168

Coverage–confidence paradox in Turkey: A secondary analysis of childhood vaccination and public attitudes (1980–2024) 169

Effects of some postharvest treatments on the storage of nectarine fruits 170

Combined evaluation of inflammatory biomarkers and circulating miRNA-29c in diabetic nephropathy 171

Investigation of toxigenic *Bacillus cereus* in milk and milk-based desserts 172

Magnesium and calcium complexes of curcumin and quercetin: Insights into cell viability, oxidative stress, and antioxidant potential 173

Design and synthesis of amino acid–hydrazone hybrids as dual Bcl-2/NF-κB inhibitors 174

Kalp yetmezliği tedavisinde kullanılan bazı etken maddelerin analizi için kromatografik yöntemlerin geliştirilmesi 175

Synthesis, structural characterization and computational ADME analysis of a New Triazole-Based Cu(II) coordination compound 176

Investigation of the antitumor activity of *Eremurus spectabilis* M. Bieb. (çiriş herb) plant extracts in the process of hepatocellular carcinogenesis induced experimentally with diethylnitrosamine in rats 177

Phytoremediation-oriented Evaluation of Nickel Stress Responses in *Anubias nana* Engl. grown in aquatic systems..... 178

A bibliometric analyse of scientific studies on the invasive species *Lepomis gibbosus*..... 179

Synthesis of functional nanohybrid materials through *in situ* copolymerization 180

Yüksek pH ve tuzluluk koşullarında yerli EDDHA-Fe şelatının gübre performansı ve sürdürülebilir tarım açısından potansiyelinin araştırılması..... 181

Development of a cationic surfactant-selective glassy carbon electrode for potentiometric determination of didecyldimethylammonium chloride..... 182

Efficient microwave-assisted synthesis of novel compounds by the reaction of penta-1,4-diene-3-one derivatives with N,N-dimethyl barbituric acid 183

Fenolik bileşiklerin tayini için polifenol oksidaz temelli biyosensör tasarlanması..... 184

Resveratrol'ün 4T1 meme kanseri hücreleri üzerinde sitotoksik etkisinin değerlendirilmesi..... 185

Determination of the association of TLR2 rs5743708 and rs121917864 polymorphisms with endometrial cancer risk 186

Selüloz esaslı kompozitlerin 2. tip fotopolimerizasyon yöntemiyle hazırlanması*..... 189

Atık kahve telvesinden türetilen mezogözenekli karbon katkılı PVDF Bazlı PEM yakıt pili membranlarının geliştirilmesi..... 190

A new distribution area of the endemic *Trigonella coerulescens* subsp. *ayvalikensis* (Fabaceae) in Türkiye 191

Ionic liquid–assisted photoluminescence enhancement in CASN:Eu^{2+}–pyranine composites..... 192

Green protein extraction from hazelnut meal using deep eutectic solvents..... 193

Machine learning-driven identification of allosteric networks for the rational design of shark-derived single-domain antibodies..... 194

Farklı coğrafi kökenli sarımsak ve kabuklarının kimyasal parmak izi analizi: FTIR-2D-COS ve HPLC-DAD ile bütünleşik bir yaklaşım 195

Histological investigation of the effects of chronic thiamethoxam exposure on the digestive gland and kidney tissues of *Lymnaea stagnalis*..... 196

Current applications of CRISPR-cas technologies in food microbiology..... 197

Extraction of antioxidants from food waste and its contribution to sustainability..... 198

Visible-light-induced degradation of reactive orange 16 using IRMOF-3: A solar photocatalysis approach 199

The effects of MTHFR gene polymorphisms (C677T, A1298C) and homocysteine levels on the clinical progression of COVID-19 200

Evaluation of the cytotoxic effect of vortioxetine on various cancer cell lines 201

Vortioksetinin çeşitli kanser hücre hatlarındaki sitotoksik etkisinin değerlendirilmesi 202

Screen-printed carbon electrode integrated with feather-like Au-Ag-Co trimetallic composite: An advanced sensor for electrochemical determination of sertraline HCl 203

Investigation of the cytotoxic effect of tizanidine on different cell lines 204

Investigation of the use of bio-based plasticizers in Vinyl (PVC) disposable glove production and their effects on material properties 205

Electrochemical enhancement of modified ITO electrodes for high-performance supercapacitor applications 206

Investigation of the relationship between physical activity level and body awareness in ambulance drivers 207

Advances in 3D graphene foam electrodes for biosensing applications 208

The importance of early detection in Alzheimer's disease: Advancing body-fluid biomarker detection with point-of-care devices 209

Biyokontrol ajanlarının etkisi altındaki *Fusarium spp.*'de transkriptomik incelemeler 210

Farklı esansiyel yağlar içeren pla temelli yara örtülerinin üretimi ve mekanik özelliklerinin incelenmesi 211

Isolation, molecular typing, and investigation of biotechnological potential of actinobacteria from soils in Ardahan province 212

Seasonal changes in phosphatidylinositol (PI) Fatty acid content in muscle tissues of male and female individuals of *Silurus triostegus* 213

Analysis of tumor mutational burden and mutation status in immunotherapy-treated lung adenocarcinomas 214

Antibacterial hydrogels containing a Cu(II) hydrazone complex: Synthesis, characterization, and in vitro activity 215

Acidic deep eutectic solvent catalyst for efficient conversion of levulinic acid to n-butyl levulinate fuel bioadditive 216

Helichrysm arenarium subsp. *erzincanicum* türünün fitokimyasal içeriğinin belirlenmesi ve antioksidan kapasitesinin değerlendirilmesi 217

C-QD ve ZnO-QD'ların hidrotermal sentez yöntemi ile üretimi ve güneş hücrelerinde uygulanmasının araştırılması 218

Histological insights into endometrial microbiota: Implications for fertility and IVF outcomes 219

Metilen mavisi adsorpsiyonunda kullanılmak üzere mısır atıklarından manyetik biyochar üretimi ve karakterizasyonu 220

Cold plasma in the food industry: Mechanisms, product quality and safety perspectives 221

Plantago lanceolata ekstraktı ve çinko-oksit nanopartikülleri ile zenginleştirilmiş çift katmanlı fonksiyonel mikroiğne üretimi ve karakterizasyonu 222

Examination of muscle strength and reflexes in male adolescent rats with streptozotocin-induced diabetes mellitus 223

The impact of gamma rays on soybean germination and seedlings 224

Comperative analysis of three genomic DNA isolation methods in *Simulium bezzii* 225

Synergistic effects of ruxolitinib and *Liquidambar orientalis* extract on MDA-MB-231 breast cancer cells 226

Lilium akkussianum and conservation priorities for Turkey's endemic *Lilium* Species: Habitat requirements and threat analysis 227

From chromatogram to confirmation: Advanced detection of VX nerve agent and related compounds 228

Investigation of programmed cell death during larval-pupal metamorphosis on the posterior silk gland of the *Galleria mellonella* 229

Synthesis of new triazoles as acetylcholinesterase inhibitors 230

The effects of microplastics on soil and plant ecophysiology: Current findings on pollutant transfer from source to plant 231

Newly developed bio-oil-interacted cellulose acetate micro-structured composite adsorbent for efficient dye removal 232

Eco-friendly synthesis of selenium nanoparticles using *Leptolyngbya* sp.: Physico-chemical characterization and bioactivity assessment 233

Dye removal efficiency of bio-oil reinforced flat-sheet cellulose acetate composites as potential membrane materials 234

Synthesis and antioxidant properties of potential dual-acting acetylcholinesterase inhibitors 235

Synthesis of the various macro initiator for production of the blok/graft copolymers via “living”/controlled radical polymerization (CRP) techniques 237

Development of nanoparticle based approaches for the conservation of some paper artifacts 238

Broussonetia papyrifera'dan yeni tanımlanan 1,3-difenilpropanların asetilkolinesteraz enzimi üzerindeki inhibitör etkilerinin *in-silico* olarak incelenmesi 239

Pharmacological uses of species belonging to the Lamiaceae family on the campus of Uşak University 240

Synthesis and tyrosinase inhibition of 1-(4-fluorobenzyl)piperazine-based dithiocarbamates 241

Effects of heat treatment on gga-miR-30c-5p, gga-miR-191-5p, and gga-miR-215-5p in poultry eggs . 242

RNA isolation from three-dimensional saos-2 cultures in a collagen/keratin/alginate hydrogel 243

Synthesis and characterization of biodegradable polyester by ring-opening polymerization (ROP) 244

Atıksu arıtma tesislerinde karbon ayak izi: Türkiye’deki mevcut durum 245

Evaluation of antibacterial potential of different parts of *Vincetoxicum hirundinaria* against *Enterobacter cloacae* 246

Solvent-dependent differences in the DPPH antioxidant activity of bee pollen extracts 247

Metagenomic analysis of the olive rhizosphere microbiome 248

Membrane cholesterol modulation Alters P2x7-mediated membrane currents but not cytoskeletal reorganization in macrophages 249

In silico evaluation of potential inhibitors against *Moraxella catarrhalis* 3-oxoacyl-[acyl-carrier-protein] reductase (FabG) 250

Acute effects of bacterial lipopolysaccaride on liver of female rats: Assestment of histopathological changes 251

TLR4/MYD88/ NF-KB sinyal yolağı 252

Dose-dependent cytotoxic effect of Carbidopa on U-87 MG human glioblastoma cells 253

Hydrazone-functionalized diphenylurea derivatives: Synthesis, structural characterization, and comprehensive biological activity evaluation 254

Development of high-sulfonation sPEEK membranes containing s-TiO_2 nanoparticles for direct methanol fuel cell (DMFC) applications 255

Silica-supported silicotungstic acid incorporated high-DS sPEEK membranes for hydrogen PEMFC applications 256

Synthesis of eudragit RS100-coated juglone-Ag encapsulated PLGA nanoparticles for the treatment of *Helicobacter pylori* 257

Eudragit-coated PLGA nanoparticles encapsulating CAPE–Ag complex for gastric cancer therapy 258

Eudragit-functionalised PLGA nanoparticles encapsulating juglone–Cu complexes as a promising delivery system against *Helicobacter pylori* 259

Sustainable waste recycling strategies in the blue economy 260

Podmore extract (apis totale) content analysis and *in vivo* animal studies 261

Identification of SNPs from RNA-seq data in tolerant soybean mutants 262

Keratin-enhanced hydrogels: Structural and functional characterization for tissue engineering 263

Fabrication and characterization of polyvinyl alcohol/gelatin/hyaluronic acid based microneedle patches for transdermal delivery of amphotericin B 264

Tunicate species diversity in İzmir Bay 265

Non-enzymatic electrochemical sensor design of pencil graphite electrode modified with poly(L-proline) and graphene for sensitive detection of folic acid 266

Synthesis, characterization and anticancer evaluation of novel urea derivatives 268

Computational study on the molecular, electronic, and spectroscopic properties of 3-ethyl-4-[3-methoxy-2-(4-methoxybenzoyloxy)-benzylideneamino]-4,5-dihydro-1*H*-1,2,4-triazol-5-one 269

Investigation of antibacterial, antifungal, antibiofilm and synergistic effects of *Satureja thymbra* L. plant extracts against bacteria and fungi 270

Investigation of biocompatibility and anticancer activities of *Lavandula intermedia* and *Lavandula angustifolia* on breast cancer (MCF-7) and healthy mouse fibroblast (L929) cell lines 271

Investigation of genetic diversity in barley (*Hordeum vulgare* L.) varieties grown in Türkiye using ISSR molecular markers 272

Determination of *in vitro* biological activity of firethorn plant fruits 273

The role and impact of eco-labels in seafood marketing 274

The effect of 1-methylcyclopropane treatments on phenolic compounds in 'Ekmek' quince fruit 275

Preharvest salicylic acid treatments can improve fruit quality in '0900 Ziraat' cherry fruit 276

Rize-sourced hazelnut shell ash as a green corrosion inhibitor for Fe metal in 1 wt.% NaCl: Electrochemical evaluation and mechanistic insights 277

Cobalt oxide/halloysite nanotubes for enhanced electrochemical sensing of tetracycline 278

Evaluating the phytoremediation potential of *Hygrophila corymbosa* under lead stress: Physiological insights in freshwater environments 279

Investigation of cytotoxic and anti-angiogenic effects of apigenin in breast cancer cell line 280

Synthesis, characterization, and evaluation of cytotoxic activities of *n*-phenyl-*n'*-(4-pyridylmethyl)urea derivatives in breast cancer cell lines 281

Relationship of polymorphisms in *PITX1, PITX2, LHX3, PROP1* and *POU1F1* genes with litter size and growth traits in saanen goats 282

Evaluation of the capacitive behavior of MWCNTs to explore their potential applications in supercapacitor electrodes 283

Synthesis of porous carbon structures from coal via molten salt activation and HF acid treatment for hydrogen storage 284

Determination of meat consumption preferences by analytical hierarchy process (AHP) 285

An *In-silico* platform for predicting magnetic resonance imaging (MRI) contrast properties of diamagnetic chemical exchange saturation transfer (DIACEST) agents 286

Biomarker evidence of metolachlor-driven oxidative stress in rainbow trout 287

Co-toxicity of pesticides and nano/microplastics in aquatic systems: Implications for fish models 288

Impact of agricultural herbicides on aquatic ecosystems: Case of aclonifen 289

Neuroinflammation in chronic urticaria: A bibliometric analysis of global research output

Eralda Lekli[1,2*] (ORCID:0000-0003-3041-8910,)
Mehmet Hoxha[1,3] (ORCID: 0000-0001-8829-6931)

[1]University of Medicine, Faculty of Medicine, Department of Internal Diseases, Tirana, Albania.
[2] Salus Hospital Tirana, Department of Allergology, Tirana, Albania.
[3]University Hospital Mother Teresa, Service of Allergology, Tirana, Albania

Abstract

Chronic urticaria (CU), particularly chronic spontaneous urticaria (CSU), is a complex inflammatory skin disorder characterized by recurrent wheals and/or angioedema lasting longer than six weeks. (Zuberbier et al. 2022) While mast-cell activation has been considered central to disease physiology, emerging evidence indicates that neuro-immune pathways and neuroinflammation may also contribute to symptom persistence and disease severity. Chronic urticaria, like atopic dermatitis, is shaped by communication between immune cells and sensory nerves, and this connection appears to aggravate the disease. (Yang et al. 2025) Interest in the neuro-inflammatory dimension of CU has grown, yet the overall volume, distribution, and type of publications addressing this intersection remain unclear. We aimed to evaluate the scientific output related to neuroinflammation and chronic urticaria. A structured search was conducted using Google Scholar with above keywords, summarizing publication trends across all years, the last 5 years, and the year 2025, while comparing the proportion of review versus non review articles and documenting the presence of patents and citations. A total of 3830 publications were identified across all years, 1150(30.03 %) review articles, 17.75% or 680 publications marked as patents and 7.83% or 300 citations only entries. Out of total, 2280(59.53 %) were published during 2021-2025, with 754(19.68 %) review articles, and 590(15.4 %) were published in 2025, out of them 223(5.82%) review articles. The proportion of review articles was increased to 37.8% of related publication during 2025, from 33.1% in past 5 years. The majority of publications focused on neuro-immune signalling, mast-cell–neuronal interactions, psychological stress pathways. Although the total body of literature addressing CU is considerable, publications specifically integrating neuroinflammation remain limited, suggesting increasing interest in recent years. These data highlight the need for more targeted mechanistic and clinical research exploring the neuro-immune axis in chronic urticaria.

The influence of self-prepared foot care product on foot microbiome

Katarzyna Duda – Grychtol[1*] (https://orcid.org/0009-0008-7306-9611), Julia Kościołek[1]

[1] The Silesian Academy of Medical Science in Katowice, Katowice, Poland

Abstract

The feet are one of the most unique and heterogeneous microbial niches of human body with areas that differ by skin thickness, anatomical features, and distribution of sweat glands, pH and the availability of oxygen. Healthy skin of the foot is colonized by different microorganisms including bacteria like *Corynebacteriaceae*, *Micrococcaceae*, *Propionibacteriacea*e, *Streptococcaceae*. The most common fungi present on the feet are *Malassezzia*, *Cryptococcus*, *Aspergillus*, *Candida*, *Epidermophyton, Microsporum* and *Trichophyton*. Different factors can promoting growth of foot microbiome lead to eubiosis but in the other side destroyed this homeostasis and increased susceptibility to infection, skin disease and chronic inflammation. The aim of this study was to prove how self-prepare foot care products influenced on foot microbiome. Two foot cream were prepared with different active components. Cosmetics were tested during 30-days with 30-days break between each of them. Rodact Contact test for yeast and molds and for all microorganisms were used, before start the project in the middle of research and after used creams to the end. Colonies were characterized and dyed using Gram method. Trichoscopic camera were used in order to assess the condition of foot. Self-prepared cosmetics for foot influenced on skin foot hydration, moreover reduced excessive keratosis of the epidermis. In all study participants modification of foot microbiome were observed. Skincare routine 2-times per day and carefully selected active ingredients had beneficial effect on foot skin condition and foot microbiome. Inulin added to one of the creams influenced to a significant extent on diversity of bacteria, at the same time reduce quantity of fungi.

Keywords: foot cosmetics, microbiome, eubiosis

[2] Toxicology Unit, Forensic Medicine Department, Maghlaoui Mila Public Hospital

Abstract

The misuse of psychoactive prescription drugs has now become a new form of addiction worldwide.The World Health Organization highlights an increase in the non-medical use of prescription medications such as Pregabalin, particularly among young people.Although this substance is often considered less dangerous than illicit drugs, it presents a significant risk of abuse and dependence.Pregabalin appears to have a high addictive potential, likely due to its rapid absorption and shorter onset of action. The desired effects include euphoria, relaxation, and increased sociability. The euphoric effect is generally very pronounced and rapid. Sedation, dissociative effects, disinhibition, and hallucinations have also been described. Typically, these effects occur at doses far exceeding the maximum authorized oral dose of 600 mg.This is a prospective and analytical study, conducted during the year 2023, involving 133 patients attending addiction treatment centers.The collected samples were subjected to screening by an immunochemical method (EMIT) and quantification by liquid chromatography (HPLC-UV) after developing and validating a technique for the urinary assay of pregabalin and comparing the results with rapid tests.The assay revealed the presence of pregabalin in 32.3% of the study population.Liquid chromatography (HPLC-UV) is much more sensitive and specific than the immunochemical method (EMIT).Drug use can affect all individuals, regardless of age, gender, or socio-professional level. A positive result is highly likely if consumption is recent and if the subject is a regular user at doses above 600mg.Initial screening in psychiatric centers is recommended to aid in the diagnosis and appropriate management of addicts. Knowledge of the limitations of urinary screening by EMIT and rapid tests is essential for their optimal use. Chromatographic methods are the reference methods for the identification and quantification of pregabalin.

Keywords: Pregabalin, Addicts, Management, HPLC-UV, EMIT, Rapid test.

[5]Department of Imaging, American Hospital, Tirana, Albania

Abstract

Temporomandibular disorders (TMDs) are a common cause of orofacial pain and dysfunction. Magnetic resonance imaging (MRI) is considered the gold standard for evaluating the temporomandibular joint (TMJ), providing direct visualization of the disc, joint spaces, and associated degenerative or inflammatory changes. This study aimed to investigate the association between disc displacement, degenerative changes, and inflammatory activity in TMJ using MRI. A retrospective review of TMJ MRI examinations was performed. Imaging in closed and open-mouth positions using T1-weighted, T2-weighted, and Proton Density (PD) sequences was analyzed for disc position, degenerative alterations, and signs of inflammation. Disc displacement was identified in most patients, with disc displacement without reduction (DDwoR) being the predominant finding. Degenerative changes were frequently associated with displacement patterns. MRI also revealed joint effusion and bone marrow edema, emphasizing its ability to detect early inflammatory features not visible on other imaging modalities. MRI provides a comprehensive evaluation of TMJ pathology by detecting disc displacement, chronic damage, and active inflammatory changes. These findings emphasize the clinical importance of DDwoR as the highest-risk subgroup and support the use of MRI to differentiate chronic from active disease, guiding management. This study also establishes a foundation for future prospective research integrating clinical data with MRI to develop interpretation models for improved diagnosis and management.

ORAL PRESENTATION

The effect of collagen supplementation on skin structure and signs of aging

Klaudia Śmigielska[1*]

[1]Śląska Wyższa Szkoła Medyczna, Cosmetology, Katowice, Poland

Abstract

Skin aging involves complex alterations within the dermis, where degradation of collagen, impaired fibroblast activity and fragmentation of the extracellular matrix (ECM) progressively weaken tissue architecture. With age, the number of dermal fibroblasts decreases by approximately 35%, and remaining cells, adopt a senescent SASP phenotype, contributing to chronic low-grade inflammation and accelerated breakdown of structural proteins. Increased activity of matrix metalloproteinases (MMPs), without a parallel rise in their inhibitors (TIMPs), further amplifies collagen type I loss. These processes are accompanied by protein glycation and reduced synthesis of glycosaminoglycans, including hyaluronic acid, lowering the skin's water-binding capacity and impairing its biomechanical properties. Interest in oral collagen supplementation arises from its ability to deliver low-molecular-weight bioactive peptides that are absorbed into the bloodstream and act as signaling molecules for fibroblasts. Clinical studies demonstrate increased synthesis of collagen type I, elastin and hyaluronic acid after 8 - 12 weeks of regular supplementation. Three randomized, double-blind, placebo-controlled trials consistently reported significant improvements in skin hydration, elasticity, density and wrinkle reduction in individuals using collagen peptides at daily doses of 1650 - 3300 mg. These findings indicate that oral collagen may serve as a valuable adjunct to regenerative cosmetic procedures, working synergistically with treatments that stimulate fibroblast activity. This benefit, however, depends on the use of standardized preparations with defined peptide composition and molecular weight. Despite promising outcomes, further research is required, particularly regarding the long-term persistence of effects and populations other than women over 30 years of age.

Keywords: collagen peptides, skin aging, fibroblasts, hydration, elasticity

Oleic acid nitrogen derivatives as antistatic additives

[1]V.M. Abbasov, [1]A.A. Kangarli, [1]N.I. Mursalov, [1,2]D.B. Aghamalieva, [1]E.K. Hasanov

[1]Institute of Petrochemical Processes, Ministry of Science and Education
[2]Azerbaijan State Oil and Industry University, Azerbaijan

Abstract

This research study is dedicated to synthesizing nitrogen-containing organic derivatives of oleic acid and investigating their effects on the antistatic properties of diesel fuel. Nitrogen derivatives of oleic acid were synthesized using triethylenetetramine and polyethylene polyamine. These synthesized derivatives were added to diesel fuel in various concentrations, and their electrical conductivity and antistatic effects were examined. The test results determined that amidoamines synthesized from oleic acid with triethylenetetramine and polyethylene polyamine exhibited the highest electrical conductivity at a concentration of 0.05%. In particular, amidoamine compounds synthesized with PEPA enhanced the electrical conductivity of diesel fuel more effectively, preventing the accumulation of static electricity. Based on the obtained results, Sample No. 3 demonstrated the highest antistatic effect and is recommended as the most effective additive.

Keywords: oleic acid, triethylenetetramine, polyethylene polyamine, amidoamine, diesel fuel.

Ultrastructural analysis of the midgut epithelium of *Lithobius forfocatus* (Myriapoda, Chilopoda) exposed to different concentrations of nanostyrene

Agata Aleksa[1*] ORCID: 0009-0003-7492-8469, Magdalena Rost-Roszkowska[1*] ORCID:0000-0001-7124-842, Łukasz Chajec[1*] 0000-0001-6455-9063

[*1]University of Silesia in Katowice, Faculty of Natural Sciences, Institute of Biology, Biotechnology and Environmental Protection, Bankowa 9, 40-007 Katowice, Poland

Abstract

The occurrence of nanoplastics (NPs) in terrestrial and aquatic environments is becoming a growing ecological concern. Although numerous studies have confirmed the negative effects of NPs on living organisms, their impact on soil ecosystems is still insufficiently understood. One of the nanoplastics frequently detected in soil is nanostyrene, formed by the breakdown of styrene into micro- and then nanoparticles up to 100 nm in size. Such fine particles can penetrate cell membranes and accumulate within cells and their organelles. Therefore, our study compared the effects of lower and higher concentrations of nanostyrene in soil to determine whether differences in its concentration induce different changes in the midgut cells of the centipede *Lithobius forficatus*. The focus was on characterising the structural and ultrastructural changes occurring in the digestive cells. Transmission electron microscopy (TEM) was used to analyse the midgut epithelium after exposure to nanostyrene at concentrations of 10 mg and 100 mg per kg soil dry weight for 1 and 3 months. The study included observation of ultrastructural changes, signs of autophagic processes and variation in the amount of reserved material over time. The results indicate that the presence of nanostyrene affects the organisation of the apical part of the cytoplasm of digestive cells, highlighting the need for further studies on the effects of nanoplastics on soil organisms and ecosystem functioning.

Keywords: autophagy, ecotoxicology, nanotoxicology, ultrastructure

Assessing the impact of breakfast consumption on cognitive and academic performance and daily wellbeing among Aldent University students

Enkelejda Trebicka[1]

*[1]Aldent University, Faculty of Medical Thecnical Sciences, Tirana, Albania.

Abstract

Regular breakfast consumption plays a crucial role in the physical and mental well-being of students. According to the World Health Organization (WHO), a healthy breakfast contributes to better concentration, sustained energy levels throughout the day, and a reduced risk of developing metabolic disorders at a young age. A self-administered questionnaire was used to assess breakfast consumption habits among students, their knowledge regarding its nutritional components, and the side effects of skipping this meal. The study included 308 participants from Aldent University (276 females and 32 males). Questionnaires were distributed electronically to students, who were encouraged to respond honestly. Of the respondents, 94.5% belonged to the 18–22 age group. Nearly half of the participants (50.3%) reported consuming breakfast regularly, while 49.7% did not. The main reason for skipping breakfast was lack of time (57.3%). Furthermore, 44.8% of those who skipped breakfast reported feeling low in energy throughout the day, and 56% experienced headaches. Additionally, 76.3% of the respondents believed that eating breakfast improves academic performance. The findings of this study show that a considerable proportion of students do not consume breakfast regularly, mainly due to time constraints. This behavior is associated with noticeable consequences for daily well-being, such as fatigue and headaches, and may negatively impact academic performance. Although most students are aware of the importance of breakfast, their eating habits do not reflect this understanding. These results highlight the need for awareness-raising and educational programs that promote healthy dietary habits, with a special focus on breakfast as an essential meal for academic success and long-term health.

Keywords: breakfast consumption, side effects, students, academic performance.

Impact of diet on reproductive performance in dairy cows in Algeria

Kalem.Ammar[1], Hadj Omar Karima[1], Daoudi Zerrouki.Nacira[2], Djallel Adel[1]

[1]Laboratory of Biotechnology in Animal Reproduction (LBRA), Institute of Veterinary Sciences, University of Blida 1, Blida, Algeria
[2]Natural Resources Laboratory. Faculty of Biological Sciences and Agronomic Sciences. University of Tizi-Ouzou. Algeria.

Abstract

The aim of this study was to assess the effect of feed imbalance on the reproductive parameters of cows in production. A total of 120 dairy cows belonging to 4 farms located in the Tizi-Ouzou region were monitored over a period of 7 months. These cows were housed in tie-stall housing. The energy and nitrogen levels of the rations distributed were estimated based on the nutritional value of the various feeds comprising the daily ration distributed, as well as the type of concentrate supplemented. Thus, an estimate of the intakes of the basic and total rations was compared with the requirements of the different categories of females in the herds of the four farms. The effect of these intakes on the animals was assessed in terms of body condition score and reproductive parameters. This study revealed that the rationing implemented on the four farms was unbalanced and did not take into account either the production level or the physiological condition and stage of the female. Statistical analysis of the recorded data revealed intervals between calving and calving ranging from 380 to 400 days and between calving and insemination varying between 78 and 130 days, with a first insemination success rate ranging from 20 to 62% and a high repeat breeder rate ranging from 15 to 40%, depending on the farm monitored. An average fertility index of 2.12 to 2.20. All the results obtained show a low production level on the monitored farms, likely explained in part by the nutritional imbalance in the rations distributed.

Keywords: Dairy cow, Diet, Reproduction, fertility, Body condition, Artificial Insemination,

Study of the effect of antibiotics and probiotics on sperm quality *in vitro* using an automated semen analysis system (CASA)

Kalem.Ammar[1*], Djallel Adel[1] , Daoudi Zerrouki.Nacira[2], Hadj Omar Karima[1],

[1]Laboratory of Biotechnology in Animal Reproduction (LBRA), Institute of Veterinary Sciences, University of Blida 1, Blida, Algeria
[2]Natural Resources Laboratory. Faculty of Biological Sciences and Agronomic Sciences. University of Tizi-Ouzou. Algeria.

Abstract

The experimental study focused on the effect of antibiotics and probiotics on sperm quality in vitro using an automated semen analysis (CASA) system. Previous studies have confirmed the harmful effects of antibiotics on sperm. Through our study, we aim to explore the use of probiotics as a biological alternative to antibiotics in the treatment of genital infections. We also aim to find synergy between certain non-toxic antibiotics and probiotics in order to broaden the spectrum of activity in certain therapeutic strategies. This work was carried out at the Animal Reproduction Biotechnology Laboratory (LBRA), located at the Blida 1 Veterinary Institute. To carry out our experiment, we chose for our first approach, the most widely used antibiotics in human medicine and in veterinary routine. To respect the minimum inhibitory dose, eight antibiotic discs were used during this study. These are tetracycline (TE 30), ciprofloxacin (Cip5), erythromycin (E5), rifampicin (Rif30), gentamycin (GN10), co-trimoxazole (CT10), colistin (Co10), amoxicillin and clavulanic acid (AMC30). Each antibiotic is Co incubated at 37°C for 4 hours, with frozen bovine semen from the artificial insemination and genetic improvement center (CNIAAG). For our second approach, we co-incubated the semen with a probiotic (lactobacilli) while respecting the minimum effective dose, which must be 106 CFU/g. The final step involves selecting the antibiotic that would be suitable for co-incubation with the probiotic. To do this, an antibiogram was developed using only non-toxic antibiotics, after inoculation with the lactobacilli. Our study confirmed the toxic effect of ATB on sperm, unlike probiotics, which demonstrated a significant improvement in all sperm cell parameters during co-incubation. We hope to use further studies to select antibiotics that would not have a toxic effect on sperm cells and to identify a likely antibiotic-probiotic combination.

Evaluation of corrosion inhibition effect of pyrimidine derivative on aluminium alloy by electrochemical techniques

Moussaoui Kamilia[1,*], Abderrahmane Sihem[1], Larkem Hamama[1], Abderrahim Karima[1] And Berrezag Kamel[1]

[1]Surface Engineering Laboratory (L.I.S), Department of chemistry, Faculty of Sciences, University BADJI Mokhtar –Annaba, B.P.12, Annaba 2300, Algeria

Abstract

In this work, two pyrimidine derivative molecules (2-amino-5,7-dimethyl-1,2,4-triazolo [1,5-a] pyrimidine (ADTP) and 2-amino-4,6-dimethyl pyrimidine (ADMP)) are used as effective inhibitors for aluminium alloys in 1 M HCl. The inhibitive performances are evaluated by electrochemical measurements and surface characterization. The results indicate that inhibition performances of ADTP and ADMP are closely related to the concentrations, influenced by the combination of steric hindrance and bonding effects. At relatively concentrations (10^{-2} – 10^{-5} M), ADTP displays a more pronounced ability to inhibit corrosion than ADMP, owing to more anchoring functional groups. The interaction between the Al electrode and ADTP results in the formation of a more condensed protective film than ADMP at low concentrations. Furthermore, the effect of temperature variation was investigated to gain deeper insight into the inhibition mechanism. Electrochemical tests performed at different temperatures revealed that inhibition efficiency decreases with increasing temperature, suggesting that physical adsorption plays a dominant role in the protective behavior. Thermodynamic parameters were also calculated to support this observation, highlighting the influence of thermal activation on the adsorption process of both inhibitors.

Abstract

Gum arabic (GA), also known as acacia gum, is a natural exudate obtained from the Acacia senegal and Acacia seyal trees and is one of the oldest and most widely used natural gums. It is a naturally high-viscosity natural polymer, and its quality is generally assessed by appearance, moisture content, viscosity, pH, and mineral profile, including Ca, Na, K, P, and various trace elements [1]. Structurally, GA is a branched polysaccharide composed of galactose, arabinose, rhamnose, and uronic acids. It has GRAS status [2] and is valued for its water solubility and functional properties, such as stabilization, emulsification, thickening, film formation, and encapsulation. Viscometery is a widely used technique for studying polymer behavior in dilute solutions and provides a simple means of assessing structural properties, polymer concentration, chain dimensions, molecular weight, and thermodynamic parameters. This study analyzed the effect of polymer concentration on the behavior of aqueous GA solutions. Viscosity, defined as the resistance to flow, results from the frictional interactions between the solute and solvent molecules [3]. Dynamic and kinematic viscosities were determined using a Hoppler KF 3.2 falling ball viscometer. Gum arabic solutions of different concentrations were prepared using double-distilled water as the solvent. Each solution was thoroughly mixed to ensure complete dissolution of the polymer before analysis. To ensure constant experimental conditions, all solutions were equilibrated at 25°C for 15 minutes before measurement. Determination of dynamic viscosity: The dynamic viscosity (η) of the GA solutions was calculated according to the following equation:

$$\eta = \boldsymbol{k}(\boldsymbol{\rho_1} - \boldsymbol{\rho_2})\boldsymbol{T}$$

where $\boldsymbol{k}$ is the instrument constant ($k = 0.07$), ρ_1 is the reference density ($2.22\ g/cm^3$), ρ_2 is the density of the GA solution at a given concentration, and T represents the measured drop time. T was recorded for each concentration. All measurements were performed in triplicate to ensure accuracy and reproducibility. Determination of kinematic viscosity: Kinematic viscosity (ϑ) was determined according to the following relationship:

$$\boldsymbol{\vartheta} = {}^{\eta}/_{\boldsymbol{\rho_2}}$$

Where η is the dynamic viscosity determined above and ρ_2 is the density of the solution in question.

Table 1.

Gum Arabic	2,5%	5%	10%
Dynamic Viscosity, $mPa \cdot s$	2.79	4.32	7.61
Kinematic Viscosity, $\frac{mm^2}{s}$	2.76	4.24	7.39

Based on experimental results, it was determined that the viscosity of gum arabic is highly dependent on concentration. Specifically, an increase in polymer concentration leads to a corresponding increase in viscosity [4]

Abstract

In the quest for innovative, high-performance materials suitable for antioxidant applications, density functional theory (DFT) was employed to design a new series of compounds derived from small, biodegradable organic molecules. The study involved grafting the negatively charged D-glucosamine (GleN) unit and various essential amino acids onto the 3 and 4′ carbon atoms of the trans-2,4,3′,5′-tetrahydroxystilbene (trans-OXY) backbone. This molecular modification aimed to prevent trans-OXY isomerization into its less stable cis form and to enhance its electronic and antioxidant properties. DFT calculations performed at the PW91/TZP level in aqueous phase revealed that the designed biomolecules (GleN-OXY-AA) displayed superior antioxidant performance compared to both free OXY units and essential amino acids, as reflected by their bond dissociation energy (BDE) values. Among them, GleN-OXY-Ile and GleN-OXY-Trp exhibited the lowest average BDE (66.355 kcal/mol), corresponding to 1.82 times the activity of trans-OXY and 1.55 times that of ascorbic acid (Vitamin C). Atoms-in-Molecules (AIM) analysis further demonstrated that these biomaterials favor the formation of quasi-cyclic structures through intramolecular H···O hydrogen bonding, which enhances π-electron delocalization and stabilizes radical, cationic, and anionic species. Quantum chemical descriptors indicated that hydrogen atom or electron release occurs at sites of lower electronegativity, as visualized by molecular electrostatic potential (MEP) maps and quantified by Hirshfeld atomic charge analysis.

ORAL PRESENTATION

Prevention of transmission and infection by Parvovirus B19, in children with Hemoglobinopathy, who receive blood transfusions.

Theodhor Disho*[1], Manika Kreka[2]

[1]Pediatrican, Social Health Centre no.2 Korçë, Albania

[2]Pediatric Department, Faculty of Medicine, University of Medicine, Tiranë, Albania

Abstract

Parvovirus B19 is a small, single-stranded DNA virus that infects erythroid progenitor cells. In patients with hemolytic anemia, such as children with hemoglobinopathy, Parvovirus B19 can cause aplastic crisis and put their health at serious risk. For this reason, although documented cases of parvovirus transmission through blood transfusion are rare, measures must be taken to detect potential cases in time and prevent them. A study conducted in Albania in 2025 showed that Parvovirus B19 is widely distributed in the general population, with approximately 35% prevalence in voluntary blood donors. Albania, like many other countries, does not include routine screening of all blood donors for Parvovirus B19. In addition, patients are not tested before and after transfusion for the presence of the virus. This indicates that children with hemoglobinopathy, who depend on regular blood transfusions, remain at risk of infection. These findings highlight the need to protect these patients from complications associated with parvovirus, given their reliance on transfusions. Specifically, our work focuses on measures that can be proposed and implemented in order to ensure the most comprehensive protection against parvovirus transmission. From our study, we conclude that the safest measure to prevent the transmission of Parvovirus B19 through blood transfusion in children with hemoglobinopathy is to introduce standard blood screening for Parvovirus B19 for all donors. This would provide full protection not only for at-risk groups but for the entire population. If it is not feasible to screen all blood donors, then blood intended for transfusion in children with hemoglobinopathies should, in addition to routine infectious disease screening, also be tested for Parvovirus B19. This would offer complete protection for these patients, although not for the general population. If neither of these can be integrated into standard protocols, we suggest that before transfusion, these patients be tested for the presence of IgG antibodies to Parvovirus B19. Children who already have antibodies are generally protected, and the likelihood of reinfection is very low. For this reason, we recommend that for children/patients without antibodies, the blood intended for transfusion be tested for parvovirus beforehand. This will significantly reduce the risk of infection for this group. The final measure—perhaps the safest and least costly in terms of both financial resources and long-term health consequences—would be the development of a Parvovirus B19 vaccine and its administration to all patients diagnosed with hemoglobinopathy, or at least those who require long-term blood transfusions. Although we currently lack the means to develop this vaccine, understanding its potential protective benefits leads us to call upon countries in the region and beyond, as well as researchers and scientists, to begin work on its creation. May this “small” call lead to a great result for the future.

Abstract

In this study, *Zygophillum album* L., a plant of medical importance, was for the first time, *in vitro* germinated, callus and plant regeneration was achieved. Protocols were developed for sterilization, *in vitro* seed germination, callus and shoot formation. Seed germination was affected by pre-soaking interval, sterilization strength, MS concentration, and incubation conditions. Among five treatments, seeds soaked for 48 h, sterilized with 70% ethanol + 4% NaOCl, and cultured on ¼ MS medium under initial darkness accomplished the highest germination rate of 83.9% with no contamination. Cotyledon, hypocotyl, root, and shoot tip explants excised from 12–14-day-old seedlings were cultured on various media. Pale green, compact callus formed from cotyledons and hypocotyls on ½ MS + 0.5 mg/L 2,4-D + 0.1 mg/L kinetin with 97% and 96% induction, respectively, whereas roots showed slower callus initiation, reaching 100%. Shoot tips on MS + 5 mg/L BAP + 1 mg/L NAA medium gave 55% shoots after one month with shoot elongation and leaf development. Subculturing enhanced shoot formation, achieving 100% on MS + 5 mg/L BAP + 1 mg/L NAA medium. Explants from 3–5-week-old seedlings (leaves, hypocotyls, shoot tips, and roots) were cultured on media supplemented with BAP, NAA, 2,4D or TDZ. Callus was initiated within 1–2 weeks, with hypocotyl explant exhibiting stronger callus growth on MS + 1 mg/L BAP + 0.5 mg/L NAA. Shoot tip explants attained up to 80% shoot formation on 1/2MS + 5 mg/L BAP + 1 mg/L NAA with average shoot length of 2.2 cm, while MS + 2.5mg/l TDZ + 0.5 NAA promoted succulent leaf growth with 60% shoot formation. Generally, this study highlights the importance of pre-soaking interval, sterilization strength, initial dark incubation, and proper media composition for efficient *in vitro* germination, callus induction, and shoot formation of *Zygophyllum album* L.

Keywords: *Zygophyllum album* L., *in vitro* germination, callus induction, shoot formation.

Abstract

This study aims to comprehensively reveal the multi-layered physiological and biochemical effects of water-soluble non-peripheral octa-substituted zinc phthalocyanine complexes (DE-C4-ON-ZnQ and DM-C4-ON-ZnQ) on Cucumis sativus seedlings grown under zinc deficiency conditions. [1]. The complexes, prepared at concentrations of 50%, 75%, and 100% to be equivalent to the Zn level in Hoagland solution, were applied with foliar formulations containing and not containing Tween-20, and the bioavailability, cellular response mechanisms, and stress modulation capacity of these new-generation Zn carriers were evaluated in detail [2]. Zn complexes significantly improved key physiological indicators of plant growth and development by markedly reducing Zn deficiency-specific morphological abnormalities and chlorotic leaf development. Applications with Tween-20 at 75% and 100% concentrations [3] significantly increased penetration from the leaf surface and systemic distribution; notable increases were recorded in the fresh/dry weight ratio, relative water content, and photosynthetic pigment stability. TBARS analyses showed that Zn-Pc complexes significantly reduced oxidative stress mediators by suppressing membrane lipid peroxidation, indicating the reactivation of zinc-dependent antioxidant pathways.

In the overall evaluation, both complexes were found to be effective as strong sources of Zn bioavailability; however, the DM-C4-ON-ZnQ compound demonstrated a superior activity profile compared to the DE derivative due to its superior performance in biomass accumulation, pigment stability, and membrane protection.

Abstract

The persistence of pesticides and other agrichemicals in food products causes both public health and economic problems. While strict regulations guide acceptable chemical residue limits to protect end consumers, there is an obvious need to develop field-deployable sensors for in-line chemical residue monitoring in the agricultural industry. Surface-Enhanced Raman Scattering (SERS) is a promising technique that offers chemical fingerprinting capabilities, alongside translational potential through miniaturizable components and easy integration into data processing workflows and automation for end-use with minimal expertise. This study reports the evaluation of a novel gold nanotriangle (NTA) metal–insulator–metal (MIM) metasurface for SERS detection of four common pesticides (Acetamiprid, Chlorpyrifos, Metalaxyl, and Tebuconazole) in Cucumber and Pepper samples. Emphasis was placed on reproducibility, sensitivity, and selectivity under realistic analytical conditions. The novel NTA-MIM substrate, featuring dual tip-to-tip and back-to-back configurations, was fabricated on top of an Al/SiO_2 stack using an optimized electron-beam lithography and thin-film deposition workflow. The substrate had previously demonstrated a ~10^6 enhancement factor and detection limits in the femtomolar (fM) range for thiophenol dyes. In this study, µM – nM limits were realized for the detection of pesticides in cucumber and pepper matrix media, based on univariate concentration analyses. In wild Tebuconazole-contaminated field-sourced samples confirmed by LC-MS assays, the substrate demonstrated selective detection of the chemical residue. Multivariate classification using an unsupervised PCA model also revealed sufficient variability in a three-component space, encoded by the spectra, which enabled the successful classification of chemical contaminants in field-sourced samples at levels beyond the detection limit. While further development is required to improve the system's sensitivity, miniaturization, and stability assessment for field deployment, the findings reported in this study clearly demonstrate its potential for reliable fingerprinting and detection of chemical contaminants in complex food matrices.

Abstract

Cryogels are highly porous polymeric materials with large surface area and absorption capacity. Cryogels having reactive groups make them attractive platforms for covalent bioimmobilization. While click chemistry is commonly used for polymer modification, catalyst-free reactions such as isocyanate–amine coupling enable efficient biomolecule conjugation under mild conditions. In this study, we synthesized cryogels with isocyanate functionality via photopolymerization of 2-isocyanoethyl methacrylate (ICEMA), poly(ethylene glycol) methyl ether methacrylate (PEGMEMA), and poly(ethylene glycol) diacrylate at –13 °C. By varying the monomer ratios, cryogels with different ratio of reactive isocyanate groups were obtained. Obtained materials were characterized by FTIR, TGA, SEM, and rheometry. Conjugation with 4-(trifluoromethyl)benzylamine, fluoresceinamine, and FITC-labeled bovine serum albumin confirmed direct immobilization of small molecules and proteins. The number of immobilized proteins could be tuned by changing the isocyanate content of the cryogel. These results demonstrate the potential of isocyanate-functionalized cryogels as effective platforms for biomedical and biotechnological applications.

Abstract

In this study, silver nanoparticles (AgNPs) were synthesized using *Lilium ciliatum* leaf extract obtained through supercritical CO_2 extraction (SFE-CO_2). In the green synthesis approach, plant materials utilize their biological extracts as reducing and capping agents, making the process highly economical because it significantly lowers the overall cost of synthesis (1). Leaves collected from Haçkalı Baba Plateau (Trabzon, Türkiye) was dried, mechanically fragmented, and subjected to SFE at 150 bar and 40 °C to obtain a phytochemically rich extract. Aqueous solutions of the extract at 2% (w/v) concentration were mixed in volumes of 0.1–6 mL with $AgNO_3$ solutions prepared in the range of 0.01–10 mM. The reaction mixtures were subjected to microwave irradiation at 90 W for 1–60 minutes, during which the appearance of a characteristic yellow color indicated the formation of silver nanoparticles. UV-Visible spectroscopy in the range of 300–800 nm was employed to confirm the synthesis of AgNPs by monitoring the surface plasmon resonance (SPR) bands characteristic of silver nanoparticles (2). This study demonstrates the potential of *Lilium ciliatum* leaf extract as a natural reducing and stabilizing agent in green nanoparticle synthesis and provides an effective microwave-assisted approach for the rapid and environmentally friendly production of AgNPs.

Abstract

In this century, drug consumption has become an indispensable part of healthcare. The emergence of new epidemics and disease types has led to the inadequacy of existing drugs and treatment methods. Furthermore, the unnecessary and incorrect use of antibiotics has led to the development of resistant bacteria, and the protective properties of existing antibiotics have diminished. This has led scientists to search for more effective and safer drugs. In our study, we achieved the biosynthesis of a novel CA-SeNP, not yet available in the literature, using an extract of endemic black chickpeas (*Cicer arietinum* L.) grown in the Mardin region. Thus, instead of using expensive and toxic chemicals, we achieved nanoparticle synthesis with a simple, rapid, inexpensive, and non-toxic, environmentally friendly, green approach. Furthermore, by incorporating polydopamine (PDA) with catechol groups into the synthesis procedure, we successfully synthesized SeNPL (PDA_SeNPL) decorated on the PDA surface. In this way, we aimed to increase the biological activity of the bionanomaterial by enabling a more controlled release of SeNPL from the PDA surface. The structure of this new drug precursor, not yet available in the literature, was elucidated using various characterization techniques. For this purpose, we utilized techniques such as FTIR, XRD, SEM, EDAX, TEM, UV-Vis, DLS, and Zeta Potential. The structures of these new bionanomaterials were thoroughly elucidated, and their various biological activities, including antioxidant, antibacterial, and antifungal, were tested in vitro.

Abstract

Alzheimer's disease (AD) is a neurodegenerative disease and the most common form of dementia, accounting for 60-80% of all dementia cases. Exercise has positive effects on emotional and cognitive performance during brain aging. Life kinetic exercises are a form of enjoyable mental exercise that advances the brain's working principles from simple concepts to complex and unique concepts. Melatonin is a hormone secreted by the pineal gland in the dark, under the control of the suprachiasmatic nucleus (SCN). It has a neuroprotective effect. In AD, melatonin levels decrease with disease progression. Melatonin deficiency is a sign of worsening AD. Cortisol is the main hormone associated with awakening, alertness, and the stress response. Cortisol levels are high in the early stages of AD. Cortisol and melatonin follow the circadian rhythm. Regulating these parameters in the preclinical stage can prevent AD. The effects of Life kinetic exercises were investigated in healthy individuals and patients with late-onset AD aged 65 and over. Participants performed Life kinetic exercises three times a week for 8 weeks. For analyses, blood samples were taken from participants before and after exercise. Plasma melatonin, cortisol levels, and Pittsburgh Sleep Quality Index (PSQI) were analyzed. Analysis results showed that Life kinetic exercise had no significant effect on PSQI, melatonin, or cortisol levels between the AD and control groups.

Keywords: Alzheimer’s disease, exercise, melatonin, cortisol.

Abstract

Pesticides are chemical agents widely used to boost agricultural yields and control insect infestations; however, their extensive and often unregulated use has raised significant concerns about food safety and environmental health. This highlights the need for strong ecological protection regulations. Early detection not only guarantees conformity with legal standards but also safeguards human health and agricultural systems through prompt preventive actions. This paper introduces the development of a MIM-SERS (Metal–Insulator–Metal Surface-Enhanced Raman Spectroscopy) platform integrated with artificial intelligence for straightforward and sensitive detection of pesticide residues in actual food samples. The engineered hexagonal MIM metasurface array ensures consistent Raman signal enhancement through durable plasmonic interactions and hotspot distribution. In cucumber samples, which serve as a representative food matrix, six distinct pesticide residues were analyzed. The intricate molecular structures of these compounds often lead to spectral overlaps and baseline variations, resulting in noise within the Raman spectra. All spectral data were meticulously preprocessed, incorporating Savitzky-Golay filtering, polynomial correction, and normalization—beyond mere smoothing. This preprocessing efficiently diminished noise and baseline drift, thereby enhancing both the identification and quantification precision. The Deep Feed-Forward (DFF) model effectively classified the six pesticide types with an accuracy exceeding 90%, and pesticide concentrations were additionally estimated for quantification purposes. The detection limits were below the regulatory thresholds, demonstrating the potential of the proposed MIM-SERS–AI platform as a scalable solution for real-time pesticide surveillance in the future.

Abstract

Psoriasis is a chronic autoimmune skin disease that causes skin cells to multiply faster than usual. Topical corticosteroids, methotrexate (MTX), and cyclosporine can be used to treat this disease. Drug delivery systems aim to minimize the problems that arise during drug administration and ensure more effective drug delivery to the target tissue. The goal of study is to develop a hydrogel form containing MTX nanocarrier composed of lipids to provide increased skin hydration and permeability, increased therapeutic, antioxidant, and wound-healing capacity, and reduced toxic effects of the system. In addition, the controlled drug release from the gel formulation supports prolonged drug penetration into the deeper layers of the skin during dermal applications, compared to release from nanoparticles alone. The nanostructured lipid carriers (NLCs) used in the project were synthesized using hot homogenization and ultrasonication methods. MTX was loaded into NLCs, and drug encapsulation was quantified by UV-Vis spectrophotometry at 300 nm. The drug delivery system was characterized using FTIR and SEM. The developed drug delivery system was transferred into carboxymethyl cellulose (CMC) hydrogel and optimized for topical applications. According to the data, MTX encapsulation was achieved with 76% efficiency, and encapsulation was confirmed by chemical analyses. The MTX was released from NLC in a controlled manner. The MTX-loaded NLC gel formulation was achieved at a suitable pH for the skin and the formulation maintained its spreadability. We suggest that the hydrogel formulation containing MTX-encapsulated NLC has promising potential for topical treatment of psoriasis.

Keywords: Psoriasis, methotrexate, nanostructured lipid carrier, carboxymethyl cellulose hydrogel, drug delivery.

Abstract

Health authorities report that the increase in pesticide use poses serious risks to the environment and human health. This situation further increases the need for effective methods to detect these residues. In this study, we propose a MIM-based Bowtie SERS nanoarray platform for the detection of three different pesticide classes (Pyrimethanil, Imidacloprid, Chlormequat Chloride). Spectra with high signal-to-noise ratios were collected using an in-house Raman spectroscopy device. The maximum residue limit (MRL) obtained for PYM in pepper juice (0.161 ppm) was found to be below the MRL value (2 mg/kg) reported by the EPA. This indicates that the chemical structure of PYM interacts effectively with the π-Au bond on the SERS surface. The concentration-dependent separation of pesticides and the separation of pepper juices from different regions were successfully and efficiently achieved using unsupervised machine learning algorithms. These findings underscore the potential of the proposed platform for the quick and straightforward detection of pesticide residues in pepper juice.

Keywords: Pyrimethanil, Imidacloprid, Chlormequat Chloride, Pepper, Bowtie Nanoarray, Surface-Enhanced Raman Spectroscopy (SERS).

Abstract

Macronutrient deficiencies such as nitrogen (N), phosphorus (P), and potassium (K) have detrimental effects on plant growth, productivity, and overall crop quality. Early and accurate detection of these deficiencies is essential for sustainable nutrient management and enhanced agricultural efficiency. In this study, a deep learning-based image analysis pipeline was developed to detect and classify nutrient deficiencies in 20 genotypes of Arabidopsis thaliana, a widely used model organism in plant research. High-resolution RGB images were captured under controlled growth conditions, and two main methodological frameworks were implemented: (1) feature extraction using pre-trained convolutional neural networks (CNNs) in combination with traditional machine learning classifiers, and (2) transfer learning approaches that fine-tuned existing deep learning architectures with structural optimization. Despite observable variations in phenotypic responses among genotypes, including differences in leaf color, morphology, and pigment accumulation, the models successfully identified nutrient deficiencies with high precision. Individually, deep learning models achieved an average classification accuracy of 98.96%, while an ensemble model integrating multiple architectures reached perfect accuracy (100%). The proposed approach offers a non-invasive, cost-effective, and scalable solution, providing a significant advantage over conventional laboratory-based diagnostic techniques. By enabling the timely detection of nutrient stress, this study contributes to the advancement of precision agriculture. It supports the integration of AI technologies into smart farming systems, thereby improving decision-making and resource efficiency.

Abstract

The rise in global demand, coupled with growing environmental concerns, necessitates the identification of new energy sources that can support socioeconomic development while minimizing pollutant emissions. Aquatic biomasses, particularly invasive aquatic macrophytes, may serve as viable bioeconomic resources. This study seasonally evaluated the nutrient composition, elemental content, essential and nonessential metal contents, and overall characterization of the invasive macroalga *Stypopodium schimperi* to assess its potential as a value-added biomass and bioeconomic resource. Regarding the Fourier-transform infrared spectroscopy (FT-IR) analysis, various characteristic peaks were observed over a wide wavelength range in the IR spectrum. Examination of the main peaks revealed broad and strong bands in the range of 3500–3200 cm^{-1}, indicating that the invasive alien macroalga *S. schimperi* contains numerous organic molecules such as polysaccharides, proteins, lipids, and phenolic compounds. The present study showed that the invasive macroalga *S. schimperi* represents a rich biomass source of essential metals such as Ca, Mg, Ni, Zn, Cu, and Fe. In addition, the detection of only low quantities of toxic or nonessential metals (Pb, Cd, Hg) suggests its potential safety for use in the food industry or biotechnological applications. The elemental composition of *S. schimperi* collected during the summer season was determined to be 35.633 ± 0.511% C, 5.137 ± 0.160% H, 1.581 ± 0.204% N, 0.411 ± 0.047% S, and 57.238 ± 0.568% O. For samples collected in the autumn season, the elemental composition was 35.283 ± 0.493% C, 5.083 ± 0.256% H, 1.507 ± 0.260% N, 0.446 ± 0.058% S, and 57.681 ± 0.500% O, indicating that this biomass could be utilized as a renewable energy source, such as for producing biofuel or biochar, within the framework of the Blue economy. Furthermore, this study generally observed that *S. schimperi* has moderate levels of protein and carbohydrates, low levels of lipids, and high moisture content in terms of nutritional composition, suggesting that this species could be used as a raw material in functional foods, feed additives, or biotechnological applications.

Abstract

Algae's capacity to accumulate metals and reduce metal ions renders them an exceptional candidate for nanoparticle biosynthesis, thereby earning them the designation of bio-nano factories. The aim of the study was to synthesize novel gold nanoparticles (AuNPs) from invasive brown macroalga *Stypopodium schimperi* aqueous extract and, analyze acute and sub-acute toxicity of biogenic gold nanoparticles (AuNPs) to a model organism *Daphnia magna*. The characterization of biogenic AuNPs had been conducted using multiple instruments including transmission electron microscopy (TEM) and zeta potential assessment. Bioassays for the determination of acute and subacute toxicity of algal derived Biogenic AuNPs were performed according to OECD 202 (OECD, 2009) guidelines for 96-hour and 21 days, respectively. The LC_{50} value at 96 hours, with 95% confidence, was determined to be 2.3 mg L^{-1} for *S.schimperi*@AuNPs. Based on these genotoxicity and cytotoxicity results, these can be said that the 0.25 ppm concentration of Biogenic AuNPs derived from *S. schimperi* is not genotoxic, while the 0.5 and 1.0 ppm concentrations cause minimal DNA damage (approximately 3% and 7%) and have low genotoxicity. Also, the cell viability at biogenic AuNP concentrations of 0.25, 0.5, and 1.0 ppm was 93.3%, 86.7%, 73.3%, and 70.0%. Biogenic AuNPs from *S. schimperi* at subacute doses were not harmful according to ISO 10993-5. This study has shown that both the environmentally friendly synthesis procedure of AuNPs can be safely used for future industrial and therapeutic needs, and that it can serve as a basis for innovative approaches to the use of invasive algae in safe nanotechnology.

Abstract

In this study, ternary nanocomposite fibers were produced using two different layered nanomaterials. First, a TiO_2 solution was prepared by the sol-gel method. Reduced graphene oxide (rGO) and hexagonal boron nitride (h-BN) were then added to this solution in different ratios to obtain a ternary mixture. Using this solution, ternary nanocomposite fibers were fabricated through electrospinning. The structural and surface characteristics of the nanofibers were confirmed by XRD, FTIR, Raman, FESEM, and EDX analyses. Due to their large surface area, the nanofibers have significant potential for use in photoanodes of dye-sensitized and quantum dot-sensitized solar cells.

Abstract

In this study, h-BN was first incorporated into a TiO_2 solution, and the resulting mixture was used to directly deposit TiO_2/h-BN photoanodes onto FTO substrates via electrospinning. The surfaces of the fabricated photoanodes were then coated with CdSe quantum dots using the SILAR technique. Quantum dot-sensitized solar cells were assembled by filling a liquid electrolyte between the prepared photoanodes and a Pt counter electrode. The electrical characteristics of the fabricated solar cells were measured using a solar simulator. An improvement in efficiency was observed compared to the pure TiO_2-based cell.

Regulatory role of caveolin-1 in doxorubicin-induced SASP and its impact on cancer cell proliferation

Yaprak Dilber Şimay Demir, Kader Yılmaz*

Gazi University, Faculty of Pharmacy, Department of Pharmacology, Ankara, Türkiye

*Corresponding author e-mail: yilmazkadeer@gmail.com

Abstract

Cellular senescence is characterized by an irreversible arrest of cell proliferation induced by various stressors, including telomere shortening, DNA damage and chemotherapeutic agents. Senescent cells develop a distinct secretory phenotype termed the senescence-associated secretory phenotype (SASP), which actively modulates the surrounding microenvironment. Under physiological conditions, SASP contributes to the immune-mediated clearance of senescent cells; however, insufficient elimination can lead to a highly pro-inflammatory microenvironment that facilitates tumor initiation and progression. Compounds capable of modulating SASP secretion are referred to as senomorphic agents and the identification of such molecules offers promising opportunities for therapeutic innovation in oncology. Previous studies have shown that caveolin-1 expression is increased in senescent cells induced by oxidative stress, UV-C radiation, bleomycin, or oncogenic K-Ras, and that caveolin-1 may be important in the developmental processes of senescence. However, no study has been encountered in the literature directly evaluating the effectiveness of Caveolin-1 on chemotherapeutic-induced SASP. In this study, we investigated whether Caveolin-1 knockdown in doxorubicin-induced senescent A549 and HeLa cancer cells could alter SASP production and influence the proliferation of neighboring non-senescent cells, assessed using the xCELLigence real-time cell analysis platform. Our findings indicate that SASP derived from Caveolin-1–suppressed senescent A549 cells did not affect the proliferation of non-senescent A549 cells. In contrast, SASP from Caveolin-1–suppressed senescent HeLa cells significantly reduced the proliferation of non-senescent HeLa cells. These results suggest that Caveolin-1 may represent a promising senomorphic target, particularly in the context of cervical cancer. Further research is warranted to elucidate the underlying mechanisms and to explore the translational potential of Caveolin-1–modulating strategies in contemporary cancer therapeutics.

Abstract

Alzheimer's Disease (AD) is a neurodegenerative disease characterized by progressive memory loss affecting the elderly population. Disruption of the biological clock increases the risk of developing AD, which in turn exacerbates circadian rhythm disorders. Whether disturbances in sleep and circadian rhythms cause AD, or AD causes sleep and circadian rhythm disorders, is largely unclear. Exercise is an important approach to maintaining or improving physical and mental health, including the brain. Exercise has positive effects on emotional and cognitive performance during brain aging. Life kinetic exercises are a form of exercise that involves enjoyable mental exercises that advance the brain's working principles from simple concepts to complex and unique concepts. The effects of Life kinetic exercises were investigated in healthy individuals and patients with late-onset AD aged 65 and over. Participants performed Life kinetic exercises three times a week for 8 weeks. For analyses, blood samples were taken from participants before and after exercise. Plasma protein levels of brain and muscle Arnt-like protein-1 (BMAL1) and circadian locomotor output cycles kaput (CLOCK), which are transcriptional activators of circadian rhythm, were analyzed by the ELISA method. Results showed no significant difference between the AD and control groups before and after exercise. However, BMAL1 levels increased in both groups after the Life Kinetic exercise, while CLOCK levels remained unchanged.

Keywords: Alzheimer's disease, circadian rhythm, exercise, BMAL1, CLOCK, ELISA.

Abstract

Fertilization success in olive production largely depends on pollen viability and tube growth, while low-temperature stress can impair these processes and reduce yield. This study examined the physiological and biochemical responses of five olive cultivars (Ayvalık, Erkence, Gemlik, Hayat, Memecik) to low temperatures (15, 10, 5 ºC) using pollen grains. Pollen germination rates and tube lengths were assessed. In Ayvalık and Hayat, both declined at 15 and 10 ºC, while in Erkence reductions occurred only at 15 ºC; at lower temperatures germination was absent, preventing tube measurement. In Gemlik, all treatments reduced both parameters, whereas in Memecik germination declined only at 10 and 5 ºC, with tube length unaffected. Groups without germination were excluded from further analyses. Antioxidant responses varied among cultivars. Superoxide dismutase activity decreased in Ayvalık (15, 10 ºC) and Erkence (15 ºC), increased in all Gemlik treatments, rose only at 10 ºC in Hayat, and declined under all Memecik treatments. Catalase activity decreased in Ayvalık (15 ºC) and Gemlik (all treatments) but remained unchanged in Erkence, Hayat, and Memecik. Ascorbate peroxidase activity decreased only in Ayvalık (15, 10 ºC). No significant differences were observed in antioxidant activity. Total phenolic content decreased in Ayvalık (15 ºC) and Memecik (10 ºC), but not in the other cultivars. Total flavonoid content increased in Ayvalık (15, 10 ºC), Erkence and Memecik (15 ºC), and Hayat (10 ºC), but decreased in Gemlik under all treatments. Overall, low-temperature stress produced cultivar-specific effects on pollen physiology and antioxidant defense, underscoring the importance of cultivar selection in breeding programs for climate change resilience.

Keywords: Antioxidant activity, Flavonoid content, Low-temperature stress, Phenolic content, Pollen germination, Pollen tube

Abstract

The present study aimed to investigate the essential oil composition of *Lathyrus laxiflorus* subsp. *laxiflorus* using gas chromatography coupled with mass spectrometry and flame ionization detection (GC-MS/FID). Essential oil was obtained through hydrodistillation and analyzed under optimized chromatographic conditions. The yield of essential oil was calculated as 0.22% (w/w, moisture-free basis). A total of 27 volatile compounds were identified, representing 96.86% of the total composition. The chemical profile was dominated by monoterpenoids (69.49%) and monoterpene (27.03%), with minor contributions from sesquiterpenes (0.14%) and sesquiterpenoids (0.20%). Camphor (44.60%) was determined as the major constituent, followed by borneol (8.32%) and 1,8-cineole (7.94%). Other components such as α-pinene, β-pinene, and camphene were detected in lower proportions. These results provide the first detailed report on the volatile composition of *L. laxiflorus* essential oil analyzed via GC-MS/FID. The predominance of camphor and related oxygenated monoterpenes indicates potential applications of this species in pharmaceutical and aromatic industries. This study highlights the chemotaxonomic relevance of *L. laxiflorus* and contributes to expanding the phytochemical knowledge of the genus Lathyrus.

Abstract

Lung cancer has the highest mortality rate among all cancer types and is usually diagnosed at an advanced stage. It is more common in elderly individuals and is difficult to treat because of its high malignancy and metastatic tendency. Therefore, in recent years, alternative therapeutic approaches have been developed for its treatment. Drug delivery systems can be potential solutions by enabling controlled release and reducing the side effects of chemotherapeutic agents. In this study, an inhalable drug delivery system was developed for the treatment of lung cancer. Doxorubicin (Dox), a chemotherapeutic agent, and caffeic acid (CA), a phytochemical compound, were used in combination within the polymeric nanoparticles. Caffeic acid has the potential to reduce the toxic effects of Dox while enhancing its anticancer activity. The carrier structure was synthesized using two natural polymers suitable for lung targeting: chitosan (CH) and carrageenan (CRG). Initially, caffeic acid and chitosan were covalently linked and caffeic acid/chitosan grafting ratio was found to be as 17.4%. Then, a CH/CA/CRG structure was formed through polyelectrolyte complexation between carrageenan and chitosan, followed by nanoparticle synthesis using cross-linking agents. Dox was encapsulated into the system and the highest encapsulation efficiency was found to be as 47.95% by spectrophotometrically. The obtained nanoparticles were characterized using Fourier Transform Infrared Spectroscopy (FT-IR) and Scanning Electron Microscopy (SEM). The nanoparticles were observed to be approximately 50 nm in size by SEM. In vitro drug release studies showed that release at pH 5.5 was higher than at pH 7.4. The developed nanoparticles could have a promising potential for future studies in targeted inhaler lung cancer treatment.

Keywords: Lung Cancer, Inhaler Drug Delivery, Caffeic Acid, Doxorubicin, Chitosan/Carrageenan Nanoparticles.

Abstract

In food packaging applications, petroleum-based polymers are widely used in the industry; however, their long-term persistence and resistance to degradation pose a significant threat to the environment. Moreover, the limited availability of petroleum resources has prompted an increasing demand for sustainable polymer alternatives. Consequently, interest in biodegradable and bio-based polymers has grown rapidly in recent years. In this study, poly(3-hydroxybutyrate-co-4-hydroxybutyrate) (PHB), which is both bio-based and biodegradable, was used to evaluate its potential as a sustainable alternative to synthetic polymers. To improve the properties of PHB film, fennel (F) and geranium (G) essential oils were incorporated at different concentrations (5-10-15-20 wt%). The PHB/F and PHB/G films were prepared via solution casting method. Manufactured films were characterized to determine their morphology, chemical structure, antioxidant and antibacterial activities, water vapor permeability, and biodegradability in soil. According to the FTIR results, no chemical reaction occurred between PHB and the essential oils. The antioxidant test results indicated that the DPPH radical scavenging activities of the films containing essential oils were 1–6% higher than that of the neat PHB film. The antibacterial activity test results showed that both essential oil–loaded films exhibited a strong inhibitory effect against *S. aureus*. In contrast, no significant antibacterial activity was observed against *E. coli*, indicating that the films were ineffective on this Gram-negative strain. Water vapor permeability of PHB slightly increased after the addition of essential oils. The films were buried in garden soil for 45 days, and their mass losses were measured. After 45 days, the neat PHB film exhibited approximately 20% mass loss, whereas the incorporation of essential oils significantly enhanced the biodegradability of the films. The highest mass losses were observed in the 5F and 5G films, with values of about 80% and 96%, respectively. The findings support the applicability of the produced essential oil-loaded films in the packaging industry.

Keywords: Active packaging, Biodegradable, Biobased, Essential oil, Poly (hydroxybutyrate)

Abstract

Nanoparticles are structures with sizes ranging from 1 to 100 nm, exhibiting unique properties distinct from macroscopic materials. Due to their high surface area-to-volume ratios, they behave much more effectively in chemical reactions. As their size decreases, their optical, electronic, and catalytic properties change significantly, making them extremely valuable in various applications. Nanoparticles can be metallic in structure (e.g., AgNP and AuNP) or exist in the form of metal oxides (such as TiO_2 and ZnO). Additionally, quantum dots exhibiting semiconducting properties and polymeric or lipid-based nanoparticles constitute another important class. These different types are extensively used, particularly in fields such as medicine, electronics, and catalysis. The advantages offered by nanoparticles in energy storage and environmental improvement applications are also increasingly recognized (Khan & Hossain, 2022; Jamkhande et al., 2019). Among nanoparticle synthesis methods, green synthesis offers an eco-friendly, non-toxic, and biocompatible approach, providing an alternative to traditional chemical methods. This method is also highly advantageous for industrial production due to its low cost and easy scalability. Phytochemicals such as flavonoids, polyphenols, alkaloids, and terpenoids obtained from plants act as powerful biological reduction agents. In addition, fungi, bacteria, and marine-derived polysaccharides and proteins are also among the effective biomolecules in nanoparticle synthesis. Therefore, green synthesis is an important method shaping the future of sustainable nanoparticle production (Malik et al., 2023). *Eucalyptus globulus* is a shrubby plant or flowering tree belonging to the Myrtaceae family. It is currently grown in many regions of the world. The leaves of the plant are rich in tannins, flavonoids, and phenolic acids, as well as volatile oils containing mainly eucalyptol (1,8-cineole) (Shala & Gururani, 2021). In this study, ZnO-NPs were synthesized via green synthesis using an extract obtained from *Eucalyptus globulus* leaves. In this context, the effect of temperature, pH, synthesis time, and reducing agent concentration, on the structure and character of ZnO-NPs, were determined. The synthesized NPs were characterized using UV-Vis spectroscopy, SEM, ATR-FTIR and XRD, and their antimicrobial activity against *E. coli*, *S. aureus*, *K. pneumoniae*, and *C. albicans* microorganisms were investigated.

Abstract

This study investigated the *in vitro* antidiabetic and antioxidant properties of three radish varieties—white radish (FBT), red radish (FKT), and black radish (FST)—sourced from Konya. . The evaluation encompassed several key biological activities. Total flavonoid content (TFC) and total phenolic content (TPC) were measured to establish the phytochemical composition. Antioxidant capacity was comprehensively assessed using the 2,2-diphenyl-1-picrylhydrazyl (DPPH), 2,2′-azino-bis(3-ethylbenzothiazoline-6-sulfonic acid) (ABTS), and iron chelation activity (FCA) assays. Antidiabetic activity was determined by quantifying the inhibition of the α-amylase and α-glucosidase enzymes. All absorbance readings were obtained utilizing an ELISA plate reader, and statistical data analysis was performed with Microsoft Excel and GraphPad software. Among the samples, red radish (FKT) exhibited the highest TFC (1.27 mg KE/g) and TPC (55.36 mg GAE/g), followed by black radish (FST) and white radish (FBT). Antioxidant activity, assessed via DPPH, ABTS, and iron chelation assays, revealed that FST had the strongest DPPH radical scavenging activity (84.32%; IC_{50} = 636.6 µg/mL), while FKT showed superior ABTS inhibition (83.79%; IC_{50} = 144.5 µg/mL) and iron chelation capacity (74.04%; IC_{50} = 677.2 µg/mL). In terms of antidiabetic potential, FKT demonstrated the most potent α-amylase inhibition (97.36%; IC_{50} = 2.07 mg/mL) and α-glucosidase inhibition (84.18%), indicating strong enzyme inhibitory activity. FBT showed moderate activity across most assays, while FST displayed notable antioxidant properties but comparatively lower antidiabetic effects. In conclusion, red radish (FKT) emerged as the most promising candidate among the three varieties, exhibiting the highest levels of bioactive compounds and the strongest antidiabetic and antioxidant activities. These findings suggest that FKT may offer valuable health benefits and could be further explored for its therapeutic potential in managing oxidative stress and diabetes-related conditions.

Abstract

Anabolic-androgenic steroids (AASs) are a large group of molecules that include endogenously produced androgens such as testosterone, as well as synthetically produced derivatives. They are widely used for aesthetic purposes, as they promote muscle growth, or for athletes seeking to enhance athletic performance. Despite their popularity, these substances are classified as prohibited substances because they can produce serious adverse effects. However, they are used at pharmacological doses to support the treatment of various diseases under physician supervision. However, the abuse doses of these substances are far higher than these pharmacological doses. AASs cause serious harmful effects on the heart, liver, brain, male and female reproductive systems, the endocrine system, and the immune system. While case reports demonstrating toxic effects on the pancreas exist in the literature, the molecular mechanisms involved in pancreatic toxicity remain unclear. It is known that disruptions in the regulation of apoptosis, a key molecular pathway in cells, play a significant role in pancreatic pathophysiology. There are no studies demonstrating the effects of AASs on the molecular pathway of apoptosis in pancreatic cells. This study aims to demonstrate the pancreatic toxicity of Nandrolone decanoate (ND), a widely abused AAS, and its effects on pancreatic apoptosis mechanisms in vitro using the PANC-1 cell line. In this study, inhibitory Concentration 50(IC50) values calculated as 62.8 µg/mL with MTT test. According to gene expression results, apoptosis related genes as P53, Bcl-2, Bax, Nf-kB, TNF-alpha, Jnk, miR-21, PI3-K, Akt, caspase-8, and caspase-9 levels were determined elevated for 24h ND exposure.

Keywords: Nandrolone decanoate, Pancreas, Apoptosis, miR21

Abstract

Cyclooxygenase-2 (COX-2) is an inducible isoform of the cyclooxygenase enzyme responsible for the conversion of arachidonic acid into prostaglandins, which regulate inflammation, pain, and cell proliferation. Overexpression of COX-2 has been associated with various cancers, including colorectal, breast, and lung cancers, due to its role in promoting angiogenesis, inhibiting apoptosis, and enhancing tumor growth. Therefore, selective COX-2 inhibition represents an important therapeutic approach not only for inflammation but also for cancer prevention and treatment. Hydrazone structure constitutes a special subgroup of Schiff bases and contains a C=N bond characterized by two different nitrogen atoms bonded together. Furthermore, considering the unshared electron pairs on the nitrogen atoms, the physical and chemical properties of hydrazones appear to be directly related to these groups. Because both nitrogen atoms in the hydrazone structure are nucleophilic, they are susceptible to electrophilic interactions, while the carbon atom can exhibit both nucleophilic and electrophilic characteristics. Hydrazones represent an important class of compounds in medicinal chemistry due to their versatile biological activities, including antimicrobial, anti-inflammatory, and anticancer properties. In particular, numerous studies in the literature have reported hydrazone derivatives as potent COX-2 inhibitors, underscoring their pharmacological relevance. In this study, a series of bis-hydrazone derivatives were synthesized and characterized by infrared (IR) spectroscopy, nuclear magnetic resonance (^{1}H-NMR and ^{13}C-NMR) spectroscopy. The synthesized compounds were further investigated through *in silico* molecular docking studies against the COX-2 enzyme (PDB ID: 3LN1). Docking results indicated that the bis-hydrazone compounds successfully occupied the COX-2 binding pocket and exhibited favorable binding energies, suggesting their potential as promising COX-2 inhibitors with possible anti-inflammatory and anticancer activity.

Abstract

Resveratrol, a naturally occurring polyphenolic compound, is widely recognized for its health-promoting properties. In this study, the resveratrol content of fresh grapes and grape pomace was determined using HPLC with external standard calibration. The calibration curve exhibited excellent linearity ($Y = 1.98582 \times 10^{-5}X - 0.3297$, $R^2 = 0.9997$, $R = 0.9998$), confirming the reliability of the method. Chromatographic analysis revealed a sharp peak at a retention time of 1.528 min for fresh *V. labrusca* samples, corresponding to a concentration of 282.6 ppm resveratrol (99.88% area). In *V. labrusca* pomace, resveratrol was also detected at a similar retention time (1.531 min), but with a lower concentration of 89.0 ppm (99.62% area). These results indicate that while fresh *V. labrusca* are a richer source of resveratrol, *V. labrusca* pomace still retains a substantial and noteworthy concentration of this bioactive compound. Rather than being treated merely as an industrial waste, *V. labrusca* pomace should be considered a sustainable and economically valuable reservoir of resveratrol, offering opportunities for high-value utilization. Its incorporation into nutraceutical, cosmetic, and pharmaceutical applications could not only enhance product functionality but also contribute to circular economy practices and environmental sustainability.

Abstract

Type 2 diabetes mellitus (T2DM), developing because of insulin resistance in peripheral tissues due to pancreatic β-cell dysfunction, a chronic metabolic disorder characterized by persistent hyperglycemia. This pathological state is associated with the impairment of insulin signaling cascades, along with metabolic stress imposed on glucocorticoid and GLP-1 receptors and the perturbation of glucose homeostasis. In this study, the interaction potential of the carotenoid pigment zeaxanthin, extracted from natural origins such as microalgae, on insulin, glucocorticoid, and GLP-1 target receptors associated with T2DM was evaluated by employing *in silico* molecular modeling approaches. Zeaxanthin binding affinities for selected glucocorticoid receptors (GR, PDB ID: 7LCJ), insulin receptors (INSR, PDB ID: 3ETA), and GLP-1 receptors (GLP-1R, PDB ID: 4LSJ) were computed using the molecular docking method, in comparison with structurally similar natural bioactive compounds and synthetic inhibitors. Molecular dynamics simulations were performed to assess the structural stability of the receptor–ligand complexes that achieved the best conformation over time. Additionally, RMSF, Rg, adsorption free energy (ΔG), and ADMET profiling evaluations were conducted. Zeaxanthin demonstrated binding energies of -9.9, -8.4 and -7.5 kcal/mol in the INSR, GR, and GLP1, respectively. Similarly, the binding affinities of other ligands structurally analogous to zeaxanthin were comparable to synthetic inhibitors and exhibited stronger binding interactions, supporting zeaxanthin's biological potential. Literature reports that zeaxanthin reduces insulin resistance through activation of the PIK3/Akt pathway indicate parallelism with the results of our study. Our findings highlight the potential of natural zeaxanthin as a versatile, targeted natural agent for alternative therapeutic strategies in chronic T2DM. In parallel with the findings demonstrating the potential of zeaxanthin to reduce insulin resistance within the scope of this study, our preliminary results identify zeaxanthin as a powerful therapeutic candidate of multi-targeted natural origin that enhances insulin sensitivity and modulates glucose homeostasis in alternative therapeutic strategies in T2DM.

Keywords: Zeaxanthin, T2DM, microalgae, natural therapeutic agent, treatment, molecular modelling.

Abstract

Polyolefins such as polyethylene and polypropylene are widely used in packaging and automotive industries; however, high melt viscosity and surface defects (melt fracture, sharkskin) limit processing efficiency. Conventional fluoropolymer-based processing aids effectively eliminate these problems but raise serious environmental and health concerns due to persistent per- and polyfluoroalkyl substances (PFAS). In this study, a novel PFAS-free multifunctional processing aid was developed by functionalizing hexagonal boron nitride (hBN) with 3,5-di-tert-butyl-4-hydroxybenzaldehyde (BHT-CHO) via urea and boric acid pyrolysis followed by solvothermal grafting. The synthesized hBN/BHT-CHO hybrid combines the lubricating and thermally conductive properties of hBN with the antioxidant activity of the hindered phenol derivative. Successful functionalization was confirmed by FTIR (new peaks at 3400 cm^{-1} ν(O-H) and 1710 cm^{-1} ν(C=O), TGA (~20 wt% organic loading, stability >260 °C), SEM (coated platelets 1–5 µm), and XRD (preserved hBN crystallinity). The developed hybrid offers dual functionality; flow enhancement and oxidative stabilization; making it a sustainable alternative for high speed extrusion of polyolefin films and pipes.

Keywords: hBN, polyolefin, processing aid, boron nitride.

Abstract

Melanoma is one of the most aggressive types of skin cancer, with its increasing incidence being linked to elevated exposure to ultraviolet (UV) radiation. Due to the limited efficacy of current therapies, there is a need to explore novel natural therapeutic agents. This study investigated the biological effects of 2-cyclopenten-1-one (2-CP), a naturally occurring compound found in Arum dioscoridis, were investigated on the human melanoma cell line (SK-MEL-30) and the healthy fibroblast cell line (L929). The cytotoxic and antiproliferative properties of the compound were evaluated using MTT and colony formation assays. Changes in the expression of TGF-β protein were analysed using Western blot. The findings revealed that 2-cyclopenten-1-one had a dose-dependent cytotoxic effect, demonstrating approximately 3-fold the toxicity of melanoma cells compared to healthy fibroblasts. (IC_{50}: SK-MEL-30, 58.8 µM; L929, 156.6 µM). Furthermore, the compound reduced colony formation by 76% and completely suppressed proliferation at a concentration of 100 µM. Western blot analysis revealed that LPS treatment increased TGF-β expression by approximately 1.5-fold. In contrast, 2-cyclopenten-1-one reduced this increase, restoring expression levels to near-baseline levels. These results suggest that the compound may have anti-tumour effects by inhibiting TGF-β-mediated proliferative signalling pathways. In conclusion, 2-cyclopenten-1-one emerges as a potential natural therapeutic agent with selective cytotoxicity against melanoma cells and a low toxicity profile. Further in vitro and in vivo investigations are needed to elucidate the compound's anticancer and immunomodulatory mechanisms.

Keywords: 2-cyclopenten-1-one, Anti-cancer effect, Anti-inflammatory effect, Arum dioscoridis, Melanoma

Abstract
Increasing soil salinity as a result of global climate change is one of the major abiotic stress factors limiting agricultural productivity. High salinity leads to growth retardation, yield loss, physiological disturbances, and various morphological abnormalities in plants. To mitigate the adverse effects of salt stress, the use of plant growth-promoting rhizobacteria (PGPR) has emerged as an important biotechnological approach in recent years. Halophilic PGPR can enhance plant tolerance to salinity due to their ability to survive and function under high salt concentrations. In this study, four different halophilic bacterial isolates with known plant growth-promoting (PGP) properties [*Bacillus atrophaeus* (EK3), *Promicromonospora* sp. (EM8), *Zhihengliuella salsuginis* (EM30), and *Thalassobacillus devorans* (EM34)] were applied to *Solanum lycopersicum* L. cv. Batem Özçelik F1 grown under different NaCI concentrations (0, 50, 100, 150 mM). Their effects on various growth parameters were evaluated. Plants were cultivated under controlled conditions for 45 days, and morphological characteristics such as leaf, root, and whole plant fresh weight (g), stem length (cm), root length (cm), leaf area (m^2), number of leaves, stem diameter (mm), and plant height (cm) were measured. The results showed that *B. atrophaeus* (EK3) significantly promoted plant growth under non-saline conditions. *Z. salsuginis* (EM30) increased stem length under moderate salinity, while *Promicromonospora* sp. (EM8) enhanced leaf number under 100 mM NaCl. In contrast, *T. devorans* (EM34) restricted plant growth under high salt conditions. Overall, these findings highlight the promising biotechnological potential of halophilic PGPR in improving salt stress tolerance in tomato plants, although the extent of this effect is contingent upon both the specific bacterial species and salt concentration. These insights provide a foundation for future research and practical applications in sustainable agriculture.

Keywords: Halophilic bacteria, tomato (*Solanum lycopersicum* L.), salt stress, PGPR, plant growth parameters.

Abstract

Glyphosate (Gly), as one of the herbicides, provides significant benefits in increasing agricultural and industrial production. The widespread use of any pesticide has led to environmental pollution, which is an important topic for current research [1]. Although it reduces the effects of weeds and pests [2], exposure to Gly can cause permanent damage to human health [3]. Therefore, the determination of Gly is important for environmental monitoring and reducing public health risks. Many expensive and time-consuming instrumental analysis methods requiring experienced personnel have been proposed. In recent years, the preparation of pesticide sensors using molecular imprinting technology has become prominent while offering advantages such as high sensitivity and selectivity, ease of use, rapid response time, and low cost [4,5]. Since molecularly imprinted polymer-based Gly sensors are relatively rare, this study aimed to prepare one for Gly determination with an aspect of adding nanomaterial. Electrochemical synthesis in the presence/absence of nanomaterials was performed by cyclic voltammetry on the Pt plate electrode at pH 5.0 PBS buffer media containing $LiClO_4$ as supporting electrolyte in a potential range of -0.1- +1.4 V with a scan rate of 50 mV/s. The effect of nanomaterials on the analytical performance of Gly imprinted polypyrrole films was investigated. The selectivity of the electrode was tested in the presence of similar structured pesticides, and it was observed that the electrode was highly selective to Gly. The linear working range of 0,5 aM- 0,26 fM and LOD of 0,002 aM were obtained by using differential pulse voltammetry. Finally, standard addition method was applied to ensure the successful utilization of proposed sensor in the determination of Gly in tap water and tomato juice samples.

Özet

Kâğıt gibi gözenekli yüzeylerde bulunan parmak izleri gizli parmak izleridir ve çıplak gözle görülmezler. Olay yerlerinde toplanan mektup ve fatura gibi pek çok önemli delildeki gizli parmak izlerinin görünür hale getirilmesi adli soruşturmalarda son derece önemlidir. Amino asitler parmak izi sıvısının önemli bir bileşenidir ve gözenekli yüzeylerde uzun süre kalabilirler. Bu nedenle gizli parmak izlerinin görünür hale getirilmesinde parmak izi reaktiflerinin amino asitleri hedef aldığı yöntemler sıklıkla kullanılmaktadır. Amino asitlerle reaksiyon neticesinde renkli veya lüminesans özellikte ürün oluşumuyla parmak izleri görünür hale gelir ve bu sayede kimlik tespitine imkân sağlanır. Gizli parmak izlerini görünür hale getirmek için sınırlı sayıdaki reaktif aktif olarak kullanılmaktadır. Bu reaktiflerden ninhidrin ve 1,2-indandion kullanıcıda cilt ve göz tahrişine neden olabilir ve 1,8-diazafluoren-9-on ise çok pahalıdır. Bu nedenle bu reaktiflere alternatif parmak izi reaktiflerinin geliştirilmesi hala önemli bir çalışma alanıdır. Bu çalışmada ekonomik ve aynı zamanda da kullanıcı ve çevre dostu bir parmak izi tespit yönteminin geliştirilmesi amaçlanmıştır. Antrakinonların ve fenollerin amino asitlerle reaksiyonları bilinmektedir. *Aloe vera* L. (AV), antrakinonları ve fenolleri içeren bir bitkidir. Bu çalışmada ticari olarak satılan AV ekstresi tozu (Nurbal, İstanbul) kullanılmıştır. İlk olarak maserasyon yöntemiyle AV'nın kloroform ekstresi elde edilmiş ve bu ekstrenin antrakinon ve fenolik bileşik içerikleri nitel ve nicel olarak analiz edilmiştir. Bu ekstre çözeltisi ile geliştirilen amino asit spotunun 380-540 nm aralığında lüminesans sergilediği tespit edilmiştir. Parmak izi tespitinde en ideal sıcaklık ve konsantrasyon değerlerinin tespiti için optimizasyon çalışması yapılmıştır. Ekstre çözeltisi fotokopi kâğıdı üzerindeki gizli parmak izleri ile daldırma yöntemi ile muamele edilmiş ve ısıya tabi tutulmuştur. Geliştirilen gizli parmak izleri adli ışık kaynağı altında ışınlanırken kırmızı filtre kullanılarak görüntülenmiş ve papil hatlarının net bir şekilde görüldüğü tespit edilmiştir. Bu çalışmada ayrıca AV ekstresinin parmak izi geliştirme kabiliyeti DFO ile kıyaslamalı olarak incelenmiş ve elde edilen sonuçlar AV ekstresinin halihazırda kullanılan parmak izi reaktiflerine alternatif olabileceğini göstermiştir.

Anahtar Kelimeler: *Aloe vera* L., gizli parmak izi, amino asit, parmak izi tespiti, lüminesans.

Teşekkür: Bu çalışma Tokat Gaziosmanpaşa Üniversitesi Bilimsel Araştırma Projeleri Koordinasyon Birimi tarafından 2020/127 numaralı proje kapsamında desteklenmiştir.

Abstract

The gene centre of *Astragalus* species is Eurasia, especially Central and Western Asia and the Sinai-Himalaya regions. The sect. *Malacothrix*, which has 110 taxa in the world, is represented by 90 taxa in Iran, 16 in Turkey and 15 in Russia. 10 of the 16 taxa distributed in Turkey are endemic. In recent years, palynological studies on the genus *Astragalus* have gained importance as supportive tools for understanding species boundaries, especially in taxonomically complex subgroups. Studies on sect. *Malacothrix* and several other groups, have revealed general pollen characteristics such as radial symmetry, trizonocolporate apertures and variable exine ornamentation patterns. Palynological investigation carried out on 16 species belonging to sect. *Malacothrix*. The prepared slides were examined and photographed using a Leica ICC50 HD light microscope. For more detailed information, the JEOL JSM-6060 brand Computer-Controlled Digital SEM (Scanning Electron Microscope) in Gazi University was used. Pollen grains are radially symmetrical, isopolar, trizonocolporate, and operculate. The pollen shape varies: *A. macrostachys* is prolate; *A. stridii* and *A. adiyamanensis* are prolate-spheroidal; and others like *A. argentophyllus*, *A. bakirdaghensis*, *A. mollis*, and others are subprolate. The exine ornamentation is psilate-perforate at the poles, and perforate-reticulate or perforate-rugulate at the equator. The colpus is long, with distinct borders and pointed ends, and the membrane is granular. Despite these characteristics, taxon grouping based on exine ornamentation and pollen shape was not successful, and no effective identification key is created. Consequently, pollen morphology alone is insufficient for distinguishing the species, but can be useful when combined with general morphological traits.

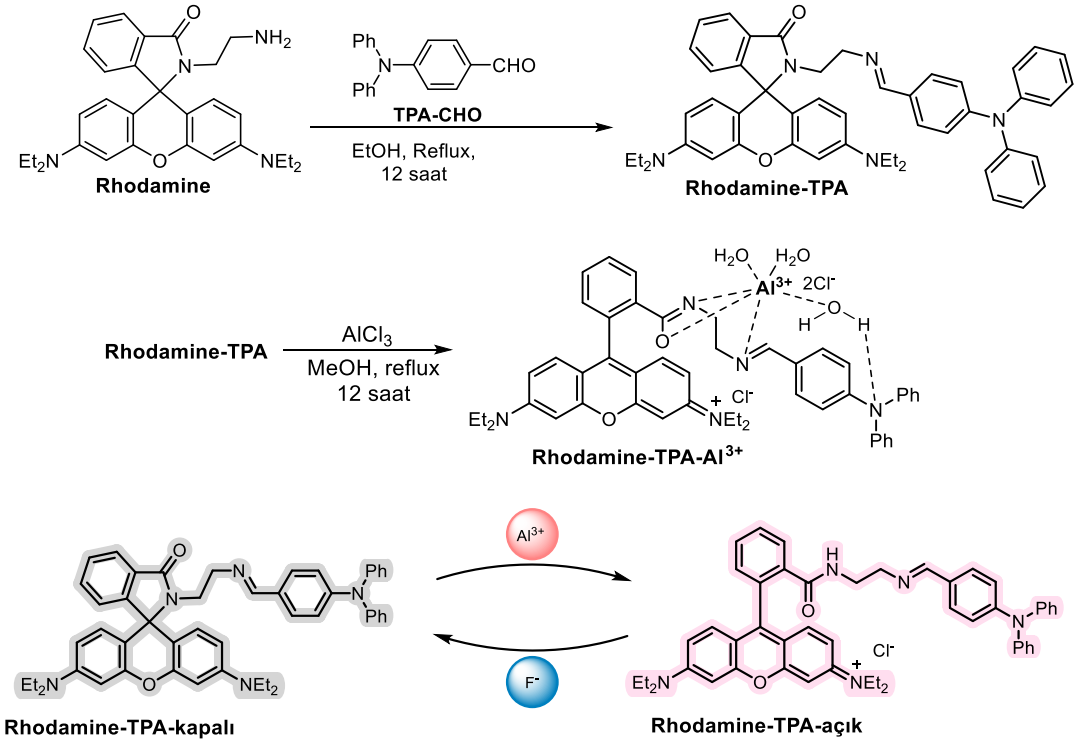
Su içindeki alüminyum ve florür iyonlarının akıllı telefon uyumlu çift tespiti için mono-sübstitüe rodamin sentezi



Sinan Bayindir*, Kemal Yararli

Bingöl Üniversitesi, Fen-Edebiyat Fakültesi, Kimya Bölümü, 12000, Bingöl, Türkiye

Sorumlu yazar e-mail: sbayindir@bingol.edu.tr

Özet

Bu çalışma, gerçek su örneklerinde çift modda çalışan kimyasal bir sensör olarak işlev görebilen mono-sübstitüe-rhodamin (rhodamine -TPA) türevinin sentezi gerçekleştirildi. Rhodamin türevi, alüminyum (Al^{3+}) ile güçlü flüoresan artışı gösterirken, aynı sistemde, Al^{3+} varlığı, florürün (F^-) emisyonu baskılamasına neden olarak florür tespit sınırını belirledi. Bu aynı zamanda probe-aliminyum kopleksinin florür iyonu olarak kullanılabileceği anlamına gelmektedir. Ayrıca, hızlı ve saha dostu kullanım için bu rhodamin türevi, filtre kâğıdı şeritlerine uygulanabilir ve basit RGB analizi ile akıllı telefon kamerası aracılığıyla okunabilir olmasıda ciddi bir avantaş olarak karşımıza çıkmaktadır. Genel olarak, bu özellikler rhodamin türevini alüminyum ve florür seviyelerinin yerinde çevresel izlenmesi için pratik bir araç haline getirmektedir.

Şema 1. Rhodamin-TPA ve kompleksinin sentez stratejileri ve sensör özellikleri

Anahtar kelimeler: Aluminum, Fluoride, RGB-analysis, Rhodamine, Triphenylamine

Abstract

In this study, five different zinc (Zn) chelate complexes derived from EDDHA (F-BD, F-ET, F-TR, F-H, F-OC) were applied to rice (*Oryza sativa* L.) plants to investigate their morphological, physiological, and antioxidant responses under salt stress. Plants were hydroponically grown for 14 days and then exposed to nutrient solutions containing the respective Zn complexes. Salt stress was imposed by applying 150 mM NaCl after two days of treatment. Post-harvest analyses revealed that F-BD and F-ET significantly enhanced root and shoot growth, with F-BD salt treatment showing values close to the Hoagland control. The F-TR group exhibited the highest total chlorophyll content, while F-H and F-ET treatments effectively limited chlorophyll degradation under stress. Proline content increased under saline conditions as an osmoprotective response; however, oxidative stress markers, including H_2O_2 and TBARS levels, were markedly reduced in F-BD and F-H groups. Regarding antioxidant enzyme activities, F-BD and F-TR recorded the highest SOD activity, while F-BD and F-ET displayed the strongest CAT activity. These findings demonstrate that Zn complexes not only support growth parameters but also mitigate oxidative damage by strengthening antioxidant defense, thereby enhancing salt stress tolerance in rice.

Abstract

Lung cancer is the leading cause of cancer-related deaths worldwide, with incidence and mortality continuing to rise, particularly among women. Despite significant advances in treatment, prognosis remains poor, and the five-year survival rate is below 15%. Small Cell Lung Cancer (SCLC) and Non-Small Cell Lung Cancer (NSCLC) are the most clinically distinct subtypes, differing in metastatic potential, treatment response, and overall outcomes. NSCLC, which accounts for the majority of cases, remains challenging to treat, especially in advanced stages. In this study, A-549 cells, a human adenocarcinoma alveolar basal epithelial cell line, were used as an *in vitro* model of NSCLC. Türkiye is rich in medicinal plant diversity, and *Lamiaceae* family is particularly noteworthy due to its wide applications in medicine, food, and cosmetics. *Origanum majorana* L. (*O. majorana*), a prominent member of this family, has essential oils recognized as safe by the Food and Drug Administration (FDA). Plant-derived compounds have long been a source of anticancer agents, as they can reduce toxicity to healthy cells while maintaining therapeutic efficacy. Therefore, the exploration of herbal extracts as alternative or supportive agents in cancer therapy has gained increasing attention. This study compared chloroform, ethanol, and methanol extracts of *O. majorana* for their antioxidant and cytotoxic effects on lung cancer cells. Antioxidant activity was assessed using the DPPH assay, revealing that the chloroform extract exhibited the highest radical scavenging activity (EC_{50} = 0.17 mg/mL) compared to ethanol and methanol extracts. Cytotoxicity was evaluated using the MTT assay, where the methanol extract demonstrated the strongest effect on A-549 cells. All extracts showed statistically significant cytotoxicity compared to untreated controls ($p<0.05$). These findings suggest that *O. majorana* extracts, particularly the methanol and chloroform fractions, possess notable antioxidant and anticancer properties. The study supports further investigation into their potential as complementary therapeutic agents in NSCLC treatment.

Keywords: Lung cancer, *Origanum majorana*, Antioxidant activity, Cytotoxicity, Herbal extracts.

Abstract

Chronic wounds impose a significant global healthcare burden, necessitating the development of advanced wound dressings that are both biocompatible and biodegradable [1]. Among various options, polymer-based wound dressings, particularly those incorporating natural bioactive compounds, have gained increasing attention due to their ability to accelerate healing while minimizing adverse effects [2, 3]. In this study, poly(ε-caprolactone) (PCL), a biodegradable and biocompatible aliphatic polyester, was utilized to fabricate fibrous membranes via electrospinning. To enhance the wound healing functionality of the scaffolds, the nanofiber surfaces were further modified by dip-coating with 1 wt.% hyaluronic acid (HA), a naturally occurring glycosaminoglycan known for its role in tissue hydration and regeneration (PCL/HA). Additionally, curcumin (Cur), a polyphenolic compound with well-documented anti-inflammatory and antimicrobial activities, was incorporated into the PCL matrix to improve the overall bioactivity of the system (PCL-Cur). The morphology of the produced fibers was evaluated using scanning electron microscopy (SEM), confirming the formation of uniform, bead-free nanofibers. Atomic force microscopy (AFM) analysis revealed an increase in surface roughness after curcumin incorporation, rising from 187 ± 36 nm to 245 ± 65 nm. Fourier-transform infrared spectroscopy (FTIR) verified the successful integration of both HA and Cur into the PCL structure. Water contact angle (WCA) measurements demonstrated that HA coating improved surface hydrophilicity. The measured WCA values were 136.0°, 125.4°, 82.1°, and 77.9° for PCL, PCL-Cur, PCL/HA, and PCL-Cur/HA membranes, respectively, indicating enhanced wettability, particularly in HA-coated samples. This study presents a straightforward yet effective approach for designing multifunctional nanofibrous scaffolds by integrating structural polymers, bioactive agents, and surface modifiers. The developed system exhibits promising characteristics for wound healing applications, including enhanced surface properties and biocompatibility.

Abstract

The rise in living standards and the growing awareness of health have prioritized food safety on a global scale and stimulated the development of innovative packaging technologies. During the process from production to consumption, foods undergo microbial, enzymatic, and chemical changes that lead to quality deterioration and safety risks; this not only threatens consumer health but also results in economic losses. Therefore, alternative packaging methods are needed to ensure sustainable food safety. Smart packaging systems have emerged as innovative technologies that provide information about the quality and safety of food. Commonly, freshness, gas, and time–temperature indicators are employed in these systems. In particular, pH-sensitive freshness indicators change color in response to food spoilage, thereby offering consumers visual information about the product's condition. Although synthetic dyes are frequently used in these systems, their toxic effects and potential carcinogenic risks have recently restricted their applications in food-related fields. For this reason, natural pigments are gaining prominence due to their non-toxic, eco-friendly, economical, and easily accessible properties. Natural compounds found in plants, such as anthocyanins and flavonoids, are noteworthy for their purple, red, blue, and pink hues, while other natural pigments including betacyanin, curcumin, and chlorophyll have also been increasingly investigated for use in pH indicator films. This review aims to highlight the importance and potential applications of natural pH indicators in smart packaging systems developed to enhance food safety.

Keywords: Food safety, smart packaging, pH indicators, natural pigments

Abstract

Lettuce (*Lactuca sativa* L.) is an economically and nutritionally important vegetable cultivated worldwide, yet its susceptibility to biotic and abiotic stresses necessitates genetic improvement through biotechnological tools. *Agrobacterium tumefaciens*-mediated transformation is a key approach for genetic modification in lettuce. This study evaluated the influence of nine lettuce cultivars (Caipira, Emocion, Festival, Funtime, Garone, Maritima, Rüzgar, Sürpriz, and Vaidosa) and two *A. tumefaciens* strains (LBA4404 and EHA105) on transformation efficiency using cotyledon explants. A binary vector (pDIRECT_23C, 15,744 bp) carrying CRISPR-Cas9 components and a phosphinothricin (PPT) resistance marker was used as a model to assess DNA delivery, without targeting any specific genomic sequence. Mature seeds were surface sterilized and germinated *in vitro*. Cotyledon explants from seven-day-old seedlings were pre-cultured, inoculated with Agrobacterium suspensions (OD600 = 0.8–1.0), co-cultured in the dark for two days, and transferred to PPT-based selection and regeneration medium. Regenerated shoots were rooted and acclimatized under controlled greenhouse conditions. PCR analysis confirmed transgene integration using BlpR-specific primers. Statistical analysis revealed that EHA105 significantly outperformed LBA4404 in transformation efficiency ($p < 0.05$). Among cultivars, Emocion exhibited the highest number of transgenic shoots, with a transformation efficiency of 5%, followed by Caipira. The relatively large size of the pDIRECT_23C vector demonstrates its suitability as a model for future genome editing studies, where guide RNAs can be inserted for targeted modifications. This study optimized an efficient Agrobacterium-mediated transformation protocol for multiple lettuce cultivars, providing a foundation for functional genomics research and biotechnological improvement. The findings contribute to enhancing transformation efficiency in lettuce, facilitating future CRISPR-based genome editing and crop improvement applications.

Keywords: plant biotechnology, genetic transformation, phosphinothricin selection, cotyledon explant, transgenic shoots, regeneration efficiency

Abstract

Alzheimer's disease (AD), which causes cognitive and sensory deficits due to the loss of structure and function of neurons in the nervous system and the structural and functional degeneration of nerve cells, is a fatal health problem (1,2). AD is a serious problem due to its increasing prevalence in people over the age of 60, where it progresses by causing brain cell destruction, and the difficulties in its treatment (3). The most fundamental cause of the disease's pathological findings is a deficiency in the levels of neuromediators known as acetylcholine (ACh) and butyrylcholine (BCh) in the brains of patients. Inhibition of AChE and BChE, the widely distributed cholinesterase enzymes, increases the amount of acetylcholine and is known to increase cholinergic activity (4). AChE has led to the development of many drugs currently in clinical use for the treatment of AD. Studies are ongoing to investigate the problems and side effects of overuse of existing drugs (5). Natural products are gaining prominence for the treatment of Alzheimer's disease (6). Mushrooms are known to be used in alternative medicine for the treatment of many diseases. *Ganoderma lucidum* (Curtis) P. Karst (GL), belonging to the Ganodermataceae family, is one of the most traditional medicinal plants. The literature has reported positive effects of extracts, such as the polysaccharides and triterpenes present in GL, in protecting against neurological diseases such as Alzheimer's (7). In this study, the in vitro inhibitory effects of GL (from human blood) on AChE and BChE enzyme activities were investigated. IC_{50} values were calculated from the activity (%)-[GL] graph. The IC_{50} values of GL for AChE were calculated as 69.3 µg/mL (r2: 0.9551) and for BChE as 69.3 µg/mL (r2: 0.9713). The IC_{50} values of GL showed mild inhibitory activity on both enzymes compared to the standard substance.

Abstract

Polypropylene (PP) is one of the most widely used thermoplastics due to its low cost, lightweight, and ease of processing. However, its relatively low stiffness and thermal resistance restrict its applications in structural and high-temperature environments. Hence, the study on PP-based composites with activated carbon (AC) at different loadings (0.5–5 wt.%) was carried out using a twin-screw extrusion process followed by injection molding. The influence of AC addition acting as a nucleating agent on crystallization behaviour, mechanical properties, impact resistance, density, and thermal performance was systematically investigated. This effect contributed to improved mechanical properties, such as increases in tensile modulus by up to 33% and flexural modulus by 29%, which are consistent with observations that ACs reinforce polymer matrices by restricting molecular mobility and improving crystalline structure. At higher concentrations, further improvements in stiffness were achieved; however, these gains are accompanied by a reduction in toughness, as evidenced by the decline in Charpy notched impact strength, suggesting a partial embrittlement effect. Furthermore, the progressive increase in density with increasing AC content, along with the marked enhancement in thermal performance demonstrated by the rise in Vicat softening temperature from 99°C to 106°C reflected the characteristic influence of carbonaceous fillers in reinforcing polypropylene (PP) nanocomposites and improving their thermal resistance. To conclude, the incorporation of AC into PP matrix significantly enhanced its stiffness and thermal resistance, as evidenced by improvements in tensile and flexural moduli as well as Vicat softening temperature for tailoring the structure–property relationships of PP, broadening its potential applications in lightweight and thermally demanding environments.

Abstract

Corrosion is a physicochemical interaction between metals and their environment, resulting in property degradation and potential system failures. Among various prevention strategies, protective coatings are considered highly effective. Epoxy resins are widely utilized due to their excellent mechanical strength, toughness, and resistance to chemicals, moisture, and corrosion. This study focuses on the development of a smart composite epoxy coating with self-healing and anti-corrosive properties, reinforced with chitosan (CS) and halloysite nanotubes (HNT). The self-healing mechanism relies on microcapsules containing reactive agents embedded within the polymer matrix. CS, a natural, non-toxic, and eco-friendly cationic polysaccharide, and HNT, a tubular nanomaterial derived from rolled kaolinite layers, synergistically enhance the coating's performance. The hollow structure of HNT contributes to mechanical reinforcement, while the hydroxyl and amino groups in CS promote strong interactions with the epoxy matrix. CS-modified HNT capsules are synthesized and characterized using SEM and FTIR. Coatings are prepared via dip-coating on bare metal substrates, including pure epoxy, CS-HNT epoxy, and CS-HNT loaded with corrosion inhibitors. To assess self-healing capability, coatings are deliberately damaged and subjected to salt test. Damage recovery is monitored via optical microscopy, and corrosion resistance is evaluated using Electrochemical Impedance Spectroscopy (EIS). The goal is to develop a durable, long-lasting coating material with enhanced protective performance, contributing to the advancement of corrosion-resistant technologies.

Keywords: Epoxy resin, composite coatings, corrosion protection, self-healing coatings, smart materials.

Özet

Rotavirus, buzağılarda ciddi ishal ve yüksek ölüm oranlarına neden olan ve insanları da etkileyebilen önemli bir patojendir. Daha önce, yerel olarak üretilen antikorlar kullanılarak geliştirilmiş bir multi-tanı kiti, ELISA, Western Blot, SDS-PAGE ve PCR gibi geleneksel yöntemlerle doğrulanmıştır ancak elektro-kimyasal doğrulama yapılmamıştır. Bu çalışmada, yerli üretim antikorların kullanıldığı VP6 Rotavirüs proteinine yönelik tanı kitinin elektrokimyasal yöntemlerle validasyonu gerçekleştirilmiştir. Çalışma kapsamında kullanılacak olan yüzey baskılı karbon elektrotlar (SPE) kullanılarak immünosensörler için optimizasyonlar yapılacaktır. Antikor immobilizasyonu için gerekenen uygun koşulların belirlenmesi için farklı pH, sıcaklık ve inkübasyon sürelerinin blokaj ve antijen bağlanma aşamaları üzerine etkileri diferansiyelpulsvoltametrisi (DPV), döngüselvoltametri (CV) ve elektrokimyasal impedans spektroskopisi (EIS) ile incelenecektir. Optimizasyon çalışmaları sonucunda immünosensörlerin en uygun pH, sıcaklık ve inkübasyon süresi değerleri kullanılarak LOD, LOQ ve RSD belirleme aşamalarına geçilecektir.

Abstract

The most common subtype in pancreatic cancer is pancreatic adenocarcinoma (PAAD). Patients with PAAD experienced poor clinical outcomes because they are diagnosed lately and there are a few effective treatment options. Therefore, diagnostic and prognostic biomarkers are required urgently. Disruption of cellular processes are associated with cancers, and *MARK* family members (*MARK1, MARK2, MARK3, MARK4*) have cellular activities, such as cell-cycle control and intracellular signal transduction. It is reported that *MARK* family members have been implicated in lung cancer, hepatocarcinoma, and leukaemia, but their roles are not comprehensively investigated in PAAD. Therefore, possible biological and prognostic impacts of this family on PAAD were examined here**.** GEPIA2, UALCAN, and GUOLAB, which are publicly available bioinformatic tools, were used to study gene/protein levels, prognostic importance, and immune infiltration of the *MARK* members. GEPIA2 tool showed higher mRNA expression levels of *MARK2* and *MARK4* in PAAD tumour samples (n=179) when compared to normal samples (n=171) (p<0.05), but not for *MARK1* and *MARK3*. Protein expression levels of all members were statistically different between PAAD tumour (n=137) and normal samples (n=74), generated by UALCAN platform. Interestingly, GEPIA2 platform indicated better overall survival for patients with high mRNA expression of *MARK1* (n=60, hazard ratio=0.45, p=0.0021) and worse survival for those with high mRNA expression of *MARK2 (*n=60, hazard ratio=1.7, p=0.047*)*, compared to patients in opposite groups. Also, GUOLAB tool demonstrated that *MARK1* mRNA expression were positively correlated with $CD4^+$ (cor=0.40, p<0.001) and MAIT (cor=0.35, p<0.001) cells, and *MARK2* expression were positively correlated with nTreg (cor=0.33, p<0.001) and neutrophil (cor=0.30, p<0.001) cells. In short, the bioinformatic analyses showed that only *MARK2* was both differentially expressed and prognostically significant in PAAD. *MARK*-related cellular mechanisms might be important in PAAD, therefore; further investigations are needed for the potential drug development.

Keywords: *MARK*, biomarker, PAAD, prognosis

Abstract

Water covers approximately 71% of the Earth's surface and is one of the most essential elements for the survival of all living organisms. However, water resources and quality are increasingly under threat due to industrialization, urbanization, population growth, climate change, and agricultural activities (1). In particular, the discharge of synthetic dyes from textile and related industries into aquatic environments has caused serious water pollution problems. These pollutants are resistant to biodegradation, persistent in the environment, and pose significant risks to ecosystems and human health (2). Therefore, the dye industry must treat its wastewater with appropriate methods before discharging it into the environment (2). In this study, membrane structures were prepared by the polymerization of a biocompatible monomer, 2-hydroxyethyl methacrylate (HEMA), with 4-vinyl benzoic acid (4-VB), and the removal of a model cationic dye, Crystal Violet (CV), was investigated. Characterization of the prepared membranes was carried out using SEM-EDS, FTIR analyses, and swelling tests. Adsorption studies were evaluated by considering parameters such as initial dye concentration, pH, temperature, and contact time. Preliminary findings indicate that the developed p(HEMA)-4-VB-based membrane structures have potential as effective adsorbents for CV removal. Overall, this study may contribute to the development of environmentally friendly and reusable polymeric membranes for the removal of cationic dyes from aquatic environments.

Abstract

In this study, eight soil samples were collected from agricultural lands irrigated by wastewater and drainage water along the main wastewater discharge channel in Konya. Of these, seven were irrigated with wastewater and one with drainage water using the sprinkler method. X-ray fluorescence (XRF) analysis was conducted to determine the total chemical composition of the soils. Among the oxide forms, CaO (27–37%) and SiO_2 (24–28%) were found to be the most abundant. The Ca/Mg ratios were notably high, which was associated with the loose structure of the soil. Principal Component Analysis (PCA) of the results revealed that the total explained variance was 63.13%. According to the analysis, the available Fe, Mg, Pb, Cu, and Ni contents were identified as differentiating factors. It was also determined that as Fe and Mg concentrations increased, the values of soil organic matter (SOM), Ca, K, and Mn tended to decrease. The soils under investigation were characterized by very high CaCO3 content and moderate levels of SOM. While no salinity problems were observed in soils irrigated with wastewater, salinity was detected in the soil irrigated with drainage water (2.95 dS/m). The concentrations of heavy metals (Ni, Cd, Pb) were below toxic thresholds. Among the essential plant nutrients, K, Ca, and Mg levels were found to be very high, total N content was high, and available P was at a sufficient level. Regarding micronutrients, Fe, Zn, and Mn levels were low, while Cu was moderate. Phenological observations made during sampling in fields cultivated with alfalfa, oats, maize, wheat, and sunflower indicated no signs of toxicity in the crops.

Abstract

Cancer has become a serious health concern recently, endangering people everywhere. The most promising cancer treatment approach recently, aside from conventional approaches, is photodynamic therapy (PDT). As photosensitizers, phthalocyanines (Pcs) have been widely employed in PDT due to their strong ability to generate singlet oxygen and other special qualities. Therefore, in this study, photophysicochemical properties such as fluorescence, singlet oxygen, and photodegradation quantum yields were investigated to determine their potential use as photosensitizers in PDT. According to the findings, zinc phthalocyanines show the therapeutic effectiveness of photophysicochemical techniques and have the potential to be employed as photosensitizers in photodynamic therapy. The zinc phthalocyanines that are produced are regarded as promising in vitro PDT agents for further research [1].

Abstract

A novel thioester-based polymer was synthesized and evaluated as a biodegradable carrier for drug delivery. The polymer was prepared via a thiol–Michael addition reaction between 1,6-hexanediol diacrylate and α-lipoic acid under UV irradiation for 3 hours, forming a thioester backbone containing free carboxyl groups. These free carboxyl groups were subsequently conjugated with tryptophan through a DCC-mediated coupling reaction to enhance amphiphilicity and introduce biointeractive aromatic moieties. The chemical structure of the synthesized polymer was confirmed by FTIR spectroscopy, which verified the formation of thioester linkages and amide bonds following tryptophan conjugation. Nanoparticles were obtained by nanoprecipitation using DMSO as the organic solvent and deionized water as the non-solvent. Blank nanoparticles exhibited an average diameter of 71.1 ± 2.1 nm, a PDI of 0.183 ± 0.052, and a zeta potential of –18.0 ± 1.2 mV. Curcumin-loaded nanoparticles showed a size of 123 ± 2.5 nm, PDI 0.136 ± 0.02, zeta potential –15 ± 1.2 mV, and 46% loading efficiency. GPC analysis revealed a number-average molecular weight (Mn) of 3.05 kDa and a weight-average molecular weight (Mw) of 3.95 kDa with a PDI of 1.29, confirming the formation of a narrowly distributed, low-molecular-weight thioester polymer. In vitro release experiments demonstrated a faster release in mildly acidic medium (pH 5.0) compared to physiological pH (7.4). Cumulative curcumin release reached 50.9%, 68.9%, and 100% at 24, 48, and 120 hours at pH 5.0, while corresponding values at pH 7.4 were 44.0%, 55.2%, and 71.8%. The enhanced release under acidic conditions was attributed to acid-facilitated hydrolysis of thioester linkages, leading to gradual network loosening and improved diffusion. Overall, this tryptophan-functionalized thioester polymer derived from lipoic acid represents a promising new class of degradable materials capable of sustained and environmentally responsive drug release, offering potential advantages for targeted cancer therapy.

Keywords: α-lipoic acid, thioester polymer, tryptophan, curcumin

Abstract

β-glucan is a polysaccharide composed of D-glucose units, and its structure varies among organisms. In cereals, it is linear with β-1,3 and/or β-1,4 bonds; in bacteria, it is linear with β-1,3 bonds; and in yeast, it has a branched structure with a β-1,3 backbone and β-1,6 side chains. In *Saccharomyces cerevisiae*, β-glucan is mainly located in the cell wall, comprising about 50% as β-1,3-glucan and 15% as β-1,6-glucan. Extraction can be carried out by hot water, alkaline solutions, enzymatic treatment, or mechanical disruption, each providing different yields. Yeast-derived β-glucans are applied in food as dietary fiber and cholesterol-lowering agents, in pharmaceuticals as immune stimulants, and in cosmetics to improve skin hydration. They enhance immune activity, reduce cholesterol, regulate blood sugar, and lower infection risk. To reduce costs, attention has turned to renewable substrates such as sugarcane molasses, which is rich in sugars and minerals. The aim of this study was to evaluate the effect of molasses concentration and fermentation period on β-glucan production in yeast. *S. cerevisiae* was grown in Cooper & Paddock medium with 2-10% (v/v) sugarcane molasses as carbon sources. β-glucan yields were monitored during fermentation. Extraction was performed using an eco-friendly sonication method combined with mild acid–alkali treatment, and functional groups were characterized by Fourier-transform infrared spectroscopy. At 2% molasses, the maximum yield was 0.108 mg/mL DCW on day 2. At 5%, the highest yield was 0.676 mg/mL DCW after 1.5 days, followed by a decline. The best results were with 10% molasses, reaching 0.903 mg/mL DCW on day 1 and remaining above 0.6 mg/mL until day 4. In conclusion, the study demonstrated that sugarcane molasses is a promising low-cost substrate for β-glucan production by *S. cerevisiae.* Furthermore, it suggests its potential use in the food industry as a dietary fiber source.

Abstract

Mannoproteins are structural polysaccharides located in the outer layer of the yeast cell wall, consisting of a protein backbone covalently linked to mannose residues. In *Saccharomyces cerevisiae*, they play a crucial role in maintaining cell wall integrity, adhesion, and stress tolerance, while also showing functional properties such as immunomodulation, emulsification, and antioxidant activity. Owing to these properties, yeast mannoproteins find applications in the food industry as stabilizers and prebiotics, in pharmaceuticals as immune enhancers, and in cosmetics for skin protection. For sustainable and cost-effective production, agro-industrial byproducts such as sugarcane molasses have been considered as alternative carbon sources due to their high sugar and mineral content. This study aimed to investigate how molasses concentration and fermentation time affect mannoprotein production by *S. cerevisiae*. The yeast was grown under submerged fermentation using 2–10% (v/v) sugarcane molasses as a carbon source. Mannoprotein was extracted by alkaline–sonication-thermal treatment. Biological activity of extractracted mannoprotein was confirmed via oil spreading and emulsification index (EI). Morever, its structural properties were verified by Fourier-transform infrared spectroscopy (FTIR). In conclusion, increasing molasses concentration improved both cell growth and mannoprotein yield, reaching the best results at 5% molasses. Fermentation time also influenced production, with the highest yield observed at the early stationary phase (2 days). On the other hand, it exhibits an oil spreading activity of 8 cm, EI of 40%, and retains 96% of its EI after 48 hours. The FTIR spectra showed characteristic peaks of polysaccharides and proteins, confirming the presence of mannose and peptide groups of mannoproteins. These results show that sugarcane molasses can be used as an economical substrate for mannoprotein production by *S. cerevisiae*, supporting sustainable bioprocess applications.

Abstract

The development of electrochemical stimuli-responsive drug delivery systems is of both academic and industrial interest due to the ease with which it is possible to trigger payload release, providing drug delivery in a controllable manner. Herein, the preparation of in situ forming injectable hydrogels including electroactive polypyrrole nanoparticles (PPy-NPs) where of Sr^{2+} ions are electrochemically loaded for electrically triggered release of Sr^{2+} ions is reported. The hydrogels were characterized by a variety of techniques including Fourier-transform infrared (FTIR) spectroscopy, scanning electron microscopy (SEM), energy dispersive X-ray spectroscopy (EDX), thermogravimetric analysis (TGA), X-ray diffraction (XRD), cyclic voltammetry (CV), etc. The cytocompatibility towards human mesenchymal stem cells (MSCs) and fibroblasts were also studied. The Sr^{2+} ions loaded PEC-ALD/CS/PPy-NPs injectable hydrogel showed no significant cytotoxicity towards human mesenchymal stem cells (MSCs) and fibroblasts. Sr^{2+} ions were electrochemically loaded and released from the injectable electroactive hydrogels, and the application of electrical stimulus enhanced the release of Sr^{2+} ions from gels by ca. 2–4 fold relative to the passive release control experiment. The antibacterial activity of Sr^{2+} ions against *E.coli* and *S.aureus* was demonstrated in vitro. Although these prototypical examples of Sr^{2+} loaded electroactive gels don't release sufficient Sr^{2+} ions to show antibacterial activity against *E. coli* and *S. aureus*, we believe future iterations with optimised physical properties of the gels will be capable of doing so.

Keywords: injectable electroactive hydrogel, divalent ion release, bone infection.

Abstract

This study aimed to evaluate the fatty acid composition, nutritional energy value, and antimicrobial activity of *Nigella sativa L.* seed oil obtained by supercritical carbon dioxide (SC–CO_2) extraction. The method provides an environmentally friendly and efficient alternative to conventional solvent extraction, ensuring high oil quality and the preservation of bioactive compounds. *Nigella sativa L.* seed oil is a valuable natural product rich in unsaturated fatty acids, thymoquinone and tocopherols, known for their nutritional and therapeutic effects. The SC–CO_2 extraction technique offers solvent-free processing under mild conditions, reducing oxidation and degradation of thermolabile compounds. This study investigates the chemical and biological characteristics of SC–CO_2-extracted *Nigella sativa L.* oil. Seeds were extracted at 420 bar and 47 °C for 120 minutes using SC–CO_2. Fatty acid composition was determined by gas chromatography (GC–FID). Nutritional energy was calculated according to standard macronutrient conversion factors. Antimicrobial activity was assessed by the microdilution method against *Escherichia coli, Staphylococcus aureus* (MRSA), and *Candida albicans*, with results expressed as minimum inhibitory concentration (MIC). Linoleic (53.8%), oleic (22.3%), and palmitic (13.6%) acids were identified as the major components, with total unsaturated fatty acids exceeding 80%. The oil's energy value was approximately 895 kcal/100 g. Antimicrobial tests showed strong inhibitory effects, with MIC values of 6.25 mg/mL for *E. coli*, 3.12 mg/mL for *S. aureus*, and 12.5 mg/mL for *C. albicans*. These results indicate that SC–CO_2 extraction preserves both nutritional and functional properties. SC–CO_2 extraction produces high-quality *Nigella sativa L.* seed oil with rich unsaturated fatty acid content, high caloric value, and significant antimicrobial potential. This method offers a sustainable and effective approach for food, cosmetic, and pharmaceutical applications.

Keywords: *Nigella sativa* L., supercritical CO_2 extraction, fatty acid composition, nutritional value, MIC.

Abstract

In this study, an alkaline serine protease, Subtilisin Carlsberg (SC), produced by Bacillus licheniformis, was immobilized onto a biochar-chitosan composite carrier synthesized from waste vineyard biomass. The composite material was prepared by integrating biochar into a chitosan matrix and activated with glutaraldehyde to enable covalent enzyme attachment. The structural and morphological properties of the composite carrier were characterized by SEM and TGA analyses. The immobilized enzyme exhibited optimum catalytic activity at pH 8.0 and 50 °C, showing similar behavior to the free enzyme. Kinetic studies revealed that immobilization slightly altered the apparent Km and Vmax values but significantly enhanced thermal and operational stability. These findings demonstrate that the biochar–chitosan composite provides a stable and efficient immobilization matrix, improving enzyme reusability and maintaining catalytic performance under variable conditions. The results highlight the potential of this bio-based composite carrier as a sustainable material for immobilized enzyme systems in biotechnological applications.

Keywords: Subtilisin Carlsberg, Biochar, Chitosan, Enzyme kinetics

Abstract

In this study, tomato pomace obtained from Rio Grande processing tomatoes was dried using hot air (50, 60, and 70 °C) and microwave (240 W and 400 W) methods to produce tomato pomace powders with particle sizes smaller than 1000 µm. The effects of different drying conditions on physicochemical, bioactive, and physical quality properties as well as energy efficiency were comprehensively evaluated. The fresh tomato pomace showed a moisture content of 90.64%, soluble solid content of 11.66%, pH of 4.69, and titratable acidity of 1.37% (as citric acid equivalent). The drying method had a statistically significant effect on color parameters ($p<0.05$). The highest L*, a*, and b* values were obtained from samples dried at 70 °C (hot air) and 240 W (microwave). Regarding powder properties, the highest water holding capacity (1105.56%) was found at 50 °C. The lowest Carr index (14.26%) and Hausner ratio (1.17) were observed in the sample dried at 240 W, indicating better flowability and lower cohesiveness; however, the lowest water holding capacity was also recorded for this condition. Bioactive compounds varied significantly depending on the drying conditions. Total phenolic content ranged from 154.21 to 427.81 mg GAE 100 g^{-1} DM, and antioxidant activity ranged between 0.76 and 1.63 mmol TE 100 g^{-1} DM. Both total phenolic content and antioxidant activity decreased under hot air-drying conditions. Moreover, ascorbic acid and carotenoid contents also declined after drying; however, hot air drying at 70 °C was statistically more effective in preserving these compounds compared with other conditions. Drying kinetics were best fitted by the Midilli–Kucuk, Weibull, and Artificial Neural Network (ANN) models. The drying rate, effective moisture diffusivity, and mass transfer coefficients increased with higher temperature and microwave power. The lowest specific energy consumption (2.06 kWh kg^{-1} water) was obtained during microwave drying at 400 W. Overall, hot air drying at 70 °C provided the most favorable results in terms of color, powder characteristics, and bioactive compound retention. The findings suggest that drying tomato pomace by hot air is a promising approach for producing functional powders suitable for use as food ingredients. Additionally, the current study was supported by Giresun University Coordinatorship of Scientific Research Projects (Grant number: FEN-BAP-A-110225-26).

Abstract

Recently, metal nanoparticles have been widely utilized in biotechnology and medicine due to their advantages, including low cost, eco-friendly synthesis processes, and biocompatibility. In this study, silver oxide (Ag_2O) nanoparticles were synthesized using a green synthesis approach from the fresh cones of *Cedrus libani* extract, and their antibacterial activities were evaluated. The plant extract acted as both a reducing and stabilizing agent, providing an environmentally friendly synthesis medium (Das et al., 2020). Characterization of the synthesized Ag_2O nanoparticles was performed using X-ray Diffraction (XRD) for crystalline structure analysis, Fourier-Transform Infrared Spectroscopy (FTIR) for functional group analysis, and Scanning Electron Microscopy (SEM) for morphological examination (Dawadi et al., 2021). The antibacterial activity was assessed using the well diffusion method against *Bacillus subtilis*, *Staphylococcus aureus*, *Enterococcus faecalis*, *Staphylococcus epidermidis*, *Salmonella typhimurium*, and *Escherichia coli* (Atacan et al., 2021). The highest antibacterial activity was observed on *S. typhimurium* and *B. subtilis* bacteria (13 mm), followed by *E. coli* and *S. epidermidis*. The lowest activity was recorded against *S. aureus* and *B. subtilis*. These results demonstrated the potent antibacterial properties of the synthesized Ag_2O nanoparticles (Kumar et al., 2021). In conclusion, Ag_2O nanoparticles produced from *Cedrus libani* cones present a promising, sustainable, and biocompatible alternative for the development of antibacterial nanomaterials.

Abstract

In the present study, literature on the determination of propranolol in various sample matrices have been reviewed. The analytical methods developed in these studies are expected to be sensitive, rapid, simple, and cost-effective. In all methods, accuracy was evaluated through parameters such as linear range, limit of detection, and recovery rates, while precision was assessed based on standard deviations obtained from intra-day and inter-day repeated analyses. The validity of the developed methods was demonstrated through the testing of relevant validation parameters. In the reviewed studies, propranolol was determined in pharmaceutical preparations, wastewater, human and animal plasma, post-mortem tissues and body fluids, and urine, either alone or in the presence of other active substances. Depending on the sample matrix analyzed, different extraction methods were applied, and in most studies, extraction efficiency was calculated and reported. Liquid chromatography was commonly employed, and it was observed that the sensitivity of the method varied depending on the type of detector used. Furthermore, it was reported that methods such as LC-MS, LC-MS/MS, and LC-QQQ-MS/MS enhanced sensitivity and reduced analysis time.

Abstract

In this study, an ion-exchange polymeric adsorbent was prepared by modifying chloromethyl polystyrene (CMS) particles with 3-(dimethylamino)-1-propylamine (DMAPA) to introduce amino functional groups. The resulting adsorbent is hereafter referred to as DMAPA-m-CMS. The chemical structure of the synthesized material was characterized using FTIR, SEM, and XPS analyses. The adsorption performance of DMAPA-m-CMS toward As(V) and Se(VI) ions was systematically evaluated in a batch system under various conditions, including the effects of pH, contact time, initial concentration, competing anions, and ionic strength. The maximum experimental adsorption capacities were determined as 26.26 mg As(V)/g polymer at pH 4.0 and 26.02 mg Se(VI)/g polymer at pH 4.0. Adsorption kinetics followed the pseudo-second-order model, indicating that the adsorption process was governed by chemisorption involving valence forces through electron sharing or exchange between adsorbent and adsorbate. Equilibrium data were well described by the Langmuir isotherm, and according to the Langmuir model, the maximum theoretical adsorption capacities at 25 °C were calculated as 111.11 mg As(V)/g polymer and 83.33 mg Se(VI)/g polymer. Overall, the developed adsorbent exhibited high adsorption capacity and selectivity for both As(V) and Se(VI) ions, even in the presence of competing species. These results demonstrate that DMAPA-m-CMS is a promising and sustainable adsorbent for the removal of toxic arsenic and selenium ions from contaminated water, contributing to environmental protection and the advancement of water treatment technologies.

Özet

Osmanlı Devleti'nde Edirne'de ilk gül yağı üretiminin 13. veya 17. yy.da başladığı düşünülmektedir. 1877-78 Türk-Rus savaşı (93 harbi) sonrasında imzalanan Berlin Antlaşması'nı (1878) takip eden yıllarda, Edirne Vilâyeti'ne bağlı olup yağ gülcülüğünün merkezi olan Kızanlık ve çevresindeki toprakların kaybedilmesinin ardından Osmanlı Devleti Anadolu'da yağ gülcülüğünü teşvik etmiştir. 1901'de (Hicri 1319) yayımlanan *Gülistan Tesisi ve Tımarına ve Gül Yağı Takdir ve İmaline Dair Risaledir* isimli kitapçıkta yağ gülcülüğü hakkında bilgiler verilmiştir. Bu çalışmada, bahsedilen kitapçık incelenerek gül yağı istihsali yöntemi günümüzde uygulanan endüstriyel distilasyon ile karşılaştırılmıştır. Öncelikle Osmanlı Türkçesiyle yazılmış olan ilgili kitapçık günümüz Türkçesine çevrilmiştir. Osmanlı döneminde gül yağı distilasyonuna ilişkin bilgiler bu kitapçığa dayanmaktadır. Günümüzde gerçekleştirilen endüstriyel distilasyona ilişkin bilgiler ise Göller Yöresinde yağ gülcülüğü üzerine daha önce tarafımızdan yürütülmüş çalışmalar sırasında yapılan saha gözlemlerine dayanmaktadır. Osmanlı döneminde gül yağı istihsali için *Rosa damascena* çiçekleri bakır imbiklerde su ile distilasyona tabi tutulmuştur. Her seferinde yaklaşık 7,5 kg çiçek kaynatılabilen bu sistemde, kaynayan su buharının çiçeklerdeki uçucu bileşenleri de alarak soğuk su içerisinden geçirilmiş olan islim borusundan geçirilerek yoğunlaşması sağlanmış ve boru ucuna bağlanmış olan yaklaşık 7,5 L'lik şişelerde biriktirilmiştir. Her kazandan 2 şişe (birinci şişe baş, ikinci şişe ayak olarak adlandırılmıştır) olmak üzere dört kazandan alınan yaklaşık 60 L yağlı su ikinci kez distilasyona tabi tutulmuş ve bu kez islim borusunun ucuna bağlanan kristal sürahilerde biriktirilmiştir. Biriken yağlı suyun üzerinde toplanan gül yağı kepçe yardımıyla alınmıştır. Günümüzde endüstriyel distilasyonda ise 3000 L'lik bakır tanklarda tek seferde 500 kg gül çiçeği işlenebilmektedir. Uçucu bileşenleri taşıyan su buharı soğutucu kondenserden geçerek önce distilat tankına oradan da florentin kabına geçer. Florentin kabının cam haznesinde toplanan yağa birinci yağ (çiçek yağı) denir. Geriye kalan yağ altı suyu biriktirilerek sonradan tekrar distilasyona tabi tutulur. İkinci distilasyonda üretilen yağa ikinci yağ (su yağı) denir. Genellikle %25 birinci yağ + %75 ikinci olacak şekilde karıştırılarak ticari gül yağı elde edilmektedir.

Anahtar kelimeler: Distilasyon, Gül yağı, *Rosa damascena*, Osmanlı Devleti, Yağ gülcülüğü

Abstract

The development of biodegradable, polymer-based bioactive cosmetic masks that promote skin health and environmental sustainability has gained increasing attention in recent years. Conventional cosmetic masks often contain synthetic polymers and chemical additives, which may cause skin irritation and contribute to environmental pollution. Furthermore, bioactive agents including supporting skin health, such as antioxidants, moisturizers, and soothing compounds are essential to obtain a preferred skin care cosmeceutical. This study aims to develop a new generation of cosmetic masks using biodegradable polymers and natural bioactive ingredients. In this research, hydrogel masks were prepared via the casting method by incorporating bioactive components and clay into polyvinyl alcohol (PVA). The flexibility of the mask formulation was enhanced by adding plasticizers. The produced masks characterized by mechanical testing and bioactivity analysis. The incorporation of bioactive ingredients enhanced the antioxidant activity of neat films. It was determined that there was a decrease in tensile strength and elongation with the addition of the bioactive additive compared to the control sample.The proposed formulation offers a novel approach by combining biodegradability with targeted bioactivity, addressing the dual need for skin health improvement and ecological responsibility. This research is expected to contribute to the development of next-generation cosmetic materials that are environmentally sustainable, biocompatible, and suitable for commercial applications.

Keywords: Biodegradable polymers, bioactive cosmetic masks, environmental sustainability, skin health, polymer characterization.

Abstract

The exploration of microbial survival strategies in extraterrestrial environments is fundamental to both astrobiology and planetary protection. *Bacillus subtilis* is a well-characterized Gram-positive bacterium with remarkable genetic plasticity and stress tolerance. It has been considered as a model organism for space biology research. Previous research has proven its resilience against extreme conditions, including radiation, dehydration, and low-pressure environments. Its endurance to such stress conditions makes it an ideal system to investigate microbial resilience under Martian-like conditions. Among the environmental parameters on Mars, the weak and heterogeneous magnetic field has received comparatively little attention despite its potential role in shaping microbial physiology. Studies under low and static magnetic field conditions suggest significant impacts on oxidative stress balance, DNA repair mechanisms, and ion homeostasis. In *B. subtilis*, these processes are tightly regulated by sigma factors and global transcriptional regulators, which coordinate adaptive gene expression programs in response to environmental cues. Integrating evidence from microbial stress biology and magnetic field research, we propose that *B. subtilis* serves as a valuable platform for predicting how terrestrial life may respond to Martian magnetic conditions. Such insights not only enhance our understanding of microbial adaptability in space but also provide essential knowledge for the safe design of future planetary exploration missions. Due to its hardiness and spore-forming ability, *B. subtilis* present itself as a valuable model organism in both agricultural biotechnology applications on Earth and astrobiology studies.

Abstract

Apigenin (4′,5,7-trihydroxyflavone) is a naturally occurring flavonoid found in a variety of fruits, vegetables, and medicinal plants. It has gained considerable attention due to its potent antioxidant and anticancer properties. This study aims to investigate the molecular mechanisms that underlie the bioactivity of apigenin through a computational approach that integrates density functional theory (DFT), molecular docking, and ADMET analysis. We calculated the optimized molecular geometry and electronic parameters, including the HOMO–LUMO energy gap, ionization potential, and electronegativity, to evaluate the radical-scavenging capacity and redox reactivity of apigenin. The DFT results indicate robust chemical stability and effective electron-donating ability, which support the antioxidant function of apigenin. Molecular docking simulations were conducted against cancer-related targets such as PIM1 kinase and the CD47 receptor to explore the inhibitory interactions at their active sites. Apigenin exhibited strong binding affinities through hydrogen bonding and π–π stacking with key amino acid residues, suggesting a potential to suppress oncogenic pathways. Furthermore, pharmacokinetic (ADMET) predictions revealed favorable absorption and low toxicity profiles, reinforcing the drug-likeness of apigenin. These computational findings highlight the dual antioxidant and anticancer potential of apigenin, underscoring its significance as a natural, safe, and effective therapeutic agent. This study provides valuable insights into the electronic and structural factors that influence flavonoid bioactivity and advocates for further in vitro and in vivo validation.

Keywords: Apigenin, flavonoid, DFT, antioxidant, anticancer, molecular docking.

Abstract

Pyroptosis is a lytic form of pro-inflammatory programmed cell death mechanism characterized by the formation of pores in plasma membrane, and non-vesicular release of pro-inflammatory cytokines including IL-1β and IL-18. Recent studies have showed that S-palmitoylation of human GSDMD at cysteine 19 is a key regulatory step controlling both GSDMD activation and interaction with membranes (membrane translocation) in pyroptosis. In other words, S-palmitoylation of GSDMD at this amino acid has been shown to be required for pore formation by GSDMD oligomerization in pyroptosis. S-palmitoylation of cysteine residues, catalyzed by a family of 23 ZDHHC protein palmitoyltransferases (i.e. protein acyltransferases), is the most common lipid modification of membrane-associated proteins, such as GSDMD. Since pyroptosis of granulosa cells is involved in the pathogenesis of PCOS, and palmitoyltransferases such as ZDHHC5, ZDHHC7 and ZDHHC9 mediate GSDMD palmitoylation to induce pyroptosis, cellular levels of palmitoyltransferases and their regulation might be important for granulosa cells pyroptosis in the context of PCOS. Here, transcript levels of ZDHHC protein palmitoyltransferases in granulosa cells were compared between PCOS and non-PCOS women using publicly available transcriptomics datasets. Among 23 ZDHHC palmitoyltransferases, it was found that mRNA levels of ZDHHC6, ZDHHC18 and ZDHHC24 are significantly increased in granulosa cells from PCOS patients compared to those from non-PCOS women. In contrast, transcript levels of one ZDHHC palmitoyltransferase, ZDHHC2, were observed to be decreased in granulosa cells isolated from the ovaries of women with PCOS compared to those from non-PCOS women. Since palmitoylation of GSDMD has been found to be required for its membrane translocation and oligomerization, the identification of palmitoyltransferases for GSDMD palmitoylation in granulosa cells might be of high clinical importance to limit pyroptotic death of granulosa cells and inflammation in PCOS. Since chronic low-grade inflammation is also observed in women with PCOS, palmitoyltransferase-targeting therapies might have potential to limit inflammation by supressing pro-inflammatory death of granulosa cells in the ovary.

Abstract

Metallophthalocyanines (MPcs) are 18-π electron macrocyclic structures composed of four isoindole units. Phthalocyanines (Pb) are used in many areas due to their stability, excellent electronic properties, architectural flexibility, chemical-physical properties and spectroscopic properties [1]. Initially utilized as dyes and pigments due to their distinctive blue-green hues, phthalocyanine compounds have evolved into significant entities extensively researched across various domains, including catalysis, liquid crystals, dye-sensitized solar cells, photocatalysis, energy storage, electrochemistry, gas sensors, optical data storage, supercapacitor electrode materials, enzyme inhibitors, and photodynamic cancer therapy, attributable to their exceptional thermal, physical, and chemical stability. [2] The interest for Pc-based materials lies in the fact that they are one of the most important π-conjugated molecules and many of their properties can be adjusted by different peripheral substituents introduction and changes of the central metal ion [3]. However, the limited solubility of phthalocyanines in water and organic solvents and their high tendency to aggregation are the most significant factors that reduce their applicability in these areas. In this study, non-peripheral octa-substituted Ni (II), Zn (II), and Cu (II) phthalocyanines were synthesized and their aggregation properties were investigated.

Keywords: Synthesis, octa phthalocyanine, non-aggregating

COVID-19'da IL6 ve TMPRSS11A polimorfizmlerinin genotip kombinasyonları ile hastalık şiddeti arasındaki bağlantı

Nilgün Çekin

Sivas Cumhuriyet Üniversitesi, Tıp Fakültesi, Tıbbi Biyoloji Anabilim Dalı, Sivas, Türkiye

Sorumlu yazar e-mail: nilgun_cekin@yahoo.com

Özet

COVID-19 hastalığının klinik seyri bireyler arasında büyük farklılıklar göstermektedir. Bu farklılıklarda genetik varyasyonların önemli rol oynadığı düşünülmektedir. IL6, proinflamatuvar sitokin yanıtını artırarak sitokin fırtınasına ve çoklu organ hasarına yol açabilmektedir; TMPRSS11A ise SARS-CoV-2'nin hücreye girişinde spike proteininin proteolitik aktivasyonu yoluyla hastalık şiddetini etkileyebilmektedir. Bu çalışmada, IL6 (rs1800795, rs1800796) ve TMPRSS11A (rs353163, rs977728) gen polimorfizmlerinin ve bunların genotip kombinasyonlarının Türk toplumunda COVID-19 şiddeti ve klinik parametrelerle ilişkisi araştırılmıştır. Çalışmaya 84 kontrol, 80 orta şiddette COVID-19 (MC-19) ve 168 şiddetli COVID-19 (SC-19) olgusu dahil edilmiştir. Genotipleme PCR-RFLP yöntemi ile yapılmış; dört polimorfizmin gruplar arası dağılımları ve genotip kombinasyon frekanslarının klinik parametrelerle olası ilişkileri analiz edilmiştir. Genotip kombinasyon analizlerinde, özellikle IL6 ve TMPRSS11A polimorfizmlerini birlikte taşıyan kombinasyonlarda (ör. GC/GC/TC/CT ve CC/CC/CC/CT), CRP >200 mg/L, Ferritin >600 ng/mL, hsTroponin >5000 ng/L ve D-dimer >6000 µg/L seviyelerine ulaşıldığı görülmüştür. Bu durum inflamasyon, koagülopati ve kardiyak komplikasyon riskinin genetik varyasyonlarla arttığını göstermektedir. IL6 ve TMPRSS11A polimorfizmleri ve bunların kombinasyonları, COVID-19 şiddetinin yanı sıra sistemik inflamasyon ve organ hasarını gösteren biyobelirteçlerle anlamlı ilişki göstermektedir. Bu bulgular, COVID-19 klinik seyrinde genetik belirteçlerin risk öngörüsü ve kişiselleştirilmiş tedavi yaklaşımlarında kullanılabileceğini desteklemektedir.

Anahtar Kelimeler: COVID-19, IL-6, TMPRSS11A, polimorfizm, genotip kombinasyonları, Türk popülasyonu

Özet

Bu çalışma, Mardin ilimizin tarihsel ve kültürel birikimi içerisinde yer alan, ancak zamanla unutulmaya yüz tutmuş geleneksel bir yemek olan Hupık yemeğinin tespit edilmesi, kayıt altına alınması ve gastronomi bilimine kazandırılması amacıyla gerçekleştirilmiştir. Mardin, birçok medeniyete ev sahipliği yapmış olması nedeniyle çok zengin bir mutfak kültürüne sahiptir. Ancak sözlü kültürle aktarılan bazı yemeklerin yazılı kaynaklarda yer almaması, bu değerlerin zamanla kaybolmasına neden olmaktadır. Bu çalışmanın ilk aşamasında Mardin'in Mazıdağı ilçesine bağlı Ulutaş Köyü ziyaret edilerek yerel halkla doğrudan temas kurulmuştur. Köy muhtarının desteğiyle, *Hupık* yemeğini bilen ve hazırlayan gönüllü katılımcılara ulaşılmıştır. Katılımcılar yemeğin üç farklı şekilde tüketildiğini belirtimişlerdir ve katılımcılardan alınan bilgiler ışığında yemeğin reçetesi oluşturulmuştur. Çalışmanın ikinci aşamasında ise Gastronomi ve Mutfak Sanatları Bölümü uygulama mutfağında ürünler tekrar üretilmiş olup duyusal analiz konusunda yarı eğitimli panelistlerin bulunduğu bir panelde değerlendirilmişlerdir. Mardin yöresine ait bir yemek olan Hupık yemeğini deneyen panelitsler ürünleri derecelendirilmiş bir skalada renk, görünüş, tat, koku ve genel beğeni açısından değerlendirmiştir. Bu çalışma kültürel mirasın korunması, gastronomi alanında sürdürülebilirlik sağlanması ve bu sürdürülebilirliğin gıda bilimi ile ilişkilendirilmiş olması açısından önem arz etmektedir.

Anahtar kelimeler: Mardin yemek kültürü, sürdürülebilirlik, duyusal değerlendirme

Özet

Bu olgu sunumunun materyalini Alman Çoban Köpeği ırkı gebe bir köpekte görülen tek yavru sendromuna bağlı olarak şekillenen güç doğum olgusu oluşturdu. Alınan anamnez bilgilerinde köpeğin 67 gün önce çiftleştiği ve kliniğimize başvurmadan bir gün önce koyu renkli, yoğun, kokusuz, damla damla şekilde bir vaginal akıntının geldiği ancak doğuma ilişkin herhangi bir belirtinin olmadığı öğrenildi. Yapılan fiziksel muayenelerde hayvanın genel durumunun iyi olduğu, tam kan sayımında nötrofili ve lenfopeni tespit edildi. Biyokimya parametrelerinde normal aralıklardaydı. Transabdominal ultrasonografik muayenede abdomende tek bir yavrunun olduğu, kalp atımının olmadığı ve yavru sularının azaldığı tespit edildi. Abdominal radyografik muayenelerde ise posterior prezentasyonda dorsalumbal pozisyonda olan tek bir fetüs tespit edildi. Olgunun köpeklerde riskli bir gebelik olarak sınıflandırılan tek yavru sendromu olduğu tespit edildi ve sezaryen operasyonuna karar verildi. Sezaryen operasyonu sonrası yavrunun ölü olduğu görüldü. Operasyon sonrası annede herhangi bir postoperatif komplikasyonla karşılaşılmadı. Sonuç olarak köpeklerde tek yavru sendromuna bağlı olarak güç doğum olgularının şekillenebileceği ve sezaryen opersayonlarının olgunun yönetiminde endike olduğu kanısına varıldı.

Anahtar Kelimeler: Köpek, tek yavru sendromu, güç doğum

Abstract

Although traditional wound dressings are widely used, they often suffer from drawbacks such as inadequate infection control and limited ability to promote healing, often leading to chronic inflammation. To overcome these limitations, bioactive films have emerged as promising multifunctional materials, suitable for applications in wound dressings, cosmetics, and dermatological products. These dressings can be formulated with diverse materials and bioactive agents that actively influence and enhance the wound-healing process. Among bioactive agents, plant derived therapeutics such as plant extracts are widely used in the development of bioactive films. Grape seed oil (GSO), abundant in unsaturated fatty acids, is widely recognized for its potent antioxidant, anti-inflammatory, moisturizing and acne healing abilities. The present study aims to produce bioactive polymeric films containing various concentrations of GSO (1-4 %) for potential wound dressing applications. The solvent casted bioactive films were subjected to FT-IR analysis, mechanical and antioxidant tests. The amount of GSO effected the physical and antioxidant properties of chitosan (CS)/sodium alginate (SA) films. As the GSO concentration in GSO/CS/SA films increased, the antioxidant capacity of the films also increased. Higher GSO concentration caused significantly reduced tensile strength ($p < 0.05$) compared to neat CS/SA film. Overall, the results proposed the grape seed oil incorporated films as encouraging bioactive wound dressing materials for accelerating the healing of skin wounds.

Keywords: Biocomposite films, grape seed oil, sodium alginate, chitosan, wound healing.

Özet

Son on yılda elektrokimyasal yöntemlerin geliştirilmesi ve teknolojik ilerlemeler sayesinde eş zamanlı elektrokimyasal tayin çalışmaları göze çarpmaktadır. Günümüzde bileşiklerin ayrı ayrı elektrokimyasal tayininin yerini, iki ya da daha fazla analitin birlikte tayin edildiği elektrokimyasal yöntemler almıştır [1]. Eş zamanlı tayin, biyolojik sıvılarda, dokularda ve çevrede bulunan hastalıkların, patojenlerin veya toksik maddelerin kısa sürede kapsamlı bir şekilde izlenmesine katkıda bulunabilmektedir. Eş zamanlı tayin, zaman ve maliyet açısından önemli avantajlar sağlamaktadır. Eş zamanlı tayinlerde optik ve voltametrik yöntemler kullanılmaktadır. Analitlerin eş zamanlı tayinleri için hızlı, pratik ve düşük maliyetleri nedeniyle sıklıkla elektrokimyasal yöntemler tercih edilmektedir [2]. Yüksek duyarlılık, düşük tespit sınırı, ön işlem gerektirmeyen doğrudan biyolojik örnek analizi ve kısa analiz süresi gibi özellikleri sayesinde voltametrik yöntemler (dönüşümlü voltametri, diferansiyel puls voltametri vd.), diğer elektroanalitik tekniklere göre öne çıkmaktadır [2]. Literatürde geliştirilen eş zamanlı elektrokimyasal sensörler, dopamin, serotonin, epinefrin ve norepinefrin gibi nörotransmiterlerin, ürik asit, askorbik asit, NADH gibi biyolojik numunelerde sıklıkla bulunan analitlerin ve katekol, o-kinon ve rezorsinol gibi zararlı kirleticilerin tayinine yöneliktir [1]. Bu çalışmada, çeşitli analitlerin eş zamanlı tespiti için geliştirilen elektrokimyasal sensörlerdeki son gelişmeler ele alınmıştır.

Anahtar kelimeler: Eş zamanlı tayin, elektrokimyasal sensör, voltametrik metotlar

Özet

Atıştırmalık gıda tüketimi günümüzde oldukça revaçtadır. Bu ürünler arasında cipsler büyük bir yer kaplamakta, özellikle patates ve mısır içeren cipsler çokça tercih edilmektedir. Bu çalışma, tüketicilerin tekdüze lezzetler yerine yeni ürünleri deneyimlemesi, bununla birlikte atıştırmalıklar arasına sağlıklı sayılabilecek özellikteki grupların eklenmesi düşüncesi ile tasarlanmıştır. Bilindiği üzere baklagiller arasında bulunan fasulye; proteinler, çeşitli vitamin ve mineraller açısından değerlidir. Çalışma kapsamında önerilen ürün formülasyonunda siyah, kırmızı ve beyaz (normal) fasulyeler ayrı ayrı gruplandırılarak haşlanmış ve her bir grup içerisine eşit miktarda zeytinyağı, tuz, sarımsak, toz kırmızı biber ve kekik eklenerek çeşnilendirilmiştir. Hazırlanan cips hamurları kalıp yardımıyla şekillendirilmiş ve fırın tepsisine aktarılmıştır. Ürün pişirme aşamasında fırınlama yöntemi tercih edilerek hazırlanan ürünlerin yağ içeriğinin değişmemesi hedeflenmiştir. Ürünlerin pişirilmesini takiben, yarı eğitimli panelistlerin olduğu bir panel grubu ile ürünlerin duyusal özellikleri görünüm, doku, aroma, koku ve genel beğeni açısından değerlendirilmiştir. Tüketici testlerinde fasulyenin cips üretiminde iyi bir alternatif olabileceği, farklı baharatlar ile istenen cips aromasının oluşturulabileceği, böylelikle sağlıklı atıştırmalıklar kategorisine yeni bir ürün ilave edilebileceği görülmüştür.

Anahtar kelimeler: Fasulye cipsi, fonksiyonel gıda, duyusal değerlendirme

Abstract

Cadmium **(**Cd^{2+}) is a potentially toxic element, and its compounds cause various disruptions to human health and ecosystems. It has been reported that Cd^{2+} causes bioaccumulation by entering living metabolism through various environmental pathways and the food chain. Therefore, the determination of Cd^{2+} with high accuracy in these matrices for human consumption is of great importance. On the other hand, the interference effects from the matrix cause a significant limitation on the accuracy of the measurement results. In this study, Cd^{2+} was determined in sage and rosehip samples with high accuracy and sensitivity by flame atomic absorption spectrometry (FAAS) using different calibration techniques. The analytical performance values such as limit of detection, limit of quantitation, dynamic linear range, regression coefficient and percent relative standard deviation were assessed under optimal operating conditions with aqueous Cd^{2+} solutions at varying concentrations. Recovery studies were performed on sage and rosehip tea matrices to verify the reliability of the FAAS measurements. The recoveries were recorded between 96.5% and 101.9% for sage tea and between 97.6% and 101.0% for rosehip tea utilizing the matrix matching calibration. It was demonstrated that the proposed analytical approaches can be applied to the determination of Cd^{2+} with high accuracy in herbal teas frequently consumed in daily life, as well as to obtain reliable results in routine food analysis.

Keywords: Herbal tea, flame atomic absorption spectrometry, cadmium

Abstract

There are a limited number of studies on the use of protein-based films containing different oil blends, particularly in the biomedical field as wound dressing materials. Therefore, this study aims to investigate the effects of St. John's Wort oil (JWO) on the material properties of gelatin-based films containing coconut oil (CO) for potential wound dressing applications. For this purpose, equal percentages of JWO and CO were incorporated into the film-forming solution of gelatin. Homogeneous and transparent films were obtained using the solution casting method. Structural changes were observed by Fourier Transform Infrared Spectroscopy (FTIR), indicating the presence of fatty acids from CO and JWO in the gelatin matrix, with an increased peak amplitude at 1740 cm^{-1}. Moreover, the amplitude of the peak at 2853 cm^{-1}, related to C–H stretching, decreased in films containing JWO. Scanning Electron Microscopy (SEM) analyses revealed embedded oil droplets on the surface of the blended films. Differential Scanning Calorimetry (DSC) analyses showed that the addition of JWO increased the glass transition temperature from 72°C to 75°C, thereby improving the thermal properties of the gelatin films. Water aging behaviour of the gelatin films containing oil blends also improved by more than 8%. This study demonstrates that CO and JWO blends can be successfully incorporated into gelatin matrices, which can be further developed into low-cost, durable, thermally stable primary wound dressing materials for acute wounds using natural ingredients.

Keywords: St. John's Wort oil, Coconut oil, Gelatin, Biomedical, Structural, Thermal.

Abstract

Synthetic insecticides have long been used to manage major agricultural pests. However, increasing public concern over the potential environmental risks associated with the extensive use of conventional insecticides has prompted the search for alternative pest control strategies. Essential oils derived from aromatic plants are considered promising alternatives due to their diverse biological activities, biodegradability, and minimal impact on non-target organisms and the environment. In this study, the essential oil of *Clinopodium serpyllifolium* subsp. *serpyllifolium* was extracted using a solvent-free microwave extraction method, and its chemical composition was analyzed by GC–MS. The fumigant toxicity of the essential oil was evaluated against different larval stages of *Tenebrio molitor*. Five concentrations (2, 4, 8, 16, and 32 µL/L) of the essential oil were tested for toxicity. For each larval stage tested, the mortality rate increased with higher concentrations. Early larval stage was more susceptible compared to the medium and late larval stages. Based on Probit analysis, the LC_{50} value for the early larval stage was determined to be 6.59 µL/L, while for the medium and late larval stages, it was 12.48 µL/L and 18.84 µL/L, respectively. The results indicate that the essential oil exhibits fumigant toxicity against *T. molitor* larvae, with higher efficacy particularly at the early larval stages. Therefore, targeting the early larval instars of the pest may lead to more effective control.

Keywords: Essential oil, Aromatic plant, Solvent-free microwave extraction, GC–MS, *Tenebrio molitor*, Fumigant toxicity

Abstract

Aging is a multifactorial biological process strongly associated with oxidative stress, which results from an imbalance between the generation of reactive oxygen species and the antioxidant defense system. This imbalance contributes to lipid peroxidation, protein oxidation, and depletion of endogenous antioxidants, thereby promoting structural and functional deterioration in vital organs such as the liver and kidney. In this study, we investigated the potential protective and therapeutic effects of squalene (SQ) and saponin (SP), administered individually and in combination, in a D-galactose-induced aging model. Forty-eight male Sprague-Dawley rats were randomly assigned to control, D-galactose, SQ, SP, and combination groups. Aging was induced by intraperitoneal injection of D-galactose (300 mg/kg/day) for six weeks, and SQ (2.66 mL/kg/day) and SP (100 mg/kg/day) were administered orally, either alone or together. At the end of the experimental period, liver and kidney tissues were collected, and malondialdehyde (MDA), a biomarker of lipid peroxidation, and glutathione (GSH), a central antioxidant molecule, were measured spectrophotometrically. D-galactose administration significantly increased MDA levels and decreased GSH concentrations in both liver and kidney tissues compared to controls ($p<0.05$). Treatment with either SQ or SP reversed these alterations, while the combined administration demonstrated the most pronounced reduction in MDA and elevation in GSH levels, indicating a synergistic antioxidant effect. The results suggest that oxidative stress plays a central role in aging-related hepatic and renal dysfunction, and that supplementation with SQ and SP may enhance antioxidant defense and mitigate oxidative damage. Importantly, the combined treatment was more effective than individual applications, supporting the potential of SQ and SP as complementary agents in strategies aiming to attenuate oxidative stress-associated aging processes.

Abstract

Tobacco (*Nicotiana tabacum* L.), belonging to the *Solanaceae* family, is widely cultivated for the production of nicotine-containing products. Moreover, tobacco is a model organism for molecular biology and genetics due to its well-characterized genome and high transformation efficiency. Tobacco production is severely threatened by various fungal and oomycete pathogens, which can lead to substantial yield and quality losses. Among these, black shank caused by *Phytophthora nicotianae*, and powdery mildew caused by *Golovinomyces cichoracearum* or *Erysiphe cichoracearum* are two of the most destructive diseases affecting tobacco worldwide. MicroRNAs (miRNAs) with 20-24 nucleotides in length are important post-transcriptional gene expression regulators. In this study, novel miRNAs found in tobacco genome targeting powdery mildew and black shank were identified by using *in silico* analyses. For this purpose, reference miRNAs were obtained from mirBase database and they were blasted against tobacco genome (taxid: 4097) in NCBI. Then, the secondary stem-loop hairpin structures of the potential target miRNAs were constructed by using RNAfold Web Server. The RNAhybid program was used to identify miRNAs targeting a total of 65 genes related to black shank disease (rps10, nad9, rns, tRNA-Met3(cat), tRNA-Asn(gtt), atp8, etc.) and even a gene (AXI65_gp1) responsible for powdery mildew disease. As a result, we determined 76 novel miRNAs for black shank and 15 novel miRNAs for powdery mildew. This study provides valuable information for the production of resistant tobacco plants as well as a promising new viewpoint on tobacco miRNAs that target powdery mildew and black shank.

Özet

Cuscuta epithymum Murr. (*C. epithymum*) Convolvulaceae familyasına ait holoparazit bir bitkidir; Fars tıbbında Aftimoon olarak bilinir. Ayrıca delilik ilacı anlamına gelen Dava Aljonoon olarak da adlandırılır, ancak yaygın olarak Dodder veya Kekik dodder olarak bilinir. Çalışmamızda Balıkesir'in yüksek yerlerinden toplanan *C. epithymum* topraküstü kısımlarından soxhlet aparatı yardımıyla elde edilen etanol ekstresinin fenolik bileşenleri ise HPLC-DAD cihazı yardımıyla belirlendi. Uygulanan fenolik metodunda 41 adet fenolik standart madde ile kıyaslaması yapılarak tespit edilen bileşenlerin konsantrasyonları hesaplandı. *C. epithymum*'dan alınacak olan farklı etanol ekstresinin DPPH, ABTS, CUPRAC ve β- Karoten linoleik asit deneyleri olmak üzere 4 farklı metot ile antioksidan aktiviteleri Elisa reader cihazı yardımıyla belirlendi. Aktivite sonuçları karşılaştırılıp konsantrasyonları hesaplandı. Bu çalışmanın amacı, Türkiye'de sebze olarak tüketilen yabani yenilebilir *C. epithymum* etanol ekstresinin fenolik içeriklerini ve antioksidan aktivitelerini değerlendirmektir. Elde edilen ekstrelerin fenolik içerikleri 4 farklı metot ile antioksidan kapasiteleri hesaplandı. Antikolinesteraz, α-Amilaz ve α-Glukosidaz enzim inhibisyon aktiviteleri belirlendi. Yapmış olduğumuz çalışmalardan elde etmiş olduğumuz sonuçlar neticesinde ileriki safhada kromatografik olarak yapılacak olan izolasyon çalışmalarının ve sitotoksik aktivite çalışmalarının yapılması için altyapı oluşturacaktır.

Anahtar Kelimeler: *Cuscuta epithymum*, Fenolik içerik, Antioksidan aktivite, Enzim inhibisyon aktivite.

Abstract

Anastatica hierochuntica, commonly known as the resurrection plant or Rose of Jericho, is a desert species renowned for its remarkable tolerance to extreme abiotic stress conditions, such as drought, salinity, and high temperature. In addition to being rich in bioactive compounds, including flavonoids and phenolics, *A. hierochuntica* demonstrates significant antioxidant, antimicrobial, and antiinflammatory properties. Recent studies have highlighted its potential applications in agriculture as a natural biostimulant and in medicine as a source of novel therapeutic agents. In this study, we investigated the phenolic, flavonoid, and antioxidant activity (IC50) of *A. hierochuntica*. Three solvents (50% ethanol, 50% methanol, and 50% isopropanol) were used for extraction. Then, the Folin-Ciocalteu method, $AlCI_3$, and DPPH methods were used for analyses, respectively. The experiment was repeated three times. Ethanol extracts showed that total phenolic content was 43.546 ± 10.556 mgGAE/g, the flavonoid content was 3.248 ± 0.602 mgQE/g, and the antioxidant activity was 2.739 mgVCE/100g. We also determined that the total phenolic content was calculated as 27.369 ± 4.567 mgGAE/g, the flavonoid content as 1.002 ± 0.555 mgQE/g, and the antioxidant activity as 1.418 mgVCE/100g in methanol extracts. Moreover, these concentrations were 58.277 ± 19.909 mgGAE/g, 4.556 ± 0.853 mgQE/g, and 3.306 mgVCE/100g, respectively, in isopropanol extracts. Our findings can advance knowledge of this plant's bioactive profile and possible uses in the future, particularly in antibacterial and agricultural research.

Abstract

In this study, RuCo-decorated poly(2-hydroxy methacrylamide) [p(2-HMAAm)] polymer brush grafted magnetic nanoparticles were synthesized and evaluated as a heterogeneous catalyst for the degradation of some azo dyes. The nanocomposite was prepared through a surface-initiated polymerization technique, followed by the immobilization of bimetallic Ru and Co nanoparticles onto the magnetic polymer support. Structural and morphological analyses confirmed the successful formation of the polymer-coated magnetic core and the uniform distribution of metal nanoparticles. The catalytic activity of RuCo/p(2-HMAAm)/Fe_3O_4 was examined for the reduction of representative azo dyes in aqueous media under mild conditions. The reaction followed pseudo-first-order kinetics, showing high catalytic efficiency compared with similar catalysts reported in the literature. The improved performance was attributed to the synergistic interaction between Ru and Co nanoparticles and the high accessibility of active sites provided by the polymer brush structure. Additionally, the catalyst exhibited excellent magnetic recoverability and could be reused several times without significant loss of activity, indicating strong structural stability and recyclability. These results demonstrate that the RuCo/p(2-HMAAm)/Fe_3O_4 nanocomposite is an efficient, magnetically separable, and environmentally friendly catalyst for the degradation of azo dyes and the purification of dye-contaminated wastewater.

Abstract

In recent years, drug research has aimed to minimize the dosage and toxicity of cancer drugs while ensuring targeted drug delivery. To achieve this, pharmaceutical nanotechnology has gained importance, particularly in the application of anticancer drugs with polymeric encapsulations. Selecting a compatible polymeric carrier is pivotal for stable loading and controlled release of small-molecule therapeutics. In this study, a rapid, materials-oriented ***in silico*** workflow is presented to prescreen polymer–drug compatibility for Queuine and Gemcitabine**.** Amorphous cells of carriers (PEG, PGA, PLA, PLGA) and drug–polymer systems were simulated by 100 ns MD simulations to extract bulk descriptors such as Hildebrand solubility parameter**,** cohesive energy**,** and density**.** Based on these parameters, PGA and PLGA showed the smallest mismatch to both drugs, indicating favorable mixing behavior aligned with prior knowledge. This fast, reproducible computational workflow supports rational carrier selection before experimental formulation, helping boost success rates and reduce costs.

Abstract

Poly(vinyl alcohol) (PVA) is a water-soluble and biodegradable polymer that has been widely utilized in biomedical, pharmaceutical, packaging, and environmental applications due to its good film-forming ability, chemical stability, biocompatibility, and non-toxicity. However, its high hydrophilicity and inadequate mechanical stability limit its usage in various applications. To overcome these drawbacks, crosslinking techniques are often employed to improve the structural integrity and stability of PVA-based materials. In this study, a PVA- based film was developed using tannic acid (TA), a naturally occurring, non-cytotoxic polyphenol, as a sustainable alternative to synthetic crosslinkers. The incorporation of TA as a natural crosslinking agent improved the functional performance of PVA films without relying on conventional chemical crosslinkers. TA molecules, with its abundant phenolic hydroxyl and catechol groups, interacts with PVA chains through hydrogen bonding and esterification reactions, forming a mechanically reinforced polymeric network. Fourier Transform Infrared Spectroscopy (FTIR) analysis confirmed the crosslinking interaction by showing a change in the –OH stretching band and the appearance of characteristic C=O absorption peaks. Mechanical characterization showed that TA incorporation increased tensile strength and slightly reduced elongation, indicating enhanced stiffness due to crosslinking. Water contact angle (WCA) measurements revealed a slight increase in hydrophobicity with increasing TA concentration, attributed to the reduced availability of free hydroxyl groups within the PVA matrix. Overall, the incorporation of tannic acid into PVA films provides a green crosslinking approach that enhances mechanical strength, structural integrity, and water resistance, demonstrating strong potential for use in biomedical and advanced packaging applications.

Abstract

Research and development in green chemistry have gained considerable attention in recent years due to their potential to provide efficient, clean, cost-effective, and environmentally friendly processes that minimize toxic by-products. Within this framework, plant seed extracts have emerged as promising alternatives to conventional chemical stabilizing and reducing agents, particularly in nanoparticle synthesis, offering single-step, sustainable, and eco-friendly production routes. Seeds possess advantages such as low maintenance cost, independence from growth conditions, and rich bioactive compositions, enabling them to function effectively as both reducing and capping agents. In this study, zinc oxide nanoparticles (ZnO-NPs) were biosynthesized using an extract obtained from hawthorn (*Crataegus monogyna*) seeds, which are generally considered agro-waste in the food and herbal product industries. The synthesis process was optimized by adjusting parameters including precursor concentration, extract ratio, reaction temperature, pH, and time to achieve maximum nanoparticle yield and stability. Comprehensive characterization was performed using UV–Vis spectroscopy, X-ray diffraction (XRD), Fourier-transform infrared spectroscopy (FTIR), scanning electron microscopy with energy-dispersive X-ray analysis (SEM–EDX), dynamic light scattering (DLS), and zeta potential measurements. The formation of ZnO-NPs was confirmed by a visible color change and a characteristic UV–Vis absorption peak at 345 nm. SEM analysis revealed nearly spherical particles with sizes ranging from 22.01 to 26.28 nm, while FTIR spectra identified functional groups responsible for reduction and stabilization. The zeta potential (−18.5 ± 1.41 mV) indicated moderate colloidal stability. The photocatalytic performance of the ZnO-NPs was evaluated by the degradation of methylene blue (MB) under solar irradiation, achieving 82.4% degradation within 180 minutes. The nanoparticles retained notable activity after five reuse cycles, confirming their stability and reusability. Overall, the findings demonstrate that agro-waste-derived hawthorn seed extract can serve as a sustainable, low-cost, and eco-friendly green reducing agent for the green synthesis of ZnO nanoparticles with excellent photocatalytic efficiency for environmental remediation.

Keywords: Green chemistry, agro-waste, *Crataegus monogyna*, zinc oxide nanoparticles, photocatalytic degradation.

Abstract

Approximately 172 mammal species have been recorded from Anatolia so far, 72 of which belong to Order: Rodentia. The systematics and phylogenetic relationships of these rodent species have been studied for many years using morphological, karyological, and molecular (mitochondrial and nuclear gene region analyses) methods, but the taxonomic status of many taxa remains unclear. Therefore, the need for new methods that provide more practical and reliable results has increased. In recent years, complete mitochondrial gene sequences of species have begun to be obtained, but the mitogenome sequences of many species have not yet been provided. The present study represents the complete mitochondrial DNA sequencing of Turkish Hamster (*Mesocricetus brandti* Nehring 1889) for the first time. The 16384 base pair data was obtained and it comprises of 13 protein coding genes, 22 tRNA genes, 2 rRNA genes, and D-loop (control) region, and most gene regions are coded on the heavy strand. Also, AT content (57.31%) was higher than GC content (42.69%). Phylogenetic analyses were conducted adding the available sequences of some species of the subfamily Cricetinae and it was observed that *M. brandti* was located closely with other *Mesocricetus* species (*Mesocricetus auratus*).

Keywords: DNA, hamster, *Mesocricetus*, mitogenome

Özet

İşitme kaybı bulunan bireylerde doğru hoparlör seçimi, işitme cihazı uyumunun başarısı ve kullanıcı memnuniyeti açısından kritik öneme sahiptir. Geleneksel seçim yöntemleri büyük ölçüde odyoloğun deneyimine dayanmakta, bu da öznellik ve hata payını artırabilmektedir. Amaç: Bu çalışmanın amacı, makine öğrenmesi algoritmaları ile bireylerin odyolojik verilerinden en uygun hoparlör tipini otomatik olarak belirlemenin uygulanabilirliğini incelemektir. Materyal ve Yöntem: 2018–2023 yılları arasında işitme cihazı merkezine başvuran, 35–65 yaş aralığında sensörinöral işitme kaybı bulunan 450 bireyin retrospektif verileri analiz edilmiştir. Veri setinde yaş, cinsiyet, saf ses odyometri eşikleri (125–8000 Hz), hava ve kemik yolu saf ses ortalaması değerleri, konuşmayı alma eşiği ve konuşmayı ayırt etme parametreleri yer almıştır. Hoparlör tipleri sınıflandırma hedefi olarak beş sınıf (S, M, P, HP, SP) şeklinde belirlenmiştir. Python ortamında Random Forest algoritması uygulanmış, veri seti %70 eğitim, %30 test olarak ayrılmış, 5-katlı çapraz doğrulama ile aşırı öğrenme engellenmiştir. Model performansı doğruluk, kesinlik, geri çağırma, F1 skoru ve ROC-AUC metrikleri ile değerlendirilmiştir. Bulgular: Random Forest algoritması ile sol kulakta %85.7 train doğruluğu, %84.7 test doğruluğu; sağ kulakta ise %77.5 train doğruluğu, %77.0 test doğruluğu elde edilmiştir. Sol kulakta Precision %85, Recall %85, F1 %84; sağ kulakta Precision %75, Recall %77, F1 %75 bulunmuştur. ROC-AUC değerleri, sol kulakta yüksek, sağ kulakta kabul edilebilir düzeyde ayrıştırma gücü göstermiştir. Özellik önem sıralamasında hava yolu saf ses ortalaması, kemik yolu eşiği ve konuşmayı alma eşiği öne çıkan parametreler olmuştur. Sonuç: Bulgular, odyologların deneyime dayalı öznellikten bağımsız daha hızlı ve doğru hoparlör seçimi yapmasına imkân tanıyabilir. Gelecek çalışmalar için farklı algoritmalar, parametre optimizasyonları, daha büyük ve çok merkezli veri setleri ile karşılaştırmalı analizlerinin yapılması önerilmektedir.

Abstract

In this study, 120 traditional cheeses obtained without the use of starter cultures from markets and bazaars in Ankara were used. Suspicious colony morphology for *Enterococcus* was observed in 98 out of 120 traditional cheeses. Antimicrobial activity was detected by agar spot. Antimicrobial activities of 98 isolates were tested against *Salmonella* enterica sero type typhimurium SL 1344, *S. aureus* ATCC 6538, *L. monocytogenes* ATCC 7644 and *E. coli* ATCC 25922. Antimicrobial activity of 75 isolates was determined to have against pathogen bacteria. None of the 75 isolates indicated antimicrobial activity against *Salmonella* enterica sero type typhimurium SL 1344. Among them 69 isolates showed antibacterial inhibition zones ranging from 06-23 mm against *S.aureus*. Twenty-one isolates antibacterial inhibition zones ranging from 05-20 mm against *L. monocytogenes*, while 63 isolates antibacterial inhibition zones ranging from 06-21 mm against *E. coli*. Well diffusion assay was applied to determine the protein nature of the strains showing antimicrobial activity. Five of isolates with antimicrobial activity have been found to produce bacteriocins. All of the bacteriocin-producing isolates showed antimicrobial activity against *L. monocytogenes*. As a result of 16S rDNA sequence analysis, 2 of the 5 enterococci strains were identified as *E. faecium,* 2 as *E. faecalis,* and 1 as *E. lactis.*

Abstract

Since its introduction via the Suez Canal, the Lessepsian fish species Randall's threadfin bream *Nemipterus randalli* has successfully spread throughout the eastern Mediterranean, establishing dense populations and coexisting with the native sparid fish species common pandora *Pagellus erythrinus*. Understanding the trophic interactions between these species is crucial for assessing the ecological impacts of Lessepsian invasions on native fish communities. In this study, we used $\delta^{13}C$ and $\delta^{15}N$ stable isotope analyses to investigate trophic niches and resource overlap between the two species. Individuals were sampled during summer and winter at three locations in Gökova Bay (Aegean Sea), characterized by different fishing pressures: a no-fishing control zone and two actively fished areas. Isotopic analyses revealed spatial and seasonal variation in the trophic structure of the two investigated species. Specifically, *P. erythrinus* displayed slightly higher $\delta^{15}N$ values, suggesting a marginally higher trophic position, while *N. randalli* had more depleted $\delta^{13}C$ values, indicating differences in basal carbon sources and feeding habits. Isotopic overlap was more evident in fished areas, whereas the control zone displayed clearer separation in summer and more pronounced overlap in winter, suggesting dynamic resource use and higher competition under reduced prey availability. These findings are in line with the results of previous studies based on stomach content analyses, which reported high dietary overlap between the two species, supporting the idea that *N. randalli* can use similar food resources as native demersal fish. Altogether, our results highlight the trophic plasticity of *N. randalli* and demonstrate the value of stable isotope analysis in revealing feeding relationships and resource overlap between native and non-native species.

Abstract

The demand for the preparation of fluorescence materials, which form the basis of important application areas such as bio-imaging, organic solid-state lasers, and organic light-emitting diodes (OLEDs), is increasing day by day. Therefore, the design of suitable organic, inorganic or hybrid materials to be used in these application fields and to examine their activities have become very important. Cyclotriphosphazenes represent an important class of inorganic heterocyclic compounds that can be functionalized with suitable organic groups to form inorganic-organic hybrid systems possessing tailored properties. The versatile reactivity of the phosphorus-halogen bonds within the cyclotriphosphazene ring allows the formation of diverse substitution patterns with various functional groups, which plays a crucial role in designing compounds exhibiting distinct photophysical characteristics. Therefore, in this study, inorganic-organic hybrid compounds were designed and synthesized through the replacement reactions of di- and tetra- aniline substituted cyclotriphosphazenes with the carbazole group. As a result of these reactions, cyclotriphosphazene derivatives including two carbazole units (3a), three carbazole units (4b), and four carbazole units (5b), which may show different photophysical properties, were obtained. After the structural analysis and characterization of the compounds (3a, 4b and 5b) by various spectroscopic techniques were completed, their photophysical behaviors were examined via EEM analysis, steady-state fluorescence, UV-vis absorption, time-resolved fluorescence, and 3D-fluorescence spectroscopies to comprehend the effect of carbazole units substituted to cyclotriphosphazene derivatives. The compounds (3a, 4b and 5b) are the first examples of cyclotriphosphazenes bearing both aniline groups and carbazole units.

Abstract

Soil contains many microorganisms. These microorganisms form the microbiological structure of the soil. *Fusarium* fungi, which belong to this class of microorganisms, cause disease in many crops. In this study, were determined the pathogenicity and virulence of *Fusarium* species affecting sugar beet. Sugar beet an industrial agricultural product and one of the most important crops grown globally and in our country. In the study, sugar beet production areas in Suluova district of Amasya province were surveyed, and soil samples were taken from around the roots of 20 sugar beets showing root rot. Fungal isolation from the soil was performed on PDA medium. Thirty *Fusarium* isolates were isolated from soil samples. The identification of Fusarium species was performed based on microscopic analysis.In the pathogenicity test conducted on sugar beet, 18 fungal isolates(60%) caused rot. In the evaluation of rot diameters, 10 *Fusarium* isolates causing rot between 4-5 cm were found to be highly virulent, 6 *Fusarium* isolates causing rot between 3-4 cm were found to be moderately pathogenic, and 2 *Fusarium* isolates causing rot between 1-2 cm were found to be low in virulence. This study revealed that *Fusarium* species found in soil microorganisms include both pathogenic and non-pathogenic strains. It was determined that the virulence of pathogenic *Fusarium* species varies due to their genetic structure. In the continuation of the study, the isolated fungal species can be identified by species and their control can be investigated.

Keywords: soil microorganisms, *Fusarium* spp., sugar beet, pathogenicity, virulence

Abstract

Breast cancer is the most diagnosed malignant tumor in women and ranks first among the causes of death resulting from malignant neoplasms. Although significant progress has been made in breast cancer treatment in recent years, the current therapeutic approaches still fail to provide fully satisfactory outcomes. Therefore, new treatment strategies need to be explored (1). Photodynamic therapy (PDT) has emerged in recent years as a minimally invasive therapeutic method that has attracted great interest as a novel cancer treatment. PDT utilizes photosensitizers that, upon activation by light of a specific wavelength, react with molecular oxygen in the target tissue to generate reactive oxygen species (ROS), leading to cell death. ROS induce damage to tumor cell membranes, proteins, and DNA, ultimately resulting in cell death. PDT is considered a promising therapeutic approach, particularly for superficial and localized cancers such as breast cancer. Compared to conventional therapeutic methods, PDT offers higher tumor selectivity due to the preferential localization of photosensitizers within tumor lesions and the precise irradiation of these regions with light (2). The aim of this study is to investigate the photostability, DNA interactions, and *in vitro* PDT efficacy of water-soluble silicon (IV) phthalocyanine compounds containing pyridine substituents (3PY-7a-SiQ and 3PY-8a-SiQ) in MCF-7 (human breast adenocarcinoma, ATCC, HTB-22 ™) and MCF-10A (human breast epithelial cell, ATCC, CRL-10317 ™) cell lines. This study has been granted by Acibadem Mehmet Ali Aydinlar University Scientific Research Projects Coordination Unit under grant number TSA-2025-2261.

Abstract

Although drug trafficking may evoke criminal cases, contact with these substances, whether intentional or unintentional, can lead to medical problems. In particular, swallowing these substances at the moment to avoid detection, or swallowing them wrapped in casings for transportation purposes, may be asymptomatic; however, if the casings tear or puncture, overexposure can cause numerous adverse respiratory, neurological, and cardiac effects, and even mortality. A 41-year-old male identified as a drug carrier was brought to the hospital emergency room by security guards. The patient was conscious, with no vital sign abnormalities and hemodynamically stable. A contrast-enhanced abdominal tomography (CT) was performed. The tomography revealed multiple smooth oval hypodense contents and thin hyperdense walls throughout the stomach and small and large bowel lumen. The findings were consistent with swallowed capsule packets. As the capsules were filled with heroin and there was a risk of rupture during procedures such as endoscopic removal, which could lead to the absorption of a lethal dose of opioids, the patient was admitted to intensive care without any procedures being planned. The spontaneous defecation of the capsules was monitored, and 84 of the 85 capsules identified as swallowed were passed in the stool and handed over to security personnel. Even if patients are asymptomatic, radiological imaging is necessary. CT scans are both sensitive and highly reliable in detecting capsules. Once capsules are detected, emergency endoscopic or colonoscopic interventions can cause more harm than good. Rupture of the capsules or casings can lead to excessive amounts of drugs entering the bloodstream and death. Spontaneous expulsion of the capsules through defecation can be expected in stable cases. In cases where the capsules do not pass, endoscopic and surgical interventions should always be considered and performed without delay when symptoms of ileus, perforation, acute abdomen, and intoxication develop.

Experimental and theoretical investigations of semi-lethal dose (D_{50}) values for bacterial population

Mürsel Şen[1*] (ORCID: https://orcid.org/0000-0002-0637-8325)

[*1]National Defence University, Turkish Air Force Academy, Department of Basic Sciences, İstanbul, Türkiye.

*Corresponding author e-mail: senmursel@hotmail.com; mursel.sen@msu.edu.tr

Abstract

The semi-lethal dose (D_{50}) is a parameter used to determine the sensitivity of microorganisms or cells to radiation. It is defined as the radiation dose that reduces the cell and bacterial population by half. D_{50} is obtained using the linear model (single-target single-hit model), which is the simplest mathematical model used to explain cell or bacterial death. The linear model is expressed as a first-order differential equation in the form $\frac{dN(D)}{dD} = -kN(D)$, where N(D) represents the number of surviving cells or bacteria as a function of radiation dose D, and k is the proportionality constant. The constant k is 1/ D_0, where D_0 is defined as the mean-lethal dose. Using the standard linear model, the standard theoretical D_{50} is given by $D_{50}=\ln 2/k= D_0 \ln 2$. In this study, the effects of different types of radiation (X-rays, gamma rays, and neutron particles) on Bact. Coli bacteria were investigated. Experimental D_{50} values, which representing the radiation dose that reduce the bacterial population by half for each type of radiation, were determined and compared with the standard theoretical D_{50} values obtained from the standard linear model. An inconsistency was observed between the experimental and standard theoretical D_{50} values. To eliminate this inconsistency, the standard linear model reconsidered and solved using the Caputo fractional derivative. The results showed that the experimental and fractional theoretical D_{50} values are consistent for the appropriate orders of fractional derivatives.

Keywords: Semi-lethal radiation dose (D_{50}), Linear model, Single-target single-hit model, Caputo fractional derivative, Mittag-Leffler function

Özet

Su ürünleri sektörü, son 50 yılda hızlı bir gelişme göstererek uluslararası ticarette önemli bir paya sahip olmuştur. Su ürünlerinin üretimi ve pazarlanmasının önemi kadar raf ömrü de ekonomik açıdan çok büyük önem taşımaktadır. Bu çalışmada, yenen doğal bir mantar olan ve halk arasında "çıntar" olarak bilinen *Lactarius deliciosus* (L.) Gray türünün özütlerinin 4 °C'de depolanan gökkuşağı alabalığı (*Oncorhynchus mykiss*) filetolarının raf ömrünü uzatmadaki antioksidan potansiyeli araştırılmıştır. Bu amaçla, *L. deliciosus*'tan etanol, metanol ve sıcak su özütleri hazırlanarak 300 ppm dozunda balık filetolarına uygulanmış; işlem görmemiş örnekler kontrol grubu olarak değerlendirilmiştir. Lipid oksidasyonu düzeyleri, tiyobarbitürik asit reaktif maddeler (TBA-RS) yöntemi kullanılarak belirlenmiş ve malondialdehit (MDA) değerleri 15 günlük depolama süresince belli periyotlarda, 532 nm dalga boyunda spektrofotometrik olarak ölçülmüştür. Elde edilen bulgular, mantar özütüyle muamele edilen filetoların kontrol grubuna kıyasla anlamlı derecede daha düşük MDA oluşumu gösterdiğini ortaya koymuştur ($p < 0.05$). On beşinci gün sonunda ortalama MDA değerleri kontrol örneklerinde 5.07 µM, etanol uygulanan örneklerde 4.46 µM, metanol uygulanan örneklerde ise yalnızca 1.30 µM olarak saptanmıştır. İstatistiksel analizler (ANOVA ve Tukey post-hoc testleri), özellikle metanol bazlı özütlerin depolama süresi boyunca lipid peroksidasyonunu en yüksek düzeyde baskıladığını göstermiştir. Bu sonuçlar, *L. deliciosus*'tan elde edilen doğal özütlerin, özellikle metanol bazlı olanların, oksidatif bozulmayı geciktirmede ve ürün kalitesini korumada etkili olabileceğini göstermiştir. Bu çalışmada elde edilen sonuçlar, doğal biyoaktif bileşiklerin sentetik antioksidanlara güvenli ve çevre dostu bir alternatif oluşturabileceğini göstermektedir. Günümüzde sürdürülebilir gıda koruma yöntemlerine yönelik artan ilgi dikkate alındığında, bu tür doğal özütlerin kullanımı hem ürün kalitesinin korunması hem de tüketici sağlığının desteklenmesi açısından önemli bir potansiyele sahiptir. Bununla birlikte, yöntemin endüstriyel ölçekte uygulanabilirliğini artırmak için, farklı balık türleri ve gıda sistemlerinde optimum özüt konsantrasyonlarının belirlenmesine yönelik ileri araştırmalara ihtiyaç duyulmaktadır.

Anahtar Kelimeler: çıntar, malondialdehit, doğal özüt, lipid oksidasyonu, tiyobarbitürik asit.

Abstract

Milk kefir (MK), a refreshing beverage with strong acidity and small amounts of alcohol and carbon dioxide, is produced by fermenting milk with MK grains. The grain microflora consisted of a complex symbiotic community of diverse lactic acid bacteria, yeasts, and acetic acid bacteria embedded in a polysaccharide matrix known as kefiran. This study aims to elucidate and compare the yeast flora of kefir grains (KGs) from various origins using molecular methods. This study used three distinct types of fresh KGs: goat-based (GK), cow-based (CK), and sheep-based (SK). Fermentations were performed at 28°C for 48 h using UHT sterilized milk in sterilized 1 L glass bottles inoculated with 3 g grain. Total yeasts and non-*Saccharomyces* yeasts were enumerated, isolated, and purified on PDA and Lysine media, respectively, at the start and end of the fermentation. Molecular identification of a total of 60 isolates was achieved by a combination of PCR-RFLP of the 5.8 S rRNA region and sequencing of the D1/D2 domain of the 26 S rRNA gene. Hae III, Hinf I and Cfo I restriction endonucleases selected as to differentiate of the 5.8S rRNA PCR product. The number of total yeasts (3.52-3.83 log cfu/mL to 8.14-8.62 log cfu/mL) and non-*Saccharomyces* yeasts (3.00-3.38 log cfu/mL to 6.74-8.41 log cfu/mL) increased significantly between the start and finish of the fermentation. Although the number of yeast species varied, *Saccharomyces cerevisiae* (*S.c.*), *Kazachstania unispora* (*K.u.*), and *Kluyveromyces marxianus* (*K.m.*) were isolated from all kefir beverages fermented with three distinct KGs. The frequencies of *S.c.*, *K.u.*, and *K.m.* were 52.94%, 41.18%, and 5.88% for kefir beverage fermented with CK grain; 15.79%, 63.16%, and 21.05% for beverage fermented with GK grain; and 25%, 45.83%, and 29.17% for beverage produced with SK grain, respectively.

Keywords: Kefir, yeasts, PCR-RFLP, *Kazachstania unispora*, *Saccharomyces cerevisiae*, *Kluyveromyces marxianus*

Abstract

Foot-and-mouth disease virus (FMDV) is a highly contagious viral infection affecting cloven-hoofed animals such as cattle, sheep, and pigs. The occurrence of outbreaks in the livestock industry has been demonstrated to result in significant economic losses and the implementation of international trade restrictions. Consequently, the early, accurate, and rapid detection of the disease is crucial to prevent its spread. The VP1 capsid protein, a structural component of the FMDV, plays a vital role in the virus's ability to adhere to host cells by interacting with integrin receptors located on the host cell surface. The 170-188 peptide sequence of the VP1 viral capsid protein plays a crucial role in the recognition of the virus by the immune system, as it functions as a virus-specific T-epitope. Consequently, the molecular detection of this peptide sequence indicates the presence of the antigenic structure of the virus, thus establishing the 170-188 peptide as a promising biomarker candidate for the diagnosis of FMDV. In this study, the detection of the 170-188 antigenic peptide was investigated using Surface-Enhanced Raman Spectroscopy (SERS), a highly sensitive and label-free analytical technique that enables the molecular identification of biomolecules through enhanced Raman scattering. The SERS-active substrate utilized for analyte detection was fabricated employing an innovative method that utilizes electrospinning to disperse silver ions onto the substrate surface, followed by thermal annealing, which enables in situ growth. The obtained spectral bands were then assigned to specific amino acid residues, thereby enabling the structural features of the peptide to be analyzed at the molecular level. The results demonstrate the promising potential of SERS in bioanalyte detection.

Integration of artificial intelligence in wastewater treatment for sustainable biogas generation

Şeyma Akkurt

Department of Environmental Engineering, Faculty of Engineering, Adıyaman University, Adıyaman, Turkey

Corresponding author e-mail: sakkurt@adiyaman.edu.tr

Abstract

The integration of Artificial Intelligence (AI) into wastewater treatment systems is becoming a critical pathway toward achieving sustainable energy and environmental goals. AI's ability to process large, complex, and nonlinear datasets enables unprecedented insight into the anaerobic digestion process, which is central to biogas generation. Traditional models often fail to capture the dynamic interactions among parameters such as temperature, pH, organic loading rate, and retention time. In contrast, AI techniques including Machine Learning (ML), Artificial Neural Networks (ANN), and Deep Learning (DL) allow accurate prediction, optimization, and control of biogas yield. This review highlights the growing importance of AI as a transformative tool that enhances process efficiency, operational stability, and methane recovery while reducing energy consumption and environmental impact. Current literature demonstrates that AI-driven models outperform conventional methods by adapting to real-time data and identifying complex system behaviors that are otherwise difficult to quantify. AI-based decision-support systems also offer intelligent automation, which makes it easier to manage treatment operations in a proactive way and helps with carbon-neutral energy recovery. Despite existing challenges related to data quality and model interpretability, AI stands as a cornerstone technology in transitioning wastewater treatment plants into smart, self-optimizing energy systems. Therefore, integrating AI is not only a technological advancement but also a strategic necessity for promoting sustainability, circular economy principles, and environmental resilience.

Abstract

The increasing prevalence of infectious diseases and antimicrobial resistance underscores the urgent need for novel therapeutic agents. Heterocyclic compounds are among the most significant structural motifs in medicinal chemistry due to their pharmacological versatility. Among them, pyrazoline derivatives have gained attention for their broad biological potential, including notable antimicrobial and antineoplastic properties [Karabacak, 2015]. In this study, chalcone intermediates were synthesized as key precursors, followed by the preparation of four methoxy-, hydroxy-, and chloro-substituted pyrazoline derivatives. The structures of all compounds were confirmed by NMR (^{1}H, ^{13}C, APT), MS, FT-IR, and UV analyses. The antimicrobial activity of the synthesized pyrazoline derivatives was evaluated by agar well diffusion and minimum inhibitory concentration (MIC) methods against *Staphylococcus aureus* (ATCC 29213), *Escherichia coli* (ATCC 25922), *Bacillus cereus* (ATCC 10876), and *Candida albicans* (ATCC 10231). All compounds showed significant inhibitory effects, particularly against *Candida albicans*, producing inhibition zones of 15–23 mm and inhibition rates between 50% and 115%. MIC and MBC/MFC results indicated compound-dependent antimicrobial activity. Compounds 6 and 7 exhibited the lowest MIC and MBC values, confirming strong bactericidal potential, especially against *B. cereus*. Moreover, compound 9 displayed the highest antifungal effect, with MIC and MFC values of 0.78 and 1.56 mg/mL against *C. albicans*. The synthesized pyrazoline derivatives demonstrated strong and broad-spectrum antimicrobial efficacy. These findings suggest that such heterocyclic frameworks may serve as valuable lead structures for the development of new antimicrobial agents.

Keywords: Heterocyclic compounds, Pyrazoline, Antimicrobial activity.

UV ve filtrasyon tabanlı balast suyu arıtım sistemlerinin saha performansı üzerine bir değerlendirme

Ülkü Demirci

İskenderun Teknik Üniversitesi, Bilim ve Teknoloji Uygulama ve Araştırma Merkezi, Hatay, Türkiye

Sorumlu yazar e-mail: ulku.demirci@iste.edu.tr

Özet

Balast suları, gemi stabilitesini sağlamak amacıyla kullanılsa da, farklı deniz ekosistemleri arasında canlı organizmaların taşınmasına neden olarak istilacı türlerin yayılımı açısından ciddi bir çevresel tehdit oluşturmaktadır. Bu riski azaltmak amacıyla Uluslararası Denizcilik Örgütü (IMO) tarafından 2004 yılında kabul edilen Balast Suyu Yönetimi Sözleşmesi (BWM 2004), 2017 itibarıyla yürürlüğe girerek gemilerde balast suyu arıtma sistemlerinin (BWTS) kullanılmasını zorunlu hale getirmiştir. Bu çalışmada, UV ve filtrasyon temelli bir balast suyu arıtma sisteminin saha performansı, IMO yönergelerine (BWM.2/Circ.70/Rev.1) uygun olarak gerçekleştirilen bir devreye alma testi (commissioning test) verileri üzerinden değerlendirilmiştir. Sistem 1000 m^3/saat nominal kapasitede çalışacak şekilde tasarlanmış olup, test sırasında ortalama debalast debisi 427 m^3/saat, toplam deşarj hacmi 350 m^3 ve tutma süresi 2 saat olarak kaydedilmiştir. Biyolojik etkinlik ölçümleri, Adenozin Trifosfat (ATP) yöntemiyle yapılmış ve hem ≥50 µm hem de 10–50 µm boyut sınıflarında IMO D-2 standardının altında (<10 organizma/m^3 ve <10 organizma/mL) sonuçlar elde edilmiştir. UV yoğunluğu 1869 W/m^2 olarak kaydedilmiş ve sistemin kendi kendini izleme (self-monitoring) donanımında herhangi bir alarm veya arıza tespit edilmemiştir. Elde edilen sonuçlar, UV + filtrasyon temelli sistemlerin saha koşullarında yüksek biyolojik etkinlik gösterdiğini ve D-2 standardı gerekliliklerini başarıyla karşıladığını ortaya koymuştur. Ancak tutma süresi ve debi değişkenlerinin performans üzerindeki olası etkilerinin, farklı gemi tiplerinde ileri saha çalışmalarıyla doğrulanması önerilmektedir.

Anahtar Kelimeler: Balast suyu yönetimi, UV arıtma, IMO D-2 standardı, deniz istilacı türleri, biyolojik etkinlik

Abstract

Biological invasion is one of the most significant problems of 21st century. The introduction of non-native species into new ecosystems is considered one of the main threats to biodiversity and ecosystem components. However, biological invasions cause not only ecological but also economic damage. Today, the Aegean Sea has become a region invaded by species entering through the Suez Canal and the Strait of Gibraltar. Increasing human-induced impacts (such as global warming and intensive maritime transport) have accelerated the invasion success of alien species entering the Mediterranean. In parallel, the number of non-native species distributed in the Mediterranean basin has exceeded 1,000. Although the detection, distribution, impact assessment, and monitoring of alien species in both terrestrial and aquatic ecosystems have been studied worldwide for many years, such studies have gained momentum in Türkiye only in the last decade. In this study, relevant literature was reviewed to determine the current status of alien fish species distributed along the Aegean coasts of Türkiye.

Assessing the impact of microbial dysbiosis on disease pathogenesis through a one health perspective

Ozge Ardicli

Bursa Uludag University, Bursa, Türkiye.

Corresponding author e-mail: ozgeyilmaz@uludag.edu.tr

Abstract

The microbiota comprises diverse microorganisms, including bacteria, fungi, and viruses, that colonize distinct body sites such as the gut, skin, and respiratory tract, forming a vital interface between the host and its environment. These microbial communities maintain epithelial barrier integrity, metabolic homeostasis, and immune tolerance. Dysbiosis, defined as an imbalance in microbial composition and function, disrupts these processes and contributes to the pathogenesis of various diseases. Multiple factors, including the use of chemicals in daily routines, dietary changes, antibiotic overuse, environmental pollutants, and reduced microbial exposure, can contribute to the development of dysbiosis. According to the epithelial barrier theory, the progressive loss of microbial diversity, together with environmental insults such as pollutants, detergents, and dietary additives, weakens epithelial integrity and increases permeability to allergens and pathogens. This breakdown of the physical and immunological barrier not only amplifies type 2-skewed inflammation but also links the global decline in microbial biodiversity to the growing prevalence of chronic allergic and inflammatory disorders. Distinct body sites in companion animals show specific microbial alterations linked to allergic and inflammatory diseases. In canine and feline atopic dermatitis, reduced microbial diversity and overgrowth of *Staphylococcus pseudintermedius* and *Malassezia pachydermatis* correlate with disease severity. Respiratory and gut microbiota of allergic pets also display increased *Proteobacteria* and *Clostridium* abundance, with reduced *Bacteroidetes*, impairing short-chain fatty acid production and epithelial immune tolerance.From a One Health perspective, comparable microbial perturbations and immune consequences are observed in animals and humans, underscoring the interconnectedness of host–microbiota relationships across species. Understanding dysbiosis-driven immune dysregulation provides critical insight for developing microbiota-targeted interventions that promote balanced immunity and barrier resilience in both human and veterinary medicine.

Keywords: microbial dysbiosis, microbiota, one health, companion animals

Abstract

Polyolefins such as polypropylene (PP) and linear low-density polyethylene (LLDPE) are extensively utilized in packaging, automotive, and outdoor applications owing to their cost-effectiveness, processability, and mechanical strength. Nonetheless, their vulnerability to photo-oxidative degradation under UV exposure results in chain scission, discoloration, and diminished mechanical properties. Hindered amine light stabilizers (HALS) counteract this degradation by neutralizing free radicals through a regenerative cyclic mechanism, thereby prolonging polymer service life. Conventional HALS, typically petrochemical-derived, can interact adversely with processing aids in LLDPE films, compromising efficiency.

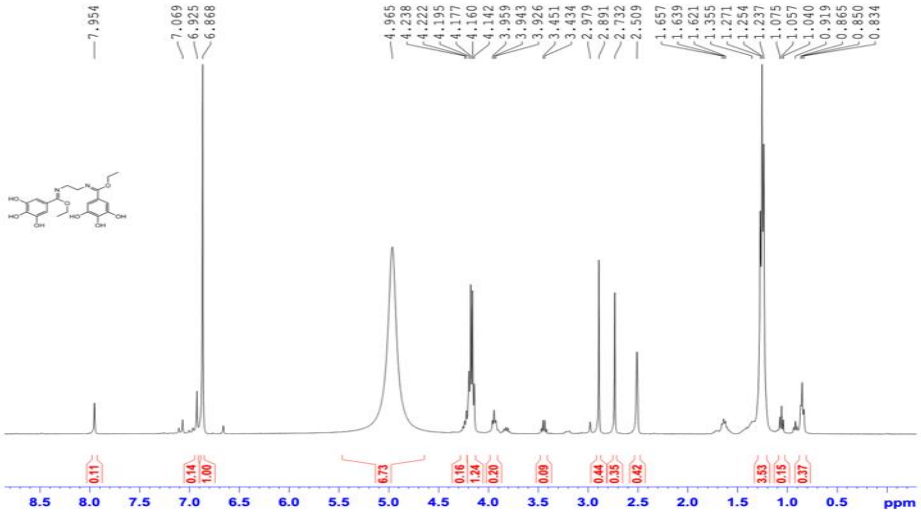

Figure: Dimetil N',N''-(etan-1,2-di)(1Z,1'E)-bis(3,4,5-trihidroksibenzimidat)'e ait NMR Spektrumu

This study reports the synthesis of four novel bio-derived HALS candidates: Schiff base derivatives from ethyl gallate/methyl gallate and diamines (ethylenediamine/1,6-hexanediamine) via condensation reactions in ethanol under reflux. These compounds exploit gallic acid's phenolic antioxidant framework for radical scavenging in polyolefins, augmented by imine linkages for enhanced thermal and UV resilience. The products were obtained in 75-88% yields as pale yellow solids. Structural confirmation was achieved through spectroscopic and thermal analyses. FTIR spectra displayed characteristic imine (C=N) stretches at 1648-1652 cm^{-1}, phenolic OH at 3400-3450 cm^{-1}, and ester C=O at 1715-1725 cm^{-1}. ^1H NMR (400 MHz, DMSO-d_6) revealed imine protons at δ 7.95-8.00 (s, 2H), aromatic protons at δ 6.87-7.07 (m, 4H), benzylic CH_2O- at δ 4.97 (s, 4H), and aliphatic signals including -OCH_2CH_3 at δ 4.20-4.24 (q, 4H, J = 7.1 Hz) and CH_3 at δ 1.04-1.27 (t, 6H, J = 7.1 Hz); for hexanediamine derivatives, additional - $(CH_2)_4$- methylene chains appeared at δ 1.23-1.64 (m, 8H). ^{13}C NMR (100 MHz, DMSO-d_6) confirmed ester carbonyls at δ 166.6-166.7 ppm, imine carbons at δ 162.8 ppm, aromatic quaternary C at δ 146.5 and 151.7 ppm, and olefinic/aromatic CH at δ 108.4-116.6 ppm; aliphatic carbons ranged from δ 14.4-60.7 ppm. UV-Vis spectra showed absorption maxima at 280-320 nm, indicative of π-π* transitions in the conjugated system. Thermal analyses via TGA exhibited decomposition onsets >260°C (5% weight loss) under N_2, with DSC revealing glass transitions at 95-110°C and melting points of 185-210°C, suggesting suitability for polymer processing. These gallate-based Schiff bases represent sustainable HALS precursors with inherent antioxidant-photostabilizing motifs, paving the way for eco-friendly polyolefin enhancements.

Keywords: Schiff bases, HALS, gallic acid esters, NMR characterization, polymer stabilization.

Abstract

Autism spectrum disorder (ASD) is a complex neurological and developmental disorder characterized by persistent deficits in social communication, repetitive behaviors and, restricted interests with a strong genetic component underlying its etiology. Among the numerous candidate genes associated with ASD, *CDH9* (Cadherin-9) encodes a calcium-dependent cell adhesion protein that plays a critical role in synaptic organization, neuronal connectivity, and the establishment of specific neural circuits during brain development. In the present study, SNAP, SIFT, PolyPhen-2 (HumDiv and HumVar), SNPs&GO, PhD-SNP, PANTHER, and Meta-SNP computational tools were employed to evaluate potentially deleterious missense variants within the *CDH9* gene. The impact of these variants on protein stability was assessed using I-Mutant 2.0 and MUpro, while GeneMANIA and STRING were utilized to explore gene–gene and protein–protein interaction networks, respectively. Additionally, Missense3D was used to visualize three-dimensional conformational changes. As a result of these analyses, six missense SNPs were predicted to have a shared deleterious effect and were potentially associated with ASD pathogenesis: rs143800304 (D483N), rs148731332 (R448W), rs149817725 (E741G), rs199818706 (G310E), rs200287957 (G610V), and rs371558373 (G742R). Overall, these findings highlight the pathogenic potential of missense SNPs in the *CDH9* gene and propose these variants as strong candidates for future experimental validation in understanding the molecular mechanisms underlying autism spectrum disorder.

Keywords: *CDH9* gene, *in silico*, polymorphism, autism spectrum disorders

Abstract

Biodegradable metal biomaterials have the advantage of self-decomposition in the body and prevents further surgery to take them back after healing process. This makes them good alternatives for bone fixation applications. Among biodegradable metal alloys Mg alloys have been investigated widely due to their superior advantages e.g. biocompatibility, low density, comparable mechanical properties with living tissue (bone). Besides these advantages the considerably fast degradation kinetics of Mg alloys in the body (body fluid environment) is an important drawback. The metallic alloy should stay intact (i.e. keep its mechanical strength) during healing of the wounded tissue. There are different approaches on elongation of the degradation time of the Mg alloys like doping the alloy with different metals to prepare a more durable metallic alloy or modifying the surface of the alloy for enhanced durability against chemical degradation. Application of coatings with biocompatible materials on Mg alloys is a convenient method to control the biodegradation stability of Mg alloy at certain levels. Besides, these coatings may act as active agents for enhancing the healing process. Hydroxyapatite (HA) is a bioactive ceramic material which has chemical structure resemblance with the bone. Coating of Mg alloys with HA may balance the degradation rate of the alloy in the body, and it may also help the healing process of the bone tissue. In the current study Mg alloy samples were coated with nano HA and the effect of the coating on the biodegradation of the alloy was investigated. The coating process parameters (coating technique, recipe, etc.) were changed to determine their effects on the structure/performance of the coating. The biodegradation of the alloy in simulated body fluid (*in vitro*) was elongated considerably with the applied coating layer compared to the uncoated alloy.

Keywords: Mg alloy, biomaterial, nano hydroxyapatite, coating, biodegradation.

Abstract

Alzheimer's disease (AD) is the most common cause of dementia in adults and one of the most prevalent neurodegenerative diseases worldwide. AD accounts for approximately 60–80% of all dementia cases. (Alzheimer's Association, 2024; WHO, 2023). The pathogenesis of the disease is multifactorial and has not yet been fully elucidated. Today, pharmacological treatment approaches for Alzheimer's disease are largely based on the cholinergic hypothesis. The main goal of this approach is to enhance neurotransmission and improve cognitive function by increasing ACh levels in the synaptic cleft. The most commonly used drugs for this purpose belong to the group of acetylcholinesterase inhibitors, which inhibit the enzyme responsible for the hydrolysis of ACh. The main agents in this group are donepezil, rivastigmine, and galantamine (Marucci et al., 2021). These drugs only provide temporary cognitive improvement; they cannot halt the progression of the disease and may cause side effects such as nausea, muscle weakness, or liver toxicity(Hampel et al., 2021; Venugopal et al., 2024). Therefore, there is a need to develop safer and more effective compounds. In recent years, hydrazones and their derivatives have attracted attention due to their structural flexibility, the inclusion of biologically active pharmacophore groups, and their high biological activity (Rollas & Güniz Küçükgüzel, 2007).The effects of hydrazones on AChE/BuChE inhibition are known (Bartolić et al., 2024; Sıcak et al., 2019), but there is currently no hydrazone derivative compound used in the treatment of Alzheimer's disease. In this study, 11 new *N*-(2-{2-[2-substitutedbenzylidenehydrazin-1-yl]-2-oxoethoxy}phenyl)acetamide derivatives containing a hydrazide-hydrazone structure were synthesized from orthocetamol with %66-97 yield. The purities of the synthesized compounds were determined by melting point determination and HPLC, and their structures were elucidated using spectroscopic methods. The *in silico* binding affinities of the synthesized compounds against AChE and BuChE enzymes were evaluated, and ligand-binding site interactions were presented.

Keywords: AChE, BuChE, hydrazone, synthesis, docking

Özet

Kolon kanseri, dünya genelinde en yaygın görülen ve yüksek mortalite oranına sahip üçüncü kanser türüdür. Günümüzde mevcut tedavi yöntemlerine ek olarak, doğal kaynaklı bileşikler ve bitki ekstraktlarının terapötik potansiyelleri üzerine yapılan çalışmalar giderek artmaktadır. Bu çalışmada, Akdeniz bölgesinde yaygın olarak bulunan *Cistus laurifolius* L. (karağan) bitki ekstraktının kolon kanseri hücre hattı (HCT116) üzerindeki etkileri incelenmiştir. *C. laurifolius* bitkisi doğadan toplanarak ekstraktı hazırlanmış ve farklı konsantrasyonlarda (25, 50, 100, 200, 400, 800 µg/mL) HCT116 kolon kanseri hücre hattına ve sağlıklı insan endotel hücrelerine (HUVEC) 48 saat süreyle uygulanmıştır. Uygulama sonunda elde edilen absorbans değerleri, kontrol gruplarına göre normalize edilerek her iki hücre hattında canlılık oranları hesaplanmıştır. Sağlıklı hücrelerde düşük konsantrasyonlarda (25 µg/mL ve 50 µg/mL) hücre canlılığında sırasıyla %6 ve %12 oranında artış gözlenirken, 100 µg/mL'de %16, 200 µg/mL'de %48 ve 400–800 µg/mL'de yaklaşık %95 oranında hücre ölümü meydana gelmiştir. HCT116 hücrelerinde ise 200 µg/mL, 400 µg/mL ve 800 µg/mL konsantrasyonlarında yaklaşık %95 oranında hücre ölümünün gerçekleştiği, düşük konsantrasyonlarda (25–100 µg/mL) ise %10 civarında hücre ölümünün gözlendiği belirlenmiştir. Elde edilen bulgular, *C. laurifolius* ekstraktının 48 saatlik uygulama sonunda HCT116 kolon kanseri hücrelerinde belirgin bir anti-kanser etki gösterdiğini ortaya koymaktadır. Etkinin doza bağlı olarak arttığı saptanmıştır. Bu sonuçlar, yeterli deneysel ve moleküler düzeyde çalışmalarla desteklendiğinde, *C. laurifolius*'un kolon kanseri tedavisinde umut vaat eden doğal bir ajan olabileceğini göstermektedir.

Abstract

How efficiently, environmentally friendly, and sustainably a country uses its energy resources is a direct determinant of its economic growth, industrialization, prosperity, and environmental balance. Environmental issues such as the threat of depletion of traditional energy sources over time and global warming and climate change caused by greenhouse gases released from their combustion have increased interest in renewable energy sources. In this context, hydrogen stands out as a clean and environmentally friendly energy source that can replace fossil fuels. Although hydrogen is abundant in nature, it is not found in free form. It is generally found in the structures of substances such as water, hydrocarbons, and organic compounds. Therefore, it can be obtained through various production techniques such as gas reforming, water electrolysis, biochemical processes, and thermochemical methods. Due to their high hydrogen content, high energy density, hydrogen release ability, and relative abundance in nature, chemical hydrides ($LiBH_4$, KBH_4, $NaBH_4$, etc.) are important materials for hydrogen storage and production. Sodium borohydride from these hydrides; It is a non-toxic, non-flammable, chemically stable, and safe compound with a hydrogen content of approximately 10.8%. Due to these advantageous properties, $NaBH_4$ is an effective hydride source preferred in many studies on hydrogen production. In this study, hydrogen production by methanolysis of sodium borohydride was investigated. Silica gel-supported monometallic catalysts were developed to accelerate the methanolysis reaction. Co, Nb, and Cu metals were loaded onto the silica gel support by wet impregnation method and their catalytic activities in the methanolysis reaction were compared. Hydrogen production rates of Co/SiO_2, Nb/SiO_2 and Cu/SiO_2 catalysts were obtained as 3291.24, 3335.4 and 8781.0 $mL/g_{cat}.min$ respectively. Kinetic studies were carried out on the Cu/SiO_2 catalyst, which has a higher hydrogen production rate compared to other monometallic catalysts. At the end of the kinetic studies, the Cu/SiO_2 catalyst was promising for the methanolysis reaction with its high hydrogen production rate obtained.

Keywords: Hydrogen, sodium borohydride, methanolysis, silica gel.

Abstract

Human epidermal growth factor receptor 2 (HER2) and the macrophage migration inhibitory factor (MIF) amplification are frequently implicated in tumor aggressiveness, immune evasion, and treatment resistance. Recent findings suggest that MIF and HER2 may cooperate through the HSF1-HSP90 signalling axis. Here, we aimed to develop a bioinformatic model to analyse MIF-HER2 co-expression patterns and their interactions with the tumor microenvironment using multiple datasets. Differential expression and correlation studies were performed using METABRIC, TCGA and GEO cohorts. Moreover, protein-protein interaction (PPI) networks were constructed using STRING (confidence 0.7 and above) and visualized in Cytoscape (v3.10.3). Network topology and centrality analyses were used to identify hub genes, which were then cross-referenced with expression fold changes between tumor and normal tissues. We found that, MIF and HER2 were markedly overexpressed in breast and colorectal tumors as compared to the normal tissues. In breast cancer, HER2-high tumors showed significantly elevated MIF levels ($p < 0.001$), which was consistently observed across TCGA and METABRIC datasets. In colorectal cancer, MIF expression was upregulated in HER2-positive tumors, although HER2 itself did not exhibit substantial expression differences within the same cohort. Furthermore, network analysis revealed *MIF, TOP2A* and *CTSD* as major hub genes in breast cancer, while *MIF*, *CD44* and *CDC25C* emerged as central hubs in colorectal cancer. These genes were predominantly associated with pathways related to proliferation, inflammation and metabolic adaptation. Overall, these findings suggest that MIF acts as a key modulator within HER2-regulated signalling networks and represents a potential co-target for therapy. The conserved MIF-HER2 expression axis may promote tumor progression through shared oncogenic and inflammatory pathways. Future experimental studies investigating dual MIF and HER2 inhibition *in vitro* are warranted to validate these bioinformatic analyses.

Abstract

Biocomposites are described as composite materials that contain at least one component, either the matrix or the reinforcement, derived from a biological source [1]. The fabrication of biocomposites generally relies on traditional polymer processing methods, including extrusion and solvent casting [2]. Biocomposites are increasingly utilized in various industries such as construction, automotive, and packaging because of their low density, renewable origin, and environmentally friendly degradability [3]. Orange peel, which contains a high amount of natural polymers such as cellulose, lignin, and pectin, has emerged as a valuable bio-based raw material for bioplastic production. According to recent studies, films derived from orange peel exhibit the lowest solubility in water and ethanol, demonstrating excellent structural stability. Moreover, due to its low solubility and antimicrobial properties, orange peel is considered an eco-friendly additive that enhances the durability and environmental sustainability of biocomposites [4]. Within the scope of this study, biodegradable Poly(lactic acid) (PLA) matrices will be reinforced with orange peel powder (OPP) as a natural filler to produce biocomposite films. The orange peels will be washed, dried, and ground to an appropriate particle size, while PLA will be dissolved in chloroform and mixed with OPP at specific ratios. The obtained mixture will be cast onto glass plates and dried at room temperature to form biocomposite films. The prepared samples will be characterized by FTIR analysis, mechanical testing, water contact angle measurements, swelling ratio, and biodegradability (soil burial) tests.

Keywords: Biocomposites, Poly(lactic acid) (PLA), Orange peel powder (OPP), Biodegradable materials

Abstract

Gliomas account for approximately 30% of all primary intracranial neoplasms and 80% of malignant cases, making them the most common primary malignant brain tumors. Netrin-4, a member of Netrin, is an important secreted protein involved in axonal growth and differentiation, and is involved in the regulation of various physiological processes and the formation and metastasis of various tumors, including gliomas. There are controversial results regarding the expression of netrin-4 and its receptors, neogenin and UNC5B in glioma. The study aims to investigate whether there is a change in serum levels of Netrin-4, neogenin and UNC5B in patients compared to controls. In this study, serum Netrin-4, neogenin, and UNC5B levels were measured by ELISA method using commercial kits in 44 glioma patients and 45 healthy controls. Serum Netrin-4 and neogenin levels were found to be significantly lower in glioma patients compared to control groups $p<0.05$, $p<0.05$, respectively), whereas UNC5B levels were not different ($p>0.05$). Some studies show that Netrin-4, neogenin and UNC5B expressions are altered in glioma cell lines. Our findings in serum samples are consistent with cell culture studies reporting low expressions of Netrin-4 and neogenin in glioma.

Keywords: Netrin-4, Neogenin, UNC5B, Glioma

Abstract

Inflammation is a self-protective biological response of the body against pathogens, cellular damage or toxic compounds, characterized by the activation of various biochemical processes and immune cells. These factors may trigger acute or chronic inflammatory responses in tissues, leading to tissue damage and thereby the development of various pathological conditions. Therefore, understanding the molecular signals associated with inflammatory responses is crucial for the development of novel therapeutic approaches to pathologies at the cellular or tissue level that may be caused by inflammation. Today, it has been demonstrated that many drugs used for various clinical purposes can be utilized to modulate inflammatory responses. Recent *in vitro* and *in vivo* studies suggested that agomelatine may play a protective role in LPS-induced inflammation, which is an agonist of the melatonin receptor and a selective inhibitor of the serotonin 2C receptor. However, its comprehensive mechanism has not been elucidated yet. Thus, we aimed to investigate the protective role of agomelatine on LPS-induced inflammation caused cellular damage in the present study by evaluating the ER stress and apoptotic responses. For this aim, the protective effect of agomelatine on LPS-induced inflammatory and apoptotic responses in HEK293 human embryonic kidney cells was studied by several methodologies. To investigate the protective role of agomelatine, the mRNA expression levels of ER stress-associated *BiP/GRP78* and *CHOP*, pro-apoptotic *BAX*, *BiD* and anti-apoptotic *BCL2*, *BCL-xL* were tested by qRT-PCR. Furthermore, the LPS-induced inflammatory response was verified by testing *TNF-α* and *IL-6* expression. Additionally, protein levels of caspase-3 and CHOP were examined by immunoblotting. Our data revealed that agomelatine treatment significantly reduced the LPS-induced inflammation caused ER stress and apoptotic signaling in HEK293 cells. Present findings suggest that agomelatine may contribute to the maintenance of cellular homeostasis by reducing inflammation-induced ER stress and apoptotic response.

Abstract

Pancreatic ductal adenocarcinoma (PDAC) is among the solid tumors with the highest mortality rates due to its aggressive nature and late diagnosis. Early-stage PDAC often presents without obvious symptoms, and the deep anatomical location of the pancreas leads to the disease being diagnosed mostly at an advanced stage, resulting in poor survival rates. Its dense desmoplastic stroma limits drug penetration, contributing to chemoresistance, while resistance mechanisms that emerge over time reduce treatment efficacy and lead to disease recurrence. Therefore, developing new therapeutic strategies for PDAC is of critical importance. The anticancer potential of green-synthesized silver nanoparticles (AgNPs) has been reported in various studies. Synthesizing silver nanoparticles in a composite structure with graphene oxide (GO) enhances nanoparticle stability and allows these structures to be evaluated as potential therapeutic or drug delivery candidates. Plant-mediated synthesis offers advantages such as low toxicity, high stabilization, and environmentally friendly production. In this study, the effects of GO-AgNP composites synthesized using Laurus nobilis extract in combination with the standard chemotherapeutic agent gemcitabine were investigated for PDAC treatment. AgNP, GO, and GO-AgNP structures were characterized using UV-Vis spectroscopy, TEM, FESEM, and XRD methods, and their cytotoxicity was evaluated on the Panc-1 cell line using the MTT assay. RT-PCR results showed that the combination of GO-AgNP and gemcitabine enhanced apoptosis in Panc-1 cells by decreasing Bcl-2 levels and increasing Bax levels. Additionally, suppression of VEGFA, FLT-1, and VEGFR-2 expression indicated inhibition of angiogenesis. A decrease in MMP2 levels and an increase in TIMP2 levels suggested a slowdown of the EMT process, which was confirmed at the protein level by measuring MMP2 levels using Western blot analysis. The findings foresee a potential synergistic effect of the combination of GO-AgNP and gemcitabine in PDAC treatment.

Abstract

The association between plant-based diets and breast cancer (BC) prevention has gained growing attention in recent public health research. Accumulating evidence from cohort and intervention studies suggests that adherence to whole-food, plant-based (WFPB) and healthful plant-based dietary patterns (hPDI)—characterized by high intake of fruits, vegetables, legumes, whole grains, and nuts, and low consumption of animal and processed foods—can significantly reduce BC incidence, recurrence, and mortality. These dietary models contribute to improved metabolic profiles, including reduced body weight, fasting insulin, and low-density lipoprotein (LDL) cholesterol levels, together with enhanced hormonal balance through elevated sex hormone-binding globulin (SHBG) concentrations. Such outcomes highlight the potential of plant-centered diets in supporting both disease prevention and long-term survival among breast cancer patients. Mechanistically, plant-based diets exert protective effects by improving insulin sensitivity, reducing chronic inflammation, and lowering circulating insulin-like growth factor-1 (IGF-1). They also promote estrogen metabolism and maintain a balanced gut microbiota, which collectively modulate key pathways involved in carcinogenesis. Moreover, the abundance of phytochemicals such as flavonoids, carotenoids, and phenolic compounds provides potent antioxidant and anti-inflammatory actions that help inhibit oxidative stress, angiogenesis, and tumor-promoting signaling mechanisms. Overall, current evidence indicates that WFPB and hPDI dietary patterns support both primary prevention and better survivorship in breast cancer by modulating oxidative stress, inflammation, and hormonal homeostasis. Although additional studies are needed to clarify the roles of specific bioactive components, plant-based diets presently represent an effective and sustainable approach to reducing breast cancer risk and improving patient outcomes.

Abstract

Copper oxide nanoparticles (CuO NPs) are regarded as effective adsorbent materials due to their low cost, large surface area, abundant active sites, and strong affinity for contaminants. This study utilized green synthesis by preparing CuO NPs through a precipitation approach in a deep eutectic solvent (DES) composed of choline chloride, ethylene glycol, and water. The main objective was to assess these nanoparticles for removal of metronidazole (MTZ), a pharmaceutical pollutant, from water. The synthesized CuO NPs were characterized using BET, SEM, FTIR, and XRD techniques, revealing their optimal morphology, well-defined crystalline structure, and monoclinic phase. The average crystallite size, estimated with the Debye–Scherrer equation, was 70.42 nm. HPLC analyses demonstrated that the CuO NPs effectively adsorbed MTZ, with a maximum monolayer adsorption capacity of 29.39 mg/g. Adsorption followed the Langmuir isotherm and pseudo-second-order kinetic model, indicating that the process is dominated by monolayer coverage on homogenous surfaces. Thermodynamic studies confirmed that adsorption was spontaneous and endothermic, which underscores the benefits of DES-assisted synthesis on adsorption efficiency. This study highlights that using a ternary DES (ChCl:EG:H_2O) serves both as a green reaction medium and as a surface modifier, enabling the production of CuO NPs with enhanced nanostructural features and superior adsorption performance towards MTZ. The successful application of a sustainable, DES-based synthetic route illustrates a promising, environmentally friendly strategy for addressing pharmaceutical pollution during water treatment. These findings support the further investigation and development of DES-mediated nanomaterials for advanced environmental applications.

Abstract

Human immunodeficiency virus (HIV) remains a formidable global health threat, in large part because latent reservoirs persist despite potent combination therapies. A critical event in the viral life cycle is the recruitment of the Gag polyprotein precursor ($Pr55^{gag}$) to the plasma membrane, where it assembles into immature lattices before protease-driven cleavage yields the structural proteins matrix (MA), capsid (CA), nucleocapsid (NC) and p6. Membrane engagement is orchestrated by the MA domain through its selective interaction with phosphatidylinositol-4,5-bisphosphate ($PI(4,5)P_2$), making MA a strategic node for therapeutic disruption. We previously introduced an inositol-hexakisphosphate-derived molecule, L-HIPPO, designed to interfere with this MA-lipid interface. We found that L-HIPPO effectively immobilizes HIV within infected cells, triggering apoptosis of the host cell together with the trapped virions. This mechanism provides a conceptual framework for therapies aimed at forcing viral self-elimination and achieving complete clearance of infection. We set out to design and synthesize next-generation L-HIPPO derivatives with enhanced mechanistic antiviral activity. Building on our earlier observations that the two acyl chains of L-HIPPO constitute the most structurally tunable elements, positioned directly within the membrane interface, we rationally designed eight new derivatives by modifying these regions. We then performed structure-based docking using Schrödinger software and three high-resolution MA-IP_6 complex structures (PDB: 7E1I, 7E1J, 7E1K) previously resolved by our group, enabling a precise assessment of how each analogue engages the MA binding pocket. In this work, we first synthesized the required starting material and intermediate compounds through a six-step sequence to obtain compound a (30% overall yield, 200 mg), and we confirmed their structures by ^{1}H NMR, ^{13}C NMR, and HRMS analyses. The synthesis of the final L-HIPPO derivatives from compound a is now in progress. In subsequent stages, we will assess their ability to induce apoptosis in HIV-1-infected HeLa cells, providing insight into their potential to disrupt viral persistence.

Abstract

Fluorescence sensors are of great importance in many areas, including environmental, food safety, medicine, and industry, because they offer low-cost, rapid, highly sensitive, and selective detection methods for chemical and biological analyses. Key factors determining the effectiveness of these sensors include the specific binding ability of the target analyte and the strength of the fluorescence response. In this context, the design and synthesis of fluorescent molecules plays a critical role. In this study, a cyanobiphenyl-based fluorescent sensor containing a quinolinium moiety was successfully synthesized through the Knoevenagel condensation reaction and its structure was confirmed by Nuclear Magnetic Resonance (NMR) spectroscopy. The Knoevenagel reaction is a base-catalyzed process that forms α,β-unsaturated carbonyl compounds via the condensation of carbonyl compounds with active methylene groups. This reaction pathway enables the formation of extended π-conjugated systems, which play a crucial role in enhancing fluorescence efficiency. The incorporation of the quinolinium unit and the conjugated cyanobiphenyl structure provides strong electron delocalization, resulting in improved optical properties. Due to these characteristics, the synthesized compound exhibits potential as a versatile fluorescent material for the development of chemical sensors sensitive to environmental changes or metal ions.

Keywords: Fluorescent sensor, Cyanobiphenyl, Quinolinium

Abstract

Overactive bladder (OAB) is a highly prevalent syndrome characterised by symptoms of urgency in the absence of urinary tract infection or other discernible pathology. OAB has complex etiologies and it is usually associated with detrusor overactivity (DO), defined as involuntary detrusor muscle contractions. Nitric oxide (NO) is an important neurotransmitter in the lower urinary tract, mediating the relaxation of detrusor. Chronic inhibition of NO synthesis by Nω-nitro-L-arginine methyl ester hydrochloride (L-NAME) has been demonstrated to induce DO in rodents. Trimetazidine (TMZ) is a widely used anti-anginal agent, primarily acting through the modulation of cardiac energy metabolism. Recently, TMZ has also been reported to exhibit an inhibitory effect on detrusor contractility *in vitro*, demonstrating therapeutic potential in bladder dysfunction. However, the effect of TMZ in OAB has not been clarified yet. This study aimed to evaluate the effect of TMZ on detrusor contractility in a mouse model of L-NAME-induced OAB. Male Balb/c mice were administered L-NAME (60 mg/kg) daily via oral gavage for 30 consecutive days. Thirty minutes following L-NAME administration, TMZ (20 or 80 mg/kg) was administered intraperitoneally once daily for the same 30-day period. 24 hours after the last treatment, detrusor strips were prepared and contractility studies were performed using isolated organ baths to evaluate the contractile responses. Chronic L-NAME treatment markedly enhanced KCl-, carbachol- and $CaCl_2$-induced contractions of detrusor strips compared to control, implying that long-term NO deficiency leads to OAB. However, TMZ failed to attenuate DO in L-NAME-treated mice. The findings of our study indicate that TMZ was ineffective in reversing DO in a mouse model of OAB induced by L-NAME. Further studies are required to test the therapeutic potential of TMZ using different functional methods within alternative *in vivo* OAB models. This study was funded by TÜBİTAK under the 2209-A University Students Research Projects Support Programme.

Abstract

Depression and anxiety are widespread psychiatric concenrns affecting a substantial portion of the global population. Antidepressant medications, such as desipramine, an active tricyclic antidepressant compound, are commonly prescribed for long-term use; however, their potential genotoxic (DNA and chromosome damaging) and cytotoxic (cell damaging) effects remain underexplored. This study aimed to evaluate the genotoxicity and cytotoxicity of desipramine using *Allium cepa* (*A. cepa*) root tip cells through the Allium test and Comet assay. Desipramine was applied at six concentrations (1.5, 3, 6, 12, 18, and 24 µg/mL) for 24 and 48 hours. Results demonstrated a dose- and time-dependent reduction in the mitotic index, indicating cytotoxic effects. Additionally, a significant increase in the frequency of mitotic abnormalities was observed in the 48-hour treatment group at all concentrations, whereas the 24-hour exposure induced significant abnormalities only at concentrations ≥12 µg/mL. The Comet assay further revealed a marked increase in DNA damage in desipramine-treated groups at all concentrations and time points, relative to the negative control. These findings indicate that desipramine induces both cytotoxic and genotoxic effects in *A. cepa* root tip cells, highlighting its potential risk to living organisms upon prolonged or high-dose exposure. Given the widespread and often chronic use of antidepressants, it is crucial to further investigate their long-term biological impacts. A thorough reassessment of the risk-benefit profile of desipramine and similar compounds is warranted, considering their implications for both human and environmental health.

Abstract

Acute myeloid leukemia (AML) is a malignancy characterized by the abnormal proliferation and accumulation of myeloid progenitor cells in the bone marrow and peripheral blood. Identifying cellular responses to inflammation in AML is critical for developing new diagnostic and therapeutic strategies in this area. This study aims to evaluate apoptosis, pyroptosis, and lymphocyte differentiation processes in a TNF-α-mediated chronic inflammation model of AML, the most common type of leukemia among hematologic malignancies. The study further aims to demonstrate how inflammatory environments regulate immune responses in cancer cells and activate cell death mechanisms. HL-60 cells were treated with TNF-α for 15 days to induce chronic inflammation. Subsequently, programmed cell death mechanisms associated with inflammation, namely pyroptosis and apoptosis, as well as lymphocytic differentiation potential, were examined in AML cells under chronic inflammation. TNF-α-treated cells showed increased expression of PD-L1, HMGB1, GSDME, CD68, and CD11a/18 compared to controls, along with enhanced apoptosis, suggesting an induction of programmed cell death. These findings indicate that prolonged exposure to cytokines such as TNF-α creates a complex effect within the cancer microenvironment, both activating immune responses and promoting immune evasion mechanisms in cancer cells. Such insights may guide the development of therapeutic strategies for cancers associated with inflammation, such as leukemia.

Abstract

Royal jelly (*Apis mellifera* L.) is a natural secretion produced by the hypopharyngeal and mandibular glands of worker honeybees to nourish larvae and the queen. It is a yellowish-white, viscous substance with an acidic and pungent taste. Owing to its complex chemical composition, royal jelly possesses high biological value and is rich in proteins, peptides, carbohydrates, fatty acids, vitamins, and other bioactive compounds. Its diverse biological activities include antibacterial, antiviral, antioxidant, antitumor, and skin-lightening effects. The primary contributors to these activities are the major royal jelly proteins (MRJPs) and 10-hydroxy-2-decenoic acid (10-HDA), the latter being a fatty acid unique to royal jelly and recognized as both a quality indicator and a marker of biological activity. In this study, the 10-HDA content of royal jelly and its inhibitory effect on the tyrosinase enzyme were evaluated. High-Performance Liquid Chromatography (HPLC) analysis revealed that 10-HDA content of royal jelly was 5.85% and 2.02% on a dry and fresh matter basis, respectively. The tyrosinase inhibitory activity was assessed spectrophotometrically using fungal tyrosinase (*Agaricus bisporus*) as the enzyme, L-DOPA as the substrate, and kojic acid as the positive control. The results demonstrated that enzyme activity decreased in a dose-dependent manner with increasing concentrations of royal jelly. The IC_{50} values were calculated as 14.2 mg/mL for royal jelly and 59.7 µM for kojic acid. Kinetic analyses indicated that both inhibitors could bind to the free enzyme and the enzyme-substrate complex, thereby exhibiting a mixed-type inhibition mechanism. These results indicate that the bioactive components of royal jelly, particularly 10-HDA, suppress tyrosinase activity by interfering both substrate binding and product formation within the enzyme's catalytic cycle. In conclusion, royal jelly with high 10-HDA content can be considered as a promising natural tyrosinase inhibitor with potential applications in dermocosmetic and pharmaceutical formulations.

Keywords: royal jelly, 10-HDA, tyrosinase, enzyme inhibition

Abstract

The discharge of synthetic dyes from textile industries into aquatic systems poses a major environmental challenge due to their toxicity, stability, and resistance to biological degradation. In this study, biochar produced from olive stone biomass was investigated as a low-cost and sustainable adsorbent for the removal of anionic textile dyes from aqueous solutions. Orange II, Procion Red, and Reactive Black were selected as model dyes, and batch adsorption experiments were conducted at initial dye concentrations of 20, 35, and 50 mg L^{-1} under different contact times. Percent removal efficiencies were calculated to evaluate the adsorption performance. The obtained results demonstrated that olive-stone-derived biochar exhibited notable removal efficiency for all three anionic dyes, indicating strong affinity and potential surface interactions between the biochar functional groups and dye molecules. Moreover, both contact time and initial concentration were found to influence adsorption behavior. Overall, this study highlights the feasibility of valorizing olive processing residues into a promising biochar adsorbent for water treatment, contributing to sustainable resource utilization and circular economy-based remediation strategies.

Keywords: Biochar, Anionic dyes, Adsorption, Water treatment, Resource valorization.

Abstract

In classical white cheese production, the process is completed during the ripening stage, which plays a decisive role in the development of the cheese's taste, aroma, texture, and overall quality characteristics. In the industry, ripening is traditionally carried out in lacquered tin containers with brine over a period of 3–9 months. This study aimed to evaluate the use of vacuum PA/PE packaging as an alternative to tin containers during the ripening of classical white cheese and to determine the effects of vacuum packaging on quality parameters. Cheese production was conducted at the Akpınar A.Ş. dairy processing facility following the standard white cheese production process. The produced cheese was divided into two groups: the first group was hermetically packaged in tin containers, while the second group was packaged in vacuum PA/PE (polyamide/polyethylene) bags. Both groups were stored at 4±2 °C and ripened for a total of 270 days. To assess quality changes, samples were taken monthly and subjected to sensory, chemical, and microbiological analyses. The results indicated that the type of packaging notably influenced sensory quality. During the first three months, both groups exhibited similar characteristics; however, from the fourth month onwards, tin-packaged cheeses showed superior pore structure and mature taste. By the eighth and ninth months of ripening, more pronounced differences were observed: tin-packaged cheeses maintained intense flavor and aroma along with a porous, firm texture, whereas vacuum PA/PE-packaged cheeses displayed a more elastic, non-porous texture with a unidirectional taste and aroma profile. Microbiological quality and migration analyses revealed no adverse findings in either packaging group, confirming that the cheeses remained safe for consumption. In conclusion, the type of packaging used during the cheese ripening process was found to directly affect sensory characteristics, particularly the development of taste and aroma.

Özet

Melanom, melanin sentezinden sorumlu melanositlerin malign transformasyonu sonucunda gelişen agresif bir cilt kanseridir. Geç tanı ve hızla ilerleme eğilimi nedeniyle ileri evre melanomun tedavisinde daha az toksik ve daha etkili ajanlar geliştirme ihtiyacı giderek artmaktadır. Son yıllarda elementel bor, yeni terapötik moleküllerin tasarlanmasında dikkat çekici özellikleri nedeniyle ilgi odağı hâline gelmiştir. Borik asidin (BA) çeşitli kanser türlerinde sitotoksik etki gösterdiği bildirilmiş olsa da altında yatan moleküler mekanizmalar tam olarak aydınlatılamamıştır. Bu çalışmada, BA'nın Malme-3M melanom hücrelerinde proliferasyon, apoptoz ve oksidatif stres üzerindeki etkileri değerlendirilmiştir. BA'nın hücre canlılığı üzerindeki etkisi 24, 48 ve 72 saatlik uygulamalar sonrasında MTT yöntemi ile analiz edilmiştir ve BA'nın 48. saatteki IC_{50} değeri 58.95 mM olarak belirlenmiştir. Apoptoza yönelik değişiklikler Annexin ELISA testi ve ilgili gen ekspresyon analizleriyle incelenmiştir. Apoptozla ilişkili Bcl-2, Bax, Kaspaz-3, -8, -9 ve Annexin V ekspresyon düzeyleri RT-qPCR ve ELISA yöntemleri kullanılarak değerlendirilmiştir. BA uygulaması sonucunda antiapoptotik genlerin baskılandığı, proapoptotik genlerin ise arttığı gözlenmiş; Annexin V düzeylerindeki yükselme apoptozun indüklendiğini desteklemiştir. Oksidatif stres değerlendirmesinde toplam oksidan seviye (TOS), toplam antioksidan kapasite (TAS) ve oksidatif stres indeksi (OSI) hesaplanmıştır. Uygulanan farklı BA konsantrasyonları sonrasında, hücrelerde TOS'un yükseldiği ve TAS'ın azaldığı gösterilmiştir. Artan TOS, azalan TAS seviyeleri ile hesaplanan OSI değeri ise IC 50 dozunda en yüksek seviyede tespit edilmiştir. Elde edilen bulgular, BA'nın Malme-3M hücrelerinde apoptozu indüklediğini açıkça ortaya koymaktadır. Genel olarak, BA'nın Melanom hücre hattında hücre çoğalmasını inhibe eden, apoptozu tetikleyen ve antioksidan kapasiteyi azaltan etkileri, bu bileşiğin melanom tedavisinde potansiyel bir antikanser ajan adayı olarak değerlendirilmektedir.

Anahtar Kelimeler: Borik asit, Melanom, Antikanser, Apoptoz, Oksidatif stres.

Development of impact-resistant, halogen-free, flame-retardant PBT-based composites for use in the automotive industry

Sertcan Urcan

Technology, Testing and Analytics Team Leader, Epsan Plastik

Corresponding author e-mail: sertcan.u@epsan.com

Abstract

The automotive industry is increasingly turning to lightweight, durable, and heat-resistant polymeric composite materials to reduce fuel consumption and enhance vehicle performance. Therefore, there is a growing need to develop polymeric matrix composites that can be used continuously at high temperatures while maintaining mechanical strength. In this study, the aim was to develop a new generation of polymeric composites with high impact resistance and long-term thermal stability, specifically for use in interior and exterior automotive parts. For this purpose, Polybutylene Terephthalate (PBT), an engineering plastic known for its resistance to heat and chemicals thanks to its morphological structure, was selected as the matrix material. The aim of the study was to develop halogen-free flame-retardant and impact-modified PBT composites for use in components exposed to high temperatures, such as in electric vehicles. To achieve these properties, a total of 8 different formulations containing various impact-modifying additives were prepared and tested. In addition, orange color additives, which are frequently preferred in the automotive industry to increase safety and visibility, have also been added to the formulations. Different PBT-based composite formulations were produced using a twin-screw extruder through melt compounding, and the resulting granules were shaped using injection molding. To evaluate the performance of the developed materials, a comprehensive set of mechanical, thermal, and electrical tests was conducted. Mechanical properties were assessed using tensile testing, flexural testing, and both notched and unnotched Izod and Charpy impact tests. High-temperature performance was evaluated through Heat Deflection Temperature (HDT) testing. Electrical properties were assessed with the Comparative Tracking Index (CTI). Flame retardancy was determined according to UL-94, Glow-Wire Ignition Temperature (GWIT), and Glow-Wire Flammability Index (GWFI). As a result, the developed PBT-based composites demonstrated that they can be used as cost-effective, environmentally friendly, and locally manufacturable alternatives in automotive parts that require high heat and impact resistance.

Abstract

In recent years, there has been a growing interest in polymeric materials derived from natural sources, accompanied by an expansion of their applications across various biomedical fields. This study presents an environmentally sustainable approach by incorporating both the naturally occurring polyphenol quercetin and the biopolymer alginate as components of a drug delivery system. Furthermore, the comparison between quercetin-loaded cryogel beads and gel beads holds considerable scientific importance. Alginate-based delivery systems were developed for the controlled release of quercetin. Initially, quercetin encapsulated calcium ion (Ca^{2+}) cross-linked alginate gel beads were synthesized through ionic gelation, followed by the preparation of their corresponding cryogel bead forms. Encapsulation of quercetin in alginate beads was determined and proven upon Fourier Transform Infrared (FT-IR) spectra analysis. Release kinetic studies were performed in dimethyl sulfoxide (DMSO). Kinetic analysis revealed that quercetin release from alginate cryogel beads in DMSO followed a first-order model, indicating concentration-dependent release behavior. In contrast, quercetin release from alginate gel beads conformed to the Higuchi model, suggesting diffusion-driven transport through the polymeric matrix. The 2,2-diphenyl-1-picrylhydrazyl (DPPH) assay was performed to determine the radical scavenging capacity of quercetin and compared with gallic acid as a reference material.

Keywords: Quercetin, drug delivery systems, alginate, antioxidant capacity.

Abstract

Varicellovirus bovinealpha1 is an infectious viral agent that causes respiratory and genital tract diseases in cattle, leading to severe economic losses, including reduced milk production and abortion. The gE glycoprotein is a key virulence factor that enables herpesviruses to evade immune responses and spread efficiently from cell to cell, particularly within nervous tissue. In this study, the aim was to produce and characterize the gE glycoprotein in a yeast expression system using *Pichia pastoris.* The clinical *V. bovinealpha1* virus isolate (Kayseri, 2024) was used in the MDBK cell line. The partial gE gene region encoding 210 amino acids, which contains antigenically rich epitope regions, was amplified by PCR using primers. *Eco*RI and *Xba*I restriction sites located in the multiple cloning site of the pPICZαA vector were added to the 5' ends of the primers. The obtained PCR product was ligated into the vector using T4 DNA ligase enzyme, and a recombinant pPICZAα-gE was constructed. The pPICZAα-gE was propagated and purified in *Escherichia coli* DH5α cells and transferred to *P. pastoris* GS115 by electroporation. Selection of transformants was performed on selective YPD-Sorbitol medium containing Zeocin antibiotic. Following enrichment of positive colonies in BMGY/BMMY medium, induction was carried out with 1% methanol for 96 hours. The gE glycoprotein secreted in the culture supernatant was purified with His-tag affinity resin. The presence of a protein with a molecular weight of approximately 23 kDa was observed in SDS-PAGE analysis, and the specific product was confirmed by Western blot analysis using HRP-conjugated mouse 6x-His Tag monoclonal antibody. In conclusion, we successfully expressed the gE glycoprotein in the *P. pastoris* system for protein expression, demonstrating that this system could serve as a suitable model for the recombinant production of viral glycoproteins. It was evaluated that the obtained protein could be utilized in advanced diagnostic and immunological research.

Abstract

Lavender (*Lavandula angustifolia* Mill.) is one of the most widely cultivated essential oil–producing plant species globally. In Türkiye, commercial plantations predominantly utilize cultivars originating from Bulgaria. The objective of the present study was to determine the essential oil yield, chemical composition, and enantiomeric distribution of linalool and linalyl acetate in six Bulgarian lavender cultivars (Sevtopolis, Druzhba, Yubileina, Hemus, Hebar, and Raya) cultivated in the Marmara (Thrace) region of Türkiye. For each cultivar, 15 individual plant samples were analyzed. Essential oils were extracted via hydrodistillation using a Clevenger-type apparatus. The essential oil yields were as follows: Sevtopolis 4.9%, Druzhba 5.2%, Yubileina 5.1%, Hemus 5.8%, Hebar 5.3%, and Raya 5.1%. Chemical characterization of the oils was conducted using GC–MS/FID equipped with a polyethylene glycol (wax) column. Linalool and linalyl acetate, the principal quality markers of lavender essential oil, varied among cultivars: Sevtopolis exhibited the lowest concentrations (29% linalool and 30% linalyl acetate), whereas Yubileina showed the highest (32% and 35%, respectively). Enantiomeric analysis of linalool and linalyl acetate—an important determinant of essential oil authenticity—was performed using GC–MS/FID with a chiral Cyclodex-β column (10.5% β-cyclodextrin; 60 m × 0.25 mm × 0.25 µm). The proportion of R-(–)-linalool ranged from 96.2% to 97.8% across the cultivars, while linalyl acetate consisted exclusively of the R-(–) enantiomer (100%) in all samples. The highest R-(–)-linalool content was detected in Druzhba (97.8%), whereas the lowest occurred in Hemus (96.2%). As the cultivars exhibited only minor differences in chemical composition and enantiomeric distribution, and given its comparatively high essential oil yield, Hemus appears to be the most suitable cultivar for cultivation under the environmental conditions of the Marmara region.

Keywords: Lavender, Bulgarian cultivar, Chemical characterization, Enantiomeric distribution, Chiral separation.

Abstract

Legumes are highly susceptible to post-harvest insect damage, which can reduce seed quality, weight, and germination. *Acanthoscelides obtectus* (Say, 1831) is a major pest of stored beans and other legumes. While chemical insecticides are commonly used, concerns about residues and environmental impact necessitate safer alternatives. Plant-derived fixed oils represent a promising natural control strategy. This study evaluated the insecticidal effects of *Calendula officinalis* oil and *Silybum marianum* oil on adult *A. obtectus* under controlled laboratory conditions. Experiments were conducted at 24 ± 1°C and 27 ± 1°C with 65 ± 5% relative humidity in temperature-controlled incubators.. Four different doses (100, 150, 200, and 250 µL) were applied in four replicates, each consisting of 20 adult individuals, and mortality was monitored until all individuals in the control groups had died. LT_{50} values were calculated to quantify the speed of lethal effects. Results showed clear dose–response and temperature–dependent patterns. At 24 °C, *Calendula officinalis* oil exhibited rapid mortality, particularly at 200–250 µL, whereas *Silybum marianum* oil showed moderate efficacy. At 27 °C, mortality increased for both oils, with *Calendula officinalis* oil consistently producing the fastest lethal effect across all doses. *Silybum marianum* oil's activity at 27 °C increased at higher doses (specifically at 150 µL and higher doses) but remained low at 100 µL. These findings demonstrate that elevated temperature enhances insecticidal performance and that *Calendula officinalis* oil is more potent than *Silybum marianum* oil under all tested conditions. Overall, high-dose applications of *Calendula officinalis* oil produced the lowest LT_{50} values, indicating its potential as a rapid-acting natural agent for the management of *A. obtectus* in stored legumes.

Keywords: *Acanthoscelides obtectus*, Chrysomelidae, Insecticidal potential, *Silybum marianum* oil, *Calendula officinalis* oil.

Abstract

Excessive and abnormal excess fat in the body that leads to biological health problems is called obesity With the rapid increase in obesity prevalence in recent years, obesity has become a major public health problem worldwide There are studies in the literature showing that increased BMI and abdominal obesity have an effect on prediabetes, type 2 diabetes, metabolic syndrome, hypertension and atherosclerotic diseases. Subfatin is an adipokine, and this adipokine may be a potential therapeutic target in metabolic syndrome, inflammation and obesity by regulating tissue energy homeostasis. In this context, the aim of our study is to investigate the changes in the levels of subfatin in obesity progression. For this purpose,patients with a body mass index between 18.5-24.9 kg/m2 were included in the control group, those with a body mass index between 25-29.9 kg/m2 were included in the preobese group and those with a body mass index ≥30 kg/m2 were included in the obese group.In blood samples taken from patients; fasting blood glucose, HbA1c, triglyceride,total cholesterol, HDL, LDL, ALT,AST,TSH,T3,T4 levels were determined by autoanalyzer. Subfatin peptide levels were measured by ELISA. We observed that glucose, HbA1c levels in both preobese group and obese group were significantly higher than compared to control group.We observed that HDL levels in the obese group were significantly reduced compared to the control group.Also we observed no significant change in subfatin levels between the control group and the preobese group but subfatin levels were found to be significantly higher in the obese group compared to the control group. Our findings illustrated that subfatin levels increased with obesity and were positively correlated with the high blood sugar and triglyceride values accompanying obesity, while negatively correlated with HDL.

Abstract

Leaves of *Corylus maxima* Mill. were collected from the Mersin district of Akçaabat (Trabzon, Türkiye) for microwave-assisted extraction. Hazelnut is a shrub- or tree-form plant belonging to the genus *Corylus* within the subfamily Coryloideae of the family Betulaceae, and it naturally occurs in Anatolia, the Balkans, and the Caucasus region (1,2) The collected leaves were washed several times with water to remove dust and particulate residues, then dried under suitable conditions to eliminate remaining moisture. A total of 20 g of dried and ground hazelnut leaves was mixed with 400 mL of water and shaken at room temperature for 240 minutes, followed by microwave extraction at 900 W for 2 minutes.From the obtained extract, 1 and 2 mL aliquots were taken and mixed with an aqueous solution of 0.2 mM $HAuCl_4 \cdot 3H_2O$. Gold nanoparticles (AuNPs) were synthesized by subjecting these mixtures to microwave irradiation at 90 W and 180 W for 1–30 minutes**.** Reactions between hazelnut leaf extracts and solutions containing different concentrations of Au^{3+} ions were monitored, and characteristic surface plasmon resonance (SPR) peaks were determined using UV–Visible spectroscopy. Dynamic light scattering (DLS) analyses provided particle size distribution, polydispersity index (PDI), and zeta potential measurements, enabling an assessment of stability and dispersion (3).

Abstract

Regulating cholesterol and lipid metabolism is important for maintaining cellular energy balance and cell membrane integrity. In recent years, research into the antioxidant, anticancer and metabolic regulatory effects of Schiff base derivative compounds in biological systems has intensified. The aim of our study was to determine the effects of the newly synthesised compound 4,5-dihydro-1*H*-1,2,4-triazol-5-one (3-MTA) on serum protein expression and lipid profiles under *in vivo* conditions. For this study, 28 Wistar albino rats, aged 4–5 months, were divided into four groups: a control group; a dimethyl sulfoxide (DMSO) group; a group receiving a 10mg/kg application of 3-MTA; and a group receiving a 50mg/kg application of 3-MTA. Serum protein expression was evaluated using sodium dodecyl sulfate-polyacrylamide gel electrophoresis; triglyceride, total cholesterol, high-density lipoprotein (HDL), low-density lipoprotein (LDL) and very low-density lipoprotein (VLDL) levels were determined using an autoanalyser. Following the electrophoretic evaluation, decreased 167kD protein expression and increased 62kD protein expression were observed in rats administered the 3-MTA compound at a dose of 50mg/kg, compared to the control group. A decrease in 55kD and 53kD protein expression was observed in rats administered a 10 mg/kg dose, while an increase was observed in rats administered a 50mg/kg dose. According to biochemical analysis, triglyceride and VLDL cholesterol levels increased ($P<0.001$) and LDL cholesterol levels decreased ($P<0.001$) only in rats administered a 10mg/kg dose of the 3-MTA compound compared to the control group. In conclusion, it is anticipated that the 3-MTA compound will have a positive effect on lipid metabolism and the serum protein profile. These effects are believed to be associated with the compound's potential antioxidant or hepatoprotective mechanisms. While comprehensive analyses are yet to be conducted, 3-MTA is considered a may represent a promising candidate for further investigation.

Abstract

Reactive oxygen species (ROS) generated during metabolic processes, together with environmental factors such as radiation, heavy metals, pesticides and cigarette smoke, can cause severe damage to DNA, including strand breaks, base modifications and chromosomal abnormalities. Such DNA lesions form the basis of various pathological mechanisms, including the development of mutations, disruption of the cell cycle, premature cellular senescence and malignancy. Insufficiencies in DNA repair pathways lead to the accumulation of permanent genetic alterations, ultimately compromising genomic integrity. Therefore, the protective potential of natural antioxidant compounds against oxidative stress–induced DNA damage has become a major focus of recent scientific research. Phytochemicals such as polyphenols, flavonoids and tannins can exert cellular protection by neutralizing free radicals. In this context, the present study aimed to evaluate the genotoxic and antigenotoxic effects of *Geranium robertianum* extract (GRE), commonly known as "herb robert," on the human liver cancer cell line (HepG2) under in vitro conditions using the Comet assay. In the first step, the highest non-cytotoxic concentration of GRE was determined via the Sulforhodamine B (SRB) cell viability assay, which was identified as 50 µg/mL. Subsequently, GRE was applied at concentrations of 12.5, 25 and 50 µg/mL, and DNA damage parameters were analyzed. The results demonstrated that GRE did not exhibit any statistically significant genotoxic effect at these concentrations, and notably, the 12.5 µg/mL dose significantly reduced hydrogen peroxide (H_2O_2)-induced DNA damage ($p<0.05$). These findings indicate that *G. robertianum* can prevent oxidative stress–related DNA damage without inducing genetic toxicity. Overall, the results provide a scientific basis for further pharmacological and toxicological investigations into the protective properties of plant-derived compounds and highlight the potential of *G. robertianum* as a natural antigenotoxic agent.

Keywords: *Geranium robertianum*, HepG2, Comet Assay, Genotoxicity, Antigenotoxicity, Antioxidant

Abstract

Activated carbon (AC) is widely used in different industrial applications such as industrial wastewater treatment, petrochemical industries, solvent recovery, catalyst supports, and the pharmaceutical industry. AC also has a high demand for energy storage device production, especially for supercapacitors due to the porous structure. AC contains well-developed micropores, mesopores, and macropores with various surface functional groups in their structure. AC can be classified as granule, powder, and pellet based on their shape and size. AC production can be costly, and reliance on nonrenewable resources raises sustainability concerns. This study was contained results of comprehensive investigation of publications from 2000 to 2021 related on activated carbons providing an extensive comparison of physical, chemical, and surface properties of activated carbons produced from biomass, coal, shells/seeds, woody materials, and mixed wastes. For the feedstock groups (G1–G6), key parameters including BET surface area, iodine number, total pore volume (Vt), micropore volume (Vmic), mesopore volume (Vmeso), particle size (Dp), Langmuir surface area, and pHzpc properties were evaluated. Results were demonstrated that agricultural biomass and nutshell-based raw materials can achieve high BET surface areas (1500–5000 m^2/g), with shell/seed-derived AC were showed the highest removal performance. The research results were also explored the effects of chemical activation agents (KOH, H_3PO_4, $ZnCl_2$) and physical activation methods (CO_2, steam, heat treatment). Chemical activation leads to the higher surface development, while physical activation offers cleaner surface chemistry and controlled porosity. Overall, this comprehensive evaluation was showed that the critical influence of feedstock selection, activation method, and processing conditions on activated carbon performance, providing insight into scientific trends for developing high-performance adsorbents. Adsorption on AC has long been recognized to be one of the most effective methods for the removal of pollutions such as pesticides, dyes and organic compounds from aqueous solutions.

Abstract

The production of activated carbon (AC) arises from the extensive variety of raw materials that can be utilized in its production, encompassing coal, wood, and, more increasingly, diverse forms of agricultural and industrial waste. This flexibility provides both economic and environmental advantages, especially in fostering resource circularity and waste valorization. AC is a widely utilized porous material known for its high surface area, tunable pore structure, and surface functionality, making it suitable for applications such as water and air purification, energy storage, gas separation, and catalysis. AC also eliminates undesirable odors, flavors, and colors in food products. In energy, it purifies syngas, a mixture of CO and hydrogen, from burning fossil fuels or biomass. AC serves to purify biogas by eliminating contaminants such as sulfur, chlorine, and ash from syngas, thereby enhancing its cleanliness and efficiency as a fuel source. It plays a crucial role in various energy sectors. Its substantial surface area facilitates effective adsorption and desorption of lithium ions, thereby offering a high capacity for lithium-ion storage. AC serves as a cathode material in lithium-sulfur batteries, enhancing cycling reliability by mitigating the dissolution of polysulfides. It also supports supercapacitor production, enabling rapid charge-discharge cycles. The durability, conductivity, extensive surface area, and versatility of AC render it indispensable for sustainable energy solutions and energy storage systems. Recent advancements in biochar-based composites demonstrate effective strategies for optimizing the utilization of agricultural waste while enhancing the functional properties of polymer materials. AC also highly versatile and widely used adsorbent in water treatment due to its excellent adsorption capabilities, large surface area, and well-developed pore structure. It is capable of eliminating a wide range of contaminants from water, such as organic molecules, inorganic pollutants, and new toxins, making it an important component of numerous water purification procedures. This research was analyzed Turkey's AC production and import quantities, usage sectors, and consumption distribution. According to the data, Turkey imports approximately 44 million kg of AC annually, with the majority used in drinking water treatment, wastewater treatment, food processing, gas purification, and gold recovery industries. Powdered and granular ACs are the most demanded products by municipalities and industrial facilities. The import data indicate a continuous increase in AC consumption due to the expansion of advanced water treatment technologies and industrial purification needs. Turkey's rising environmental standards and investments in water treatment systems are driving the demand for higher-performance adsorbents.

Abstract

Diabetes mellitus is a chronic disease and many people suffer from this disease. Type 2 *diabetes mellitus* is the most common type of diabetes, and more than 95% of people with diabetes have type 2 diabetes. Metformin is widely used as an oral hypoglycemic drug in the treatment of type 2 *diabetes mellitus*. It is a biguanide derived from *Galega officinalis* and is the first antidiabetic drug used in the treatment of patients with type 2 *diabetes mellitus*. Some previous reports indicated that MET has antioxidant, anti-inflammatory, antiapoptotic, and anticancer effects. The aim of this study was to determine the potential cytotoxic/anticancer effects of Metformin, which is widely used in the treatment of type 2 *diabetes mellitus*, on the human breast cancer MCF-7 cell line using the 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyl tetrazolium bromide (MTT) assay. Different concentrations of Metformin (31.25, 62.50, 125, 250, 500, and 1000 µg/mL) were treated with MCF-7 cells at a 24-hour treatment period. A negative control (distilled water) was also maintained in culture. As a result, Metformin statistically significantly reduced cell viability in MCF-7 cells at all concentrations for 24 hours of treatment compared to the control. The half of the inhibitory (IC50) value that kills fifty percent of the cells was found as 1000 µg/mL (% 52.04% cell viability) concentration for 24 h. In conclusion, Metformin exhibited cytotoxic/anticancer effect in MCF-7 cells at between 31.25 µg/mL and 1000 µg/mL concentrations.

Keywords: Metformin, antidiabetic drug, cytotoxicity, Mtt assay, MCF-7 cell line.

Abstract

Vitamin C and its derivatives play an important role in regulating oxidative stress and maintaining tissue homeostasis in skin cells. This study comparatively evaluates the antioxidant properties, cell viability, and clonogenic capacity of L-ascorbic acid and a more stable derivative, 3-O-ethyl ascorbic acid, in human keratinocyte (HaCaT) and dermal fibroblast (HDFa) cell lines. L-ascorbic acid and 3-O-ethyl ascorbic acid were tested across a concentration range of 10–1000 µg/mL using MTT assay, clonogenic assay, and DPPH radical scavenging analysis. Their effects on oxidative stress response and cellular proliferation at different concentrations were comparatively assessed. The results showed that L-ascorbic acid exhibited pronounced dose-dependent cytotoxicity at concentrations ≥250 µg/mL, reducing viability to ~53% in HaCaT and ~59% in HDFa cells. In contrast, 3-O-ethyl ascorbic acid maintained high cell viability (>95%) in both cell lines across all concentrations, demonstrating markedly higher biocompatibility under culture conditions. In the DPPH assay, L-ascorbic acid showed strong antioxidant activity (~80% inhibition), whereas 3-O-ethyl ascorbic acid displayed a more moderate yet stable radical scavenging profile (68–73%). Clonogenic assay results further highlighted the differences between the molecules. L-ascorbic acid significantly suppressed long-term colony-forming capacity in HaCaT cells and completely inhibited colony formation at 250 µg/mL. In contrast, 3-O-ethyl ascorbic acid preserved clonogenicity in keratinocytes (82–92%) and did not exhibit inhibitory effects even at high concentrations. In fibroblasts, low-dose L-ascorbic acid enhanced colony formation (137%), whereas high doses caused marked inhibition (23%). 3-O-ethyl ascorbic acid supported fibroblast colony formation at both doses (114–153%). Although L-ascorbic acid possesses strong antioxidant capacity, its low stability leads to cellular stress, limits long-term proliferative potential, and induces cytotoxicity at high concentrations. Conversely, 3-O-ethyl ascorbic acid offers a more advantageous biomolecular profile for skin biology and advanced dermocosmetic applications due to its high biocompatibility, stable antioxidant response, and ability to preserve clonogenic capacity.

Özet

Biyotik stres faktörleri, kabakta (*Cucurbita pepo*) verimliliği önemli ölçüde sınırlar. Bitki savunmasında gen ifadesini post-transkripsiyonel modüle eden mikroRNA'ların (miRNA), strese yanıt veren gen ifadesindeki rolü kritiktir. Bu çalışmada, *C. pepo*'daki biyotik stresle ilişkili miRNA'ların ve düzenleyici işlevlerinin kapsamlı biyoinformatik analizlerle karakterize edilmesi amaçlanmıştır. Çalışmada, *C. pepo*'ya ait kamuya açık genom ve transkriptom veri setleri analiz edilmiştir. Potansiyel miRNA'ların tespiti için miRBase referans veritabanı ile homoloji tabanlı arama, miRDeep2 yazılımı ile RNA-Seq verilerinden *de novo* tahmin ve BLAST ile doğrulama stratejileri uygulanmıştır. Tanımlanan miRNA adaylarının ikincil yapıları RNAFold ve UGENE, filogenetik analizi MEGA ve hedef genleri ise psRNATarget sunucusu aracılığıyla belirlenmiştir. Son olarak, hedef genlerin biyolojik rolleri ve ilişkili metabolik yolaklar, Gene Ontology (GO) ve KEGG analizleri ile aydınlatılmıştır. Analizler sonucunda, *C. pepo*'da; *miR156*, *miR157*, *miR160*, *miR166*, *miR167*, *miR168*, *miR171*, *miR172*, *miR390*, *miR395*, *miR397*, *miR398* ve *miR399* ailelerine ait 19 anlamlı miRNA tanımlanmıştır. Fonksiyonel anotasyon bulguları, bu miRNA'ların savunma yanıtı, programlı hücre ölümü, hormon sinyalizasyonu (oksin, SA, JA, ET) ve redoks dengesiyle ilişkili genleri potansiyel olarak düzenlediğini göstermiştir. Hedef genlere ilişkin GO analizi; *miR397* (%33,3), *miR166* (%23,3), *miR398* (%23), *miR399* (%13), *miR160* (%12.1) ve *miR172* (%11) ailelerinin biyotik stres yanıtıyla ilişkili en anlamlı miRNA'lar olduğunu ortaya koymuştur. KEGG analizleri ise hedef genlerin; alfa-linolenik asit, sülfür, fenilpropanoid ve flavonol biyosentezi gibi biyotik strese dirençle ilişkili 25 farklı metabolik yolağa katıldığını ortaya koymuştur. Bu bulgular, *C. pepo*'nun biyotik strese yanıtında rol oynayan moleküler düzenleyici ağlara yönelik mevcut bilgi birikimine katkı sağlamakta ve direnç ıslahı ile stres adaptasyon kapasitesi yüksek çeşitlerin geliştirilmesine yönelik çalışmalarda kullanılabilecek olası miRNA–gen etkileşim modüllerini tanımlamaktadır.

Anahtar Kelimeler: *Cucurbita pepo*, mikroRNA, biyotik stres, psRNATarget, fonksiyonel anotasyon, gen düzenlemesi.

Abstract

Diabetes mellitus is a chronic metabolic disorder characterized by persistent hyperglycemia arising from impaired insulin secretion or action [1]. Its global prevalence continues to increase at an alarming rate, leading to substantial healthcare expenditures and a growing socioeconomic burden [2]. Current antidiabetic drugs, particularly α-amylase and α-glucosidase inhibitors used to control postprandial hyperglycemia, are often associated with adverse gastrointestinal effects such as abdominal discomfort, diarrhea, and flatulence, which limit long-term patient compliance . Therefore, the development of novel therapeutic agents with improved efficacy and reduced side effects has become an essential priority in diabetes management. In recent years, silicon phthalocyanines have gained attention due to their tunable electronic properties, high chemical stability, ease of axial functionalization, and promising applicability in biological systems, making them suitable candidates for enzyme-targeted drug design [3]. In this study, morpholine-functionalized axially disubstituted silicon phthalocyanines and their water-soluble derivatives were synthesized as potential antidiabetic agents. The structures of the newly obtained compounds were elucidated using FT-IR, NMR, and mass spectrometry. The inhibitory activities of the phthalocyanines were evaluated against the carbohydrate-digesting enzymes α-amylase and α-glucosidase. All derivatives exhibited weak α-amylase inhibition (IC_{50} > 100 μM), showing lower activity than the reference drug acarbose (IC_{50} = 25.29 ± 3.50 μM). In contrast, pronounced inhibition was observed against α-glucosidase: the nonionic analogues MT-C3-H-Si and MT-C3-D-Si showed IC_{50} values of 16.02 ± 0.94 μM and 44.14 ± 4.06 μM, respectively, surpassing acarbose (IC_{50} = 60.51 ± 4.66 μM). Kinetic analyses using Lineweaver–Burk plots revealed a non-competitive inhibition mechanism, indicating allosteric interaction with the enzyme. These results demonstrate that morpholine-substituted silicon phthalocyanines particularly the nonionic derivatives possess promising α-glucosidase inhibitory properties and may serve as valuable leads for the development of new antidiabetic agents with reduced side effects.

Abstract

Analyzing trends in water quality parameters has become essential for understanding the long-term dynamics of aquatic environments and ensuring the sustainability of water resources. Research across rivers, lakes, estuaries, and coastal waters consistently shows that indicators such as dissolved oxygen, pH, nutrients, salinity, and hardness exhibit temporal variations shaped by both natural cycles and human pressures. Evidence from diverse geographic contexts reveals recurring patterns: seasonal fluctuations driven by hydrological regimes, gradual declines associated with urbanization, agriculture, and industry, and localized improvements following targeted management actions. Such analyses function not only as descriptive assessments but also as early warning systems for ecological degradation, diagnostic tools for identifying pollution sources, and benchmarks for evaluating intervention effectiveness. Synthesizing outcomes from multiple case studies demonstrates that continuous monitoring and evaluation of water quality are indispensable for protecting ecosystem health, maintaining reliable water supplies, and guiding adaptive responses to climate change and population growth. Collectively, the accumulated evidence highlights the pivotal role of trend analysis in connecting scientific knowledge with practical water management, offering a comprehensive perspective on the condition of aquatic systems and pathways toward their sustainable future.

Abstract

Groundwater is a natural resource that is vulnerable to pollution, particularly in basins with intensive agricultural activities. In this study, the groundwater vulnerability of the Develi Basin, located within the boundaries of Kayseri Province, was evaluated using the GIS-based DRASTIC method. The analysis includes seven key hydrogeological parameters: Depth to Water Table (D), Net Recharge (R), Aquifer Media (A), Soil Media (S), Topography (T), Impact of the Vadose Zone (I), and Hydraulic Conductivity (C). Well logs provided by the State Hydraulic Works was used to estimate depth to water table. Net recharge was obtained from a previous study that used Soil and Water Assessment Tool to simulate basin hydrology. Aquifer media, soil media, impact of vadose zone, and hydraulic conductivity were estimated based on national soil and geological maps. Information on topography was obtained from a digital elevation model of the study area. All maps were were generated in raster format with a 100-meter cell size and classified and rated according to standard DRASTIC criteria. The resulting DRASTIC Index (DI) values were classified into vulnerability categories ranging from Low to Very High. Spatial analysis shows that the central part of the plain, characterized by alluvial deposits, shallow groundwater levels, and high hydraulic conductivity, falls within the “Very High” vulnerability class. In contrast, the basin margins with steeper slopes show “Low” vulnerability. These findings show the areas most susceptible to contamination and provide basis for managing potential pollution risks in the Develi Basin.

Abstract

Metal nanoparticles (MNP) can be prepared using physical, chemical, or biological methods. The use of biological methods, known for their enhanced energy efficiency and environmental sustainability, is steadily growing. Bimetallic nanoparticles (NPs), on the other hand, have recently become more interesting than their monometallic counterparts thanks to their advanced properties emerging from the synergistic effect of two metals, and prompting increased research on the subject. This study indicates the synthesis and characterization of monometallic (Ag and ZnO) and bimetallic (Ag-ZnO) NPs using water-soluble cassava starch. Mono- and bimetallic NPs were synthesized using cassava starch. The formation of NPs was analyzed through techniques such as Fourier transform infrared spectroscopy (FTIR), Ultraviolet–visible spectroscopy (UV-Vis), and Transmission electron microscopy (TEM). FTIR confirmed the presence of functional groups in all prepared NPs. TEM images revealed that all NPs had a sphere-like morphology larger than 20 nm and were well separated from each other. In sum, the results showed that mono- and bimetallic NPs can be rapidly synthesized from cassava starch without the use of toxic reducing agents. This underscores the prioritization of NP production using eco-friendly routes.

Keywords: Bimetallic nanoparticles, green synthesis, silver nanoparticles, zinc oxide nanoparticles.

Abstract

Borax decahydrate (disodium tetraborate decahydrate) is one of the tincal derivatives and is widely used as an additive in many industrial sectors, such as agriculture, detergents, glass, ceramics, and cosmetic products. According to previous studies, boric acid and its derivatives have shown important biological effects such as potential antioxidant, anti-inflammatory and anticancer. However, studies on human lymphocytes regarding genotoxic potential are limited. The aim of this study is to evaluate the potential genotoxic effect of borax decahydrate using the micronucleus assay in human peripheral blood lymphocytes *in vitro*. This research was approved by the Gazi University Faculty of Medicine Ethics Committee (01.08.2025/137). Lymphocyte cultures were treated with five different concentrations of borax decahydrate (2.5, 5, 10, 20, and 40 µg/mL) for 48 hours. A negative (distilled water) and a positive control (Mitomycin-C, 0.20 µg/mL) were conducted in culture. According to the results, none of the studied concentrations of borax decahydrate caused a significant increase in the frequency of MN between 2.5 µg/mL and 40 µg/mL concentrations compared to the control. Additionally, borax decahydrate did not affect nuclear division index (NDI) at any treatment. These findings indicate that borax decahydrate did not exhibit genotoxic or cytotoxic effects in human peripheral lymphocytes under the tested concentrations in *in vitro* conditions.

Keywords: Borax decahydrate, micronucleus assay, nuclear division index, human peripheral lymphocytes.

Abstract

In recent years, the rise in diabetes, obesity, and metabolic disorders has encouraged individuals to reduce sugar consumption, increasing interest in low-calorie artificial sweeteners. These compounds are widely used, particularly in diet products, as they provide sweetness with minimal caloric intake. Among them, Aspartame (ASP; E-951) is a prominent additive due to its nearly 200 times sweeter taste, low cost, and broad applicability. However, recent studies suggest that long-term aspartame intake may be associated with insomnia, loss of consciousness, cardiovascular disturbances, increased diabetes risk, and potential adverse effects on the nervous system. In 2023, the International Agency for Research on Cancer (IARC) classified aspartame as "probably carcinogenic" to humans (Group 2B), emphasizing the need for careful evaluation of its safety. In contrast, boric acid (BA) has gained attention in toxicology research, as its antioxidant, antiviral, anti-inflammatory, antibacterial, and antigenotoxic properties contribute to cellular protection against oxidative stress. This study aims to investigate the protective/antigenotoxic potential of boric acid against the genotoxic effects induced by aspartame using the cytokinesis-block micronucleus (SB-MN) test. Human peripheral lymphocytes were treated simultaneously (ASP+BA) for 48 hours with various concentrations of aspartame (0.125, 0.25, 0.50, and 1 µg/mL) alone and with BA (0.0313, 0.0625, 0.125, and 0.25 µg/mL) for 48 hours. ASP significantly increased the micronucleus-MN frequency at 0.50 and 1 µg/mL ($p<0.01$ and $p<0.05$). In the concurrent application, BA achieved a significant improvement ($p < 0.05$) in the MN frequency induced by aspartame at 0.5 µg/mL across all concentrations (50-59%). BA significantly improved the MN frequency ($p<0.01$ and $p<0.05$) at 0.125 and 0.250 µg/mL (61-72%). These results suggest that boric acid may have the potential to improve the genetic hazard induced by aspartame. However, more detailed in vitro and in vivo analyses are needed to understand this effect better.

Abstract

Breast cancer is the most frequently diagnosed cancer among women worldwide and remains a major cause of cancer-related mortality. Chemotherapy, despite being a mainstay treatment, often leads to severe systemic toxicity and damage to healthy tissues, highlighting the need for safer therapeutic strategies. Phytochemicals, as bioactive molecules, suppress oncogenic pathways and induce apoptosis, offering potential as supportive or complementary agents. Epigallocatechin gallate (EGCG), abundant in green tea, demonstrates low toxicity and multiple molecular targets, suggesting that its combination with chemotherapeutics may enhance efficacy by modulating distinct cellular pathways. This study evaluated the cytotoxic effects of Capecitabine combined with EGCG on the human breast cancer cell line SK-BR-3. IC50 values were determined for both agents at 24 and 48 hours. Based on these values, the combined treatment was assessed using the Chou–Talalay combination index, which demonstrated synergistic interaction, particularly at 48 hours. The enhanced cytotoxic activity of the combination was further supported by wound-healing and DAPI staining assays. Quantitative wound-healing analysis revealed that cell density in the control group increased from an initial 23% to 37.5% at 48 hours, whereas the combination treatment showed only a slight change from 25% to 26%, confirming markedly reduced cell motility and viability. In conclusion, this study demonstrates that combining Capecitabine with EGCG enhances cytotoxic activity in SK-BR-3 cells and supports the potential of integrating phytochemicals with chemotherapeutic agents to develop more effective breast cancer treatment strategies.

Comparison of *in silico* tools used for predicting the functional effects of polymorphisms in veterinary genetics

Dina Bedik (Orcid: https://orcid.org/0000-0002-4088-3827)

Istanbul University-Cerrahpasa, Faculty of Veterinary Medicine, Department of Veterinary Biochemistry, Istanbul, Türkiye

Corresponding author e-mail: dina.bedik@iuc.edu.tr

Abstract

Accurate prediction of the functional consequences of single nucleotide polymorphisms (SNPs) is essential for elucidating disease mechanisms and enhancing genomic selection strategies in veterinary genetics. Despite their widespread use, in silico prediction tools differ significantly in their algorithmic frameworks, scoring systems, and output formats. This study presents a methodological comparison of six commonly applied prediction tools (SIFT, PolyPhen-2, PROVEAN, PANTHER, MutPred2, and PredictSNP) by examining their computational principles, data dependencies, evaluation criteria, and relevance to veterinary genetic research. SIFT, PROVEAN, and PANTHER primarily rely on evolutionary conservation and sequence homology to infer the tolerance or deleteriousness of amino acid substitutions. PolyPhen-2 expands upon this by integrating structural features, functional domains, steric constraints, and biophysical parameters, thereby providing a more comprehensive assessment. MutPred2, based on deep learning, not only predicts variant pathogenicity but also offers mechanistic insights into potential molecular alterations. As a meta-predictor, PredictSNP synthesizes outputs from multiple tools to generate consensus scores and serves as a robust benchmark for comparative analyses. This methodological evaluation delineates the theoretical foundations, operational characteristics, and limitations of major in silico prediction platforms, thereby establishing a conceptual basis for their application in veterinary genetics. This evaluation will provide a foundation that enables researchers to identify the most appropriate in silico method based on their study objectives, the characteristics of the species being analyzed, and the structure of the available data, and will offer a general perspective on method selection in functional variant analyses.

Keywords: genetics, *in silico*, prediction, SNP, veterinary

Abstract

Parasitic diseases are one of the most significant problems today. Parasitic diseases cause serious productivity losses in farm animals, especially in low-income and middle-income countries. In addition, zoonotic parasitic diseases complicate treatment protocols in co-infections and lead to serious public health problems by altering host immune responses. Many traditional antiparasitic control methods have been used for many years to combat these problems. However, these methods have many disadvantages. These include insufficient sensitivity in microscopy and serology, long diagnostic turnaround times, obstacles posed by complex treatment regimens in the management of co-infections with immunosuppressive diseases such as HIV, antiparasitic drug resistance development, residues and environmental toxicity, low bioavailability, and off-target effects. In recent years, scientific studies on new formulations and diagnosis, treatment, and control methods have gained momentum by utilizing biotechnological and nanotechnological capabilities to overcome these limitations. This review summarizes the current status, potential shortcomings, and future prospects of biotechnological and nanotechnological approaches in parasitology, summarizing the interesting developments and scientific studies reported in recent years.

Abstract

The genus Salmo, within the family Salmonidae, contains fish species that are difficult to distinguish due to their similar morphological characteristics. The taxonomic classification of Salmo species, both globally and in Turkey, remains controversial. Mitochondrial DNA is used by researchers in phylogenetic studies to elucidate evolutionary connections between different species. Despite its widespread use in prokaryotic phylogenetics, applications of secondary structure analysis in eukaryotes such as fish remain largely unexplored. This study aims to exploit differences in molecular folding structures to elucidate evolutionary relationships among various fish species using structural data obtained from existing mitochondrial gene regions. We anticipate that the secondary structures of biomolecules in different fish species can illuminate phylogenetic relationships between species. In this regard, we analyzed the secondary structures of the 12S (approximately 170 sequences;~600 bp), 16S (approximately 220 sequences;~400 bp), and Cty-b (approximately 1200 sequences;~800 bp) mitochondrial gene regions found in the NCBI database. The rRNA regions included in the analysis revealed variability in the RNA folding models obtained in all fish species studied. Based on the obtained rRNA models, 751 conserved regions were identified in the 12S rRNA, 1337 in the 16S rRNA, and 252 in the Cyt-b region. Additionally, 77 conserved stem regions were observed in the 12S rRNA sequences and 86 in the 16S rRNA sequences. In conclusion, the secondary structures of the gene regions used in the classification of Salmo species may be a potential tool for distinguishing closely related species. Furthermore, the secondary structure of RNA can provide additional taxonomic information, especially in the case of closely related species.

Abstract

Kütahya has a very complex geological structure with abundant sedimentary and volcanic rocks. This complex structure results in this region being rich in various elements. This situation significantly affects the water quality of the region. In this study, it was aimed to determine some physicochemical parameters and metallic element amounts of drinking water in Kütahya province and surrounding villages and to investigate their effects on human health. Knowing the quality of the water consumed by a person who needs to consume an average of two liters of water a day is very important for human health. In the study, temperature, pH, electrical conductivity (EC), total dissolved solids (TDS), salinity, nitrate (NO_3), nitrite (NO_2), phosphate (PO_4) and ammonia (NH_3) values were measured from the physicochemical parameters. In addition, the amounts of magnesium (Mg), zinc (Zn), copper (Cu), cadmium (Cd), lead (Pb), cobalt (Co), silver (Ag), iron (Fe), manganese (Mn), calcium (Ca), potassium (K), and sodium (Na) elements were determined. The findings obtained from the study were compared with the Turkish Standards Institute Regulation on Water Intended for Human Consumption, the World Health Organization (WHO), and the European Environment and Protection Agency (EPA) standard values. When the physicochemical parameters and heavy metal values obtained from the study are examined, it can be said that the drinking water of Kütahya Province and its surrounding villages does not pose any risk to human health, although some high values were detected.

Keywords: Drinking water, human health, Kütahya, metallic element, physicochemical parameters.

Abstract

The aim of this study was to elucidate the effects of low-temperature stress on the organization and compositional dynamics of the pollen tube cell wall in *Camellia sinensis*. Accordingly, pollen grains subjected to low-temperature treatments were germinated at 5, 10, and 15 °C, whereas the control group was maintained at ambient temperature, with all samples incubated for 4 h in a standardized germination medium containing 8% sucrose. At the pollen tube apex, the distribution of pectin exhibited a significant increase only following the 10 °C treatment relative to the control. Along the tube, pectin distribution in the 15 °C group displayed a profile comparable to the control, whereas deviations were evident in both the 10 °C and 5 °C groups. The distribution of esterified pectin at the tube apex showed a significant increase exclusively in the 15 °C group compared with the control. However, along the tube, the 10 °C and 5 °C treatments resulted in noticeable departures from the control pattern. With regard to de-esterified pectin, a significant increase at the tube apex was observed solely in the 5 °C group. Although all temperature treatments caused deviations from the control along the tube, the most pronounced alterations were detected at 10 °C and 5 °C. Callose distribution at the tube apex significantly increased in all treatment groups relative to the control. Along the tube, numerical variations were observed under all conditions; however, the 15 °C and 10 °C groups demonstrated control-like distribution patterns, whereas the 5 °C group showed a distinctly divergent profile. The distribution of cellulose at the tube apex displayed a significant increase across all temperature treatments compared with the control. Although numerical fluctuations were present along the tube in all groups, the overall distribution profiles remained largely consistent with that of the control. Overall, these findings enhance our understanding of cell wall remodeling under low-temperature conditions and contribute to a better understanding of how such structural modifications influence pollen tube elongation in a cold-stressed environment. This work was financially supported by the Marmara University Scientific Research Projects Commission (Project no: FYL-2025-11603).

Abstract

The genus *Vincetoxicum* Wolf (Apocynaceae:Asclepiadoideae), which is naturally distributed in Africa, Australia, Asia, and Europe, comprises approximately 140 species that grow in various habitats[1,2]. Some species of the genus have been traditionally used to treat wounds, bone fractures, snake/insect bite, scorpion sting, and inflammation[2]. *Vincetoxicum* is one of the largest genera of the subfamily in Anatolia, represented by 10 taxa[3]. *Vincetoxicum fuscatum* subsp. *fuscatum* (Hornem.) Reichb. is known as "gavur biberi" in Turkey[4]. This study aims to investigate the total phenolic and flavonoid contents, and the antioxidant potential of ethanol extract of *V. fuscatum* subsp. *fuscatum* seeds growing wild in Turkey. The total phenolic and total flavonoid contents were investigated using Folin-Ciocalteu and aluminum chloride colorimetric assay methods, respectively. Antioxidant activity was evaluated using the DPPH radical scavenging assay. The total phenolic and total flavonoid contents of the seeds were determined as 7.42±0.035 mg GAE/g seed and 3.08±0.003 mg QE/g seed, respectively. The antioxidant activity results were expressed in both percentage inhibition (%) and mM equivalents of Ascorbic acid (AAE) per g of seeds (27.3±0.01 % and 0.26±0.06 mM AAE/g seed, respectively). This is the first study performed on the total phenolic and total flavonoid contents, as well as the antioxidant potential of *V. fuscatum* subsp. *fuscatum* seeds. Our results indicate that the tested seeds contain both phenolic and flavonoid compounds and possess antioxidant potential.

Keywords: *Vincetoxicum fuscatum* subsp. *fuscatum*, seed, total phenolic content, total flavonoid content, DPPH, Apocynaceae.

Abstract

Endometriosis is defined as the presence of tissue that mimics the endometrium in locations outside the uterine cavity.[1] A biopsy is required for definitive diagnosis. The pathophysiology and effective treatment of endometriosis remain unclear. There are no in vivo studies providing safe and definitive results in the treatment of endometriosis. Therefore, in vivo studies on its pathogenesis and treatment are crucial. Thymoquinone is a monoterpene, a primary component of Nigella sativa (black cumin) seed. Numerous studies have found thymoquinone to possess antibacterial, antitumor, antioxidant, and anti-inflammatory properties. No studies have been found evaluating the anti-inflammatory of thymoquinone in the endometriosis model, where oxidative stress and inflammation are implicated in its pathogenesis. Therefore, the present study investigated the beneficial effects of thymoquinone in preventing damage in an experimental rat endometriosis model at the cytokine levels.According to the results, while cytokine levels (IL-1,IL-1 B,IL-6,IL-10,TNF-a, NFK-B) increased in the damaged group in which the endometriosis model was created, these levels decreased significantly in the treatment group.

Keywords: Endometriosis, Thymoquinone

Abstract

Childhood vaccination remains one of the most effective public-health interventions worldwide, yet recent global trends show increasing vaccine hesitancy in several countries. Understanding how high immunisation performance can coexist with declining public trust is essential for identifying future vulnerabilities. This study examines a "coverage–confidence paradox" in Turkey by integrating childhood vaccination data, unvaccinated child counts, vaccine-confidence indicators, and child health outcomes using publicly available datasets from WHO–UNICEF, the Wellcome Global Monitor, and UN IGME accessed through Our World in Data. Childhood vaccination coverage for core EPI antigens has remained high for more than a decade: between 2014 and 2023, DTP3 coverage ranged from 95% to 99%, and full measles vaccination (MCV2) remained consistently above the global average by 17–77 percentage points (mean difference: +40). Over the same period, the number of one-year-olds unvaccinated for DTP3 fell from hundreds of thousands in the early 2000s to approximately 11,000–26,000 in recent years, with a transient pandemic-associated increase in 2021. Despite this strong programme performance, public confidence has declined. Survey data show that the share of respondents agreeing that vaccines are important for children fell from 95% in 2015 to 68% in 2023, while those disagreeing increased from 3% to 27%. Agreement that vaccines are effective declined from 89% to 68%, and the proportion considering vaccines unsafe rose from 17% to 38%, even as measles coverage increased. In global "importance vs effectiveness" scatters, Turkey's 2023 confidence levels lie at the lower end among high-coverage countries. These findings indicate a divergence between high, stable coverage and declining trust, suggesting potential vulnerability to localised susceptibility pockets and future outbreaks. Strengthening communication, community engagement, and trust-building interventions is critical to sustaining the long-term resilience of Turkey's childhood immunisation programme.

Abstract

In this study, three different bacterial isolates known to stimulate the production of secondary metabolites and to reduce respiration by inactivating ethylene synthesis were used. The effects of these bacterial isolates on the quality parameters of 'Caldesi 85' nectarine fruits during cold storage were investigated. Fruits harvested at commercial maturity were treated on the same day with control (water only), 1-MCP (positive control), and the bacterial isolates GBF70, GBF72, and RC521 (1×10^7 cfu/ml). Following immersion in the respective solutions, the fruits were air-dried, placed in plastic crates containing trays, and stored for 45 days under normal atmospheric conditions at 0 ± 0.5 °C and 90 ± 5% relative humidity. Quality parameters including flesh firmness (N), weight loss (%), soluble solids content (°Brix), titratable acidity (TA, % citric acid), ground color (Hue°), and total phenolic content (mg GAE 100 g^{-1}) were assessed at harvest and at 15-day intervals throughout storage.
The results indicated that the RC521 isolate was as effective as 1-MCP in maintaining fruit firmness and reducing weight loss, and even outperformed 1-MCP particularly in minimizing weight loss. Overall, the findings suggest that bacterial treatments may offer a more sustainable and environmentally friendly alternative to chemical methods for reducing postharvest quality losses in nectarines.

Abstract

Diabetic nephropathy (DN) is characterized by progressive renal damage driven by chronic inflammation, oxidative stress and altered molecular signaling. Identifying biomarker patterns associated with albuminuria progression is essential for improving early diagnosis and clinical follow-up. Aim of the study to investigate inflammatory cytokines, pro-resolving lipid mediators and circulating miRNA-29c expression across different stages of DN. A total of 160 people were included in the study: 40 healthy controls, 40 with type 2 diabetes, 40 with microalbuminuria, and 40 with macroalbuminuria. Serum TNF-α, IL-6 and Lipoxin A4 (LXA_4) concentrations were measured by ELISA. Circulating miRNA-29c levels were quantified by RT-PCR following RNA isolation and cDNA synthesis. TNF-α and LXA_4 levels varied significantly between groups; TNF-α gradually increased ($p \leq 0{,}001$), while LXA_4 decreased, in relation to the severity of albuminuria ($p \leq 0{,}05$). Although IL-6 values were apparently increased in the DN groups compared to the control group, there was no statistical significance. miRNA-29c expression was significantly elevated in microalbuminuria and macroalbuminuria groups ($p \leq 0{,}001$) while there was not statistically difference between controls and type 2 diabetic group, but . miRNA-29c also showed a strong positive correlation with ACR (albumin creatine ratio), fasting glucose, and HbA1c. The combined biomarker profile demonstrated a shift toward increased inflammatory activity, reduced LXA4 capacity and increased miRNA-mediated regulatory changes as DN progressed. The parallel evaluation of inflammatory mediators and circulating miRNA-29c provides a comprehensive overview of biochemical and molecular alterations associated with early renal impairment. These biomarkers may support improved risk stratification and contribute to the development of multimodal diagnostic approaches in diabetic nephropathy.

Abstract

Bacillus cereus is an important foodborne pathogen encountered in many foods, such as milk and milk-based desserts, due to its ability to form spores and its heat resistance. This study, aimed to investigate the presence of *B. cereus* in milk and milk-based desserts offered for sale in Ankara province, and to determine the distribution of important toxin genes in isolates by multiplex PCR method. Between January and March 2024, a total of 123 samples were collected from different retail outlets, including 23 raw milk, 20 pasteurized milk, 20 UHT milk, 20 rice pudding, 20 pudding, and 20 kazandibi. *B. cereus* was isolated in the samples by classical culture techniques, and suspicious colonies were confirmed by PCR targeting the hemolysin gene. The *presence of hbl*, *nhe*, *cytK* and *ces* toxin genes in the confirmed isolates was investigated by multiplex PCR. As a result of the analysis, *B. cereus* was isolated in a total of 44 samples, including 14 (60.87%) in raw milk, 8 (40%) in pasteurized milk, 2 (10%) in UHT milk, 9 (45%) in rice pudding, 3 (15%) in pudding and 8 (40%) in kazandibi. It was determined that 28 (63.63%) of these isolates had at least one enterotoxin gene, the most common of these genes was *nhe*, followed by *hbl* and *cytK* genes. The *ces* gene responsible for the emetic form was not detected in any isolate. The presence of enterotoxigenic *B. cereus* in milk and milk-based desserts poses a risk to public health, especially in cases where production and storage conditions are inadequate. These findings show that strengthening hygiene practices and reducing sources of contamination at all stages from farm to table *is critical in reducing food safety risks from B. cereus.*

Abstract

Flavonoids, a class of polyphenols, possess carbonyl and hydroxyl functional groups that enable them to bind with metal ions. In this work, curcumin and quercetin were complexed with magnesium and calcium divalent cations to improve their solubility. The antiproliferative and antioxidant properties of these complexes were evaluated using HCT-116 colon carcinoma cells. Structural characterization of the curcumin and quercetin metal complexes was carried out through TOF mass spectrometry, FT-IR, and UV-Vis analyses. A solubility assay confirmed enhanced dissolution of both compounds following complexation. Cell viability was assessed using the Cell Viability Detection Kit-8 (CVDK-8). Radical scavenging capacity was examined using the DPPH assay. Results from the viability and ROS assays indicated that curcumin and its metal complexes exerted stronger antiproliferative effects at lower doses than the quercetin complexes. Conversely, quercetin complexes demonstrated superior radical-scavenging performance in the DPPH assay. Overall, curcumin and quercetin metal complexes may offer promising avenues for improving solubility and exploring new strategies in cancer prevention and therapy.

Keywords: Flavonoids, curcumin, quercetin, ROS, and metal complexes.

Abstract

Lung cancer, the second leading cause of cancer-related deaths, is a major global health concern that affects millions of people worldwide. It has extremely low survival rates, with only 28.4% of patients remaining alive (1). Recent data have demonstrated that Bcl-2 overexpression occurs in lung cancer and is associated with poor prognosis. ABT-737 and ABT-263 are two Bcl-2 inhibitors that exhibit potent antitumoral effects against lung cancer (2,3). In addition, nuclear factor-kappaB (NF-κB), which contributes to Bcl-2 upregulation, represents another attractive therapeutic target. Because NF-κB suppresses apoptosis and promotes proliferation, invasion, and metastasis, its inhibition offers an effective treatment strategy. Previous studies have reported that inhibition of NF-κB suppresses survival and proliferation of lung cancer cells. Bortezomib, an FDA-approved anticancer agent used in several malignancies, acts as an NF-κB inhibitor (4,5). Moreover, several natural compounds, including curcumin and piperlongumine, exhibit inhibitory effects on NF-κB. Preliminary findings from our previous study indicated that amino acid derivatives show selective cytotoxic potential against A549 lung cancer cells. In the present study, we aimed to design and synthesize amino acid-hydrazone hybrids (5a–c) as dual Bcl-2/NF-κB inhibitors for lung cancer treatment (Figure 1). The compounds were evaluated against A549 lung cancer cells and Beas-2b normal bronchial epithelial cells. Among them, compound 5c was identified as the most promising molecule, exhibiting an IC_{50} value of 7.7 µM against A549 cells and a high selectivity index with an IC_{50} value of >100 µM against Beas-2b cells. Molecular docking studies were also performed against both Bcl-2 (PDB ID: 4MAN) and NF-κB (PDB ID: 1NFK). All compounds showed favorable inhibitory potentials and strong interactions with key amino acids in both targets. These findings suggest that amino acid-hydrazone hybrids have the potential to act as selective anticancer agents through dual inhibition of Bcl-2 and NF-κB, two key anti-apoptotic pathways involved in lung cancer progression.

Özet

Kalp yetmezliği, kardiyak yapı veya fonksiyondaki bir veya daha fazla anormalliğin kalbin hücresel metabolizma için gerekli olan yeterli oksijeni iletememesine yol açtığı yaşamı tehdit eden kronik bir durumdur.[1] Kalp yetmezliğini önlemenin en etkili yolu, sağlıklı yaşam biçiminin yaşam boyu teşvik edilmesi olmakla birlikte, farmakolojik tedavi, kardiyovasküler hastalıkların yönetiminde temel bir rol oynamakta ve etkili ilaç kullanımına olan gereksinimi artırmaktadır. Kalp yetmezliği olan ve kardiyovasküler olay riskinin yüksek olduğu hastalarda kombine tedaviler uygulanmaktadır. Sakubitril (SAC) ve valsartan (VAL), kronik semptomatik kalp yetmezliği olan hastalarda morbidite ve mortaliteyi azaltmak için kullanılan anjiyotensin reseptör-neprilisin inhibitörleridir.[2] ATR ile SAC-VAL kombinasyonunun koroner kalp hastalığı ve kalp yetmezliği olan bireylerde kardiyak fonksiyon ve inflamatuar belirteçler üzerinde olumlu etkiler göstermektedir.[3] Bu bulgu, aynı anda kullanılan bu üç bileşiğin eş zamanlı analizinin klinik ve farmasötik açıdan önemini ortaya koymaktadır. Bu çalışmada, ATR, SAC ve VAL yapay serum matriksinde eş zamanlı kantitatif analizini sağlayan yeni bir YPSK yöntemi geliştirilmiştir. Ayrım C18 kolon kullanılarak sağlanmıştır. Mobil faz olarak %0.1 trifloroasetik asit içeren su:asetonitril:metanol çözücü sistemi kullanılmıştır. Akış hızı 1.1 mL/dk olarak ayarlanmıştır. Analitlerin ölçümü floresans dedektör ile gerçekleştirilmiştir. Metodun doğruluk, kesinlik, özgüllük, doğrusal aralık, LLOQ ve ULOQ parametreleri ICH M10 kılavuzuna göre değerlendirilmiş ve kabul edilebilir sınırlar içinde bulunmuştur. Geliştirilen yöntem ile ATR, SAC ve VAL etken maddelerinin yapay serum matriksindeki pikleri arasında yeterli rezolüsyon elde edilmiştir. Analitlerin birbirleriyle ve matriks bileşenleriyle girişim yapmadığı bir kromatografik sistem oluşturulmuştur. Bu çalışma, birlikte kullanılan kardiyovasküler ilaçların farmasötik kalite kontrolü ve terapötik ilaç düzeyi izlemine yönelik güvenilir, duyarlı ve tekrarlanabilir bir analitik yöntem sağlamaktadır.

Anahtar kelimeler: YPSK, Atorvastatin, Sakubitril, Valsartan, Validasyon

Abstract

In this study, a new copper(II) complex containing 1,2,3-triazole ligands was successfully synthesized and structurally characterized. The ligand (ethyl 2-(4-((4-formyl-3-hydroxyphenoxy)methyl)-1H-1,2,3-triazol-1-yl)acetate) was synthesized *via* a Cu(I)-catalyzed click reaction following our previously reported procedure [1] and subsequently complexed with copper(II) acetate to obtain the target coordination compound. The structure of copper(II) complex was elucidated through various analytical techniques including melting point determination, FTIR spectroscopy, UV-Vis. spectroscopy, elemental analysis, magnetic moment measurements, MALDI-TOF-MS and single crystal X-ray diffraction (SCXRD) studies. FTIR spectroscopy revealed characteristic shifts in carbonyl and C-O stretching bands, confirming the O-coordinated binding mode. UV-Vis data exhibited d-d transitions consistent with a distorted square-planar geometry around the Cu(II) center. Elemental analysis was consistent with the proposed molecular formula, while mass spectrometry provided 2:1 (ligand to metal ratio) coordination and the molecular weight of the complex. MALDI-TOF-MS spectra and SCXRD supported the proposed molecular composition, validating the successful synthesis of complex. Comprehensive *in silico* ADME assessments were performed to evaluate the drug-likeness and pharmacokinetic behavior of the complex [2, 3]. Studies showed that the Cu(II) complex has low gastrointestinal absorption and cannot cross the blood-brain barrier. Solubility predictions indicated moderate to poor solubility (logS values between -4.70 and -6.78). The complex is a P-gp substrate and CYP450 analysis suggests it may inhibit CYP2C9 and CYP3A4, but not the other major CYP enzymes. Drug-likeness filters showed several violations due to its high molecular weight and large TPSA. Although oral bioavailability appears limited, the complex showed no PAINS alerts and acceptable synthetic accessibility, supporting its potential for further biological studies.

Keywords: copper(II) complexes, 1,2,3-triazoles, ADME.

Abstract

In this study, the protective effects of the ethanol lyophilized extract (LBE) and nanoparticle extract (NBE) of *Eremurus spectabilis* M. Bieb. (Çiriş Herb) at different doses were evaluated in a rat model of hepatocellular carcinogenesis induced by diethylnitrosamine (DEN) and thioacetamide (TAA). To determine a safe dose for warm-blooded organisms, an acute toxicity test was performed at 2000 mg/kg. The rats were divided into six groups (n=8). Except for the Normal Control (NC), all groups received 150 mg/kg DEN (once monthly) and 200 mg/kg TAA (once weekly) intraperitoneally throughout the experiment. LBE and NBE extracts were administered daily by gavage for 90 days. Serum analyses showed that ALT and AST levels significantly increased in the Cancer Control (CC) group compared to the NC group, while these increases were largely reduced to near-normal levels in the extract-treated groups. Body-weight gain was significant in the NC, CC, and KNBE2 groups, whereas no significant increase was observed in the other groups. The oxidative stress induced by the HCC model resulted in increased CAT, GPx, GST, and SOD activities and elevated MDA levels in all experimental groups, along with decreased GR activity and GSH levels. However, in the LBE- and NBE-treated groups, free radical accumulation was suppressed; MDA, CAT, and GPx levels decreased compared to the CC group, while GR, GST, and SOD activities and GSH levels increased, indicating an enhanced antioxidant defense system. Although liver tissue 8-OHdG levels were higher in all experimental groups than in NC, histopathological examinations showed milder liver damage in the plant-treated groups. In conclusion, the extracts of *Eremurus spectabilis* M. Bieb. may exhibit protective effects against HCC due to their antioxidant and antitumor constituents.

Abstract

Nickel (Ni), a heavy metal that occurs naturally and can accumulate in aquatic environments as a result of both natural and human activities. Although Ni plays a minor but essential role in plant growth, excessive levels can have adverse effects on plants physiology through the disruption of vital biological processes and functions. *Anubias nana* Engl. (Araceae) is a popular slow-growing aquatic plant, is a promising candidate for heavy metal accumulation due to its high adaptability. This study examined the mineral nutrient profile of *A. nana* Engl. under Ni exposure and assesses its potential for sustainable heavy metal removal in aquatic ecosystems. Additionally, the genotoxic effects of Ni exposure were assessed. Genomic template stability (GTS) was calculated using ISSR markers (UBC808, UBC811, UBC834, UBC841, UBC842) with a focus on detecting the appearance or disappearance of DNA bands and variations in their intensity. Plants were cultivated in tanks containing 0.2% Hoagland solution for a period of 10 days at a temperature of 28 ± 1°C, with the objective of promoting growth and acclimatizing to the aquarium environment. Thereafter, the plants were subjected to $NiCl_2.6H_20$ stress, with concentrations of 0, 10, 25, 50, and 100 µM. Leaves, stems and roots were harvested 10 days after Ni treatment (both washed and unwashed) were analyzed using a PerkinElmer Optima 7000DV ICP-OES to determine their heavy metal and mineral nutrient contents (B, Ca, Cu, Fe, K, Mg, Mn, Na, Ni, Zn). The total chlorophyll content and phytoremediation parameters, including bioaccumulation index (BAI), bioconcentration factor (BCF), translocation factor (TF), surface adsorption (SA), surface adsorption efficiency (SAE) and removal efficiency (RE), were subsequently calculated to assess the plant's physiological responses to Ni exposure and to evaluate its phytoaccumulation potential. The findings demonstrated a concentration-dependent increase in Ni accumulation. The highest Ni accumulation, was detected in unwashed leaf samples at 100 µM, reaching 47.310 mg kg^{-1}. At the same concentration, the stem exhibited the highest BAI (16.33). The highest BCF was found in the leaf at 10 µM (3.93), while the highest TF (2.3) was recorded in the leaf/root at 10 µM. The SA reached 4.75 at 100 µM, whereas the maximum SAE was 77% at 10 µM. Additionally, the highest RE was found to be 7.95% at 100 µM. These findings indicate that *A. nana* is a capable accumulator of Ni. Genotoxicity analysis using the UBC811 primer revealed new band formation at 900 bp in both 50 µM and 100 µM treatments. Accordingly, the polymorphism rate was calculated as 3.13% and the GTS decreased to 96%. Although alterations in band intensity were observed, the overall genotoxic effects remained limited. Overall, *A. nana* demonstrated strong Ni accumulation capacity while maintaining high genomic stability, exhibiting only minor genotoxic alterations under increasing Ni stress.

A bibliometric analyse of scientific studies on the invasive species *Lepomis gibbosus*

Ufuk Gürkan Yıldırım

Isparta University of Applied Sciences, Eğirdir Fisheries Faculty, Isparta

Abstract

Lepomis gibbosus (pumpkinseed sunfish), native to North America, has spread as an invasive species across multiple continents due to anthropogenic influences and waterway connectivity. It typically inhabits vegetated lakes, ponds, and the slow-moving pools of creeks and small rivers. The species feeds on small fish, other vertebrates, and fish eggs. Adult individuals rarely form schools, usually occurring in pairs or loose groups of three to four, whereas juveniles aggregate in relatively large schools. Introduced to Europe, *L. gibbosus* avoids fast-flowing waters and can also be found in estuarine environments with salinity levels up to 18.2 ppt. It has been reported to prey on a wide variety of mollusks and other invertebrates in Europe. From a fisheries perspective, it is considered an undesirable catch. This study presents a comprehensive bibliometric analysis aimed at revealing the global development of scientific research on the invasive freshwater fish *Lepomis gibbosus*. A total of 774 academic publications indexed in the Web of Science database were evaluated in terms of scientific productivity, citation performance, international collaboration networks, and thematic research trends. Bibliometric analyses were conducted using raw data from the Web of Science with the aid of the R programming language and VOSviewer software. The study examined the distribution of publications over time, the most influential authors and journals, geographic publication density, and keyword co-occurrence networks in detail. Findings indicate a marked increase in research on *L. gibbosus* since the early 2000s, with publication output predominantly concentrated in European countries. The literature highlights key research themes such as the species' ecological impacts, invasion dynamics, habitat utilization, and competitive pressures on native fish communities. Additionally, the invasive range of *L. gibbosus* is rapidly expanding across Europe, attributed to its high environmental tolerance, reproductive success, and anthropogenic dispersal via aquatic systems. In conclusion, this study provides a holistic overview of the structural characteristics of scientific production on *L. gibbosus* and offers significant insights for the ecological management of the species as well as future research priorities.

Corresponding author e-mail: skavlak@hacettepe.edu.tr

Abstract

In this work, a series of novel functional copolymer/layered silicate nanocomposites were synthesized by *in situ* radical-initiated copolymerization in solution. The interaction of the organic units with clay and the structural analysis of the synthesized poly(AAm-*co*-CA)/organo-MMT nanocomposites were elucidated by ^{1}H NMR and ATR-FTIR spectroscopy. Characteristic peaks belong to the functional groups of the synthesized copolymer units and organo-MMT were identified in the spectra of the nanocomposites. Structures of the synthesized nanocomposites and the effect of the organically modified montmorillonite clay on the structural properties were investigated by complementary XRD analyses. Intercalation of comonomers in between silicate layers of organically modified montmorillonite was clarified by the increase in *d*-spacing in nanocomposites between 3.80% and 51.60%.[1] The obtained results confirmed the *in situ* interlamellar synthesis of the nanocomposites by intercalation of comonomers into the organically modified montmorillonite layers and showed that nanocomposites with intercalated structure were successfully obtained. These results will contribute to the design and synthesis of functional nanomaterials that may offer different applications.

Keywords: functional copolymer, clay, nanocomposite

Özet

Alkali ve tuzlu toprak koşulları, bitkilerde besin elementlerinin biyoyararlılığını önemli ölçüde azaltarak büyüme geriliği, pigment kaybı ve oksidatif stres gibi çeşitli fizyolojik bozukluklara yol açmaktadır. Bu koşullarda alımı en fazla kısıtlanan mikro elementlerden biri olan demir (Fe), özellikle kloroz, fotosentetik kapasite azalması ve verim düşüklüğüyle ilişkilidir. Bu çalışma, yerel kaynaklardan geliştirilen EDDHA-Fe şelat kompleksinin, yüksek pH ve tuzluluk altında yetiştirilen salatalık (*Cucumis sativus* L.) bitkisinin morfolojik ve fizyolojik yanıtları üzerindeki etkilerini belirlemeyi amaçlamaktadır.
Denemede, yerli EDDHA-Fe formülasyonu, iki ticari demir şelatı (Sequestrene ve Tariron) ile karşılaştırmalı olarak uygulanarak analizler gerçekleştirilmiştir. Uygulamalar sonrasında bitkilerde lipid peroksidasyonu (TBARS), hidrojen peroksit (H_2O_2), toplam klorofil ile taze ve kuru ağırlık ölçümleri gerçekleştirilmiş; ayrıca yapraklarda DAB boyama ile H_2O_2 birikimi ve çiçeklenme–meyve oluşumu gibi morfolojik göstergeler değerlendirilmiştir.

Elde edilen bulgular, yerli EDDHA-Fe uygulamasının hem kontrol hem de tuz stres koşullarında bitki gelişimini anlamlı düzeyde desteklediğini ortaya koymuştur. Özellikle klorofil içeriği, taze ağırlık ve çiçeklenme gibi büyüme parametreleri açısından yerli formülasyonun güçlü ve istikrarlı bir performans sergilediği belirlenmiştir. Oksidatif stres göstergeleri olan TBARS ve H_2O_2 seviyelerinin düşmesi, yerli formülasyonun stres koşullarında hücresel hasarı azalttığını göstermiş; DAB boyama sonuçları bu etkiyi dokusal düzeyde doğrulamıştır.
Sonuçlar, yerli kaynaklı EDDHA-Fe şelat kompleksinin ticari muadilleriyle karşılaştırıldığında benzer veya daha üstün etki gösterebildiğini, ayrıca çevre dostu ve sürdürülebilir bir gübre alternatifi olma potansiyeline sahip olduğunu göstermektedir.

Anahtar Kelimeler: Demir şelatı, EDDHA, Tuzluluk, Yüksek pH, Demir eksikliği, Oksidatif stres, Sürdürülebilir gübre

Abstract

Surfactants are a large group of chemicals widely used in industry, in cleaning and sterilization processes, in pharmaceuticals, in personal care and cosmetic products, etc. Given their extensive consumption and high toxicity, the monitoring of surfactants is extremely important for industrial processes and quality and environmental control. In this study, polymeric membrane cationic surfactant-selective glassy carbon electrodes (CSGCEs) were prepared, utilizing certain Schiff bases as ionophores, for the potentiometric determination of didecyldimethylammonium chloride (DDMACl), which is a cationic surfactant. The electrode performance was studied by changing the type and quantity of the ionophore and plasticizer within the polyvinyl chloride (PVC)-based polymeric membranes. Additionally, the influence of certain nanomaterials and a lipophilic additive included in the composition was also assessed. The glassy carbon electrode with a membrane composition consisting of 1 mg each of N-salicylidene-2-aminophenol (ionophore), sodium tetraphenylborate (lipophilic additive), chitosan (nanomaterial), TiO_2-NP (nanoparticle), 66 mg tributyl phosphate (plasticizer) and 30 mg PVC, was observed to exhibit the best performance in DDMACl sensitivity. It was determined that the DDMACl-selective electrode gave a linear response in the concentration range of 1.0×10^{-3}-1.0×10^{-6} M with a slope of -58.6±3.0 mV/pDDMACl at pH 4.0 and the detection limit was 2.5×10^{-7} M. The response time of the electrode was 5-8 s. The behavior of the proposed electrode in the presence of some interference species was investigated by determining the selectivity coefficients calculated with the fixed interference method (FIM). Various disinfection products obtained from markets were used for analytical application.

Keywords: Surfactant determination, potentiometry, ion-selective electrode, lipophilic additive, nanomaterial.

Abstract

Azospiro-based frameworks have recently emerged as valuable structures in pharmaceutical research. Nitrogen containing spiro-heterocycles represent a key synthetic scaffold present in numerous natural products and are associated with diverse biological and pharmacological activities. Ongoing studies continue to highlight the importance of designing new molecules within this class and evaluating their biological profiles including fungicidal, herbicidal, antibacterial and antimicrobial properties. In addition, the well-documented bioactivity of barbituric acid derivatives has further stimulated interest in the development of 2,4-diazaspiro [5.5] undecane derivatives. Microwave assisted organic synthesis has garnered significant interest owing to its capacity to enhance reaction efficiency, increase product yields, and shorten reaction times. In this study, we performed the microwave reaction between N,N-dimethyl barbituric acid and penta-1,4-diene-3-one derivatives ((1E,4E)-1,5-bis(5-methylfuran-2-yl)penta-1,4-dien-3-one and (1E,4E)-1,5-bis(2-methoxyphenyl)penta-1,4-dien-3-one). At a result of these reactions, we obtained 2,4-Dimethyl-7,11-bis(5-methylfuran-2-yl)-2,4-diazaspiro [5.5] undecane-1,3,5,9-tetraone and 7,11-Bis(2-methoxyphenyl)-2,4-dimethyl-2,4-diazaspiro [5.5] undecane-1,3,5,9-tetraone. The reaction was performed under microwave irradiation providing a more environmentally benign and energy-efficient process. Key parameters including reaction time, temperature and microwave power were systematically optimized to achieve the highest possible yield. The resulting compound was subsequently characterized using a range of spectroscopic techniques such as IR, ^{1}H-NMR, ^{13}C-NMR, and mass spectrometry (MS). These compounds possess noteworthy pharmacological properties and represent promising scaffolds for the development of new therapeutic agents. Their anticancer activity was evaluated using the SK-HEP-1 adenocarcinoma cell line and the results demonstrated significant inhibitory effects on liver adenocarcinoma cells. This study contributes to assessing the therapeutic potential of these molecules and further supports the relevance of microwave assisted synthesis in early-stage drug discovery.

Özet

Yaşam süresince maruz kalınan; hava-su kirliliği, hazır yiyecekler, stres gibi çeşitli etkenlerin insan sağlığı üzerine olumsuz etkileri bulunmakta ve bu etkenler sonucunda serbest radikaller oluşmaktadır. Antioksidanlar, meydana gelen bu durumda devreye girerek, yükseltgenebilen maddeler olduklarından, radikal zincir tepkimesini kesintiye uğratıcı rol oynamaktadırlar. Kaliteli beslenme yardımı ile yüksek biyoaktiviteye sahip toplam fenolik madde miktarı bol gıdalar ve bağışıklık sistemini güçlendirecek takviye edici gıdaların diyete dahil edilmesi, kardiyovasküler hastalıklar, kanser, obezite ve nörolojik bozukluklar dahil olmak üzere birçok kronik hastalığın görülme sıklığını azaltmakta ya da başlangıcını geciktirmektedir. Yüksek biyoaktiviteye sahip gıdalardaki fenolik bileşikler belirlenerek, bunların gıda sistemlerindeki etkilerinin incelenmesi ile gıda içeriğine yönelik üretim ve denetim devamlılığının sağlanması büyük önem taşımaktadır[1]. Bu nedenle fenolik bileşiklerin düşük derişimlerde dahi hızlı ve duyarlı bir şekilde tayin edilmesi önem arz etmektedir. Polifenol oksidaz (PFO) enziminin kullanıldığı enzim biyosensörleri; düşük maliyetli, hızlı, pratik, yüksek hassasiyette ve düşük tayin limiti olanağı sağladığı için, fenolik bileşenlerin tayin edilmesinde diğer metotlara göre iyi bir alternatiftirler[2,3]. Bu çalışmada, Ananasın (*Ananas comosus* (L.) Merr.) atık niteliğindeki taç yapraklarından sentezlenen gümüş nanopartiküller (AgNPs) modifiye karbon pasta elektrot (MCPE) tasarımında kullanıldı. Fenolik madde miktarı tayini için, *Bacillus subtilis* bakterisinden izole edilerek saflaştırılan PFO enzimi, MCPE yüzeyine glutaraldehit ile çapraz bağlanarak immobilize edildi. Enzimatik tepkime sonucu oluşan *o*-kinon bileşiğinin oluşturduğu katodik (indirgenme) akımın ölçülmesiyle de fenolik bileşiklere duyarlı elektrokimyasal esaslı bir biyosensör sistemi geliştirildi. Tasarlanan biyosensörün amperometrik cevabına; pH, sıcaklık ve substrat derişimi etkisi gibi çalışma koşulları belirlendi. Optimum çalışma koşulları; *-0,15 V* çalışma potansiyeli, modifiye etmek için *20 mg* AgNPs miktarı olarak belirlendi. Biyosensörün doğrusal çalışma aralığı, alt tayin sınırı değerleri tespit edildi ve $Km_{(göz)}$ 0,002 µM, $Imax_{(göz)}$ 1,00 µA olarak hesaplandı. Biyosensörün performansını etkileyen tekrarlanabilirlik ve depolama kararlılığı etkisi incelendi. Substrat olarak kullanılan katekol tayinine, girişim yapabilecek türlerin etkileri incelendikten sonra PFO temelli biyosensör, takviye edici gıda örneklerinde fenolik madde miktarı tayininde kullanıldı.

Anahtar Kelimeler: Fenolik bileşik, biyosensör, polifenol oksidaz, karbon pasta elektrot, takviye edici gıda

[2] Bilecik Şeyh Edebali Üniversitesi, Biyoteknoloji Araştırma ve Uygulama Merkezi, Bilecik, Türkiye

Özet

Kemoterapi ve radyoterapi gibi kanser tedavisinde kullanılan bilimsel tedavilerin normal hücrelere verdiği zararlar ve bireyler üzerindeki yan etkileri nedeniyle, bitkisel veya diğer doğal kaynaklı ajanların bilimsel tedavilere ek olarak kullanımına ilişkin araştırmalar devam etmektedir. Bir polifenol olan resveratrol antep fıstığı, yaban mersini ve üzüm gibi yaygın gıdalarda bulunur. Çok sayıda çalışma, resveratrolün güçlü anti-inflamatuar, antioksidan ve antikanser aktivitelere sahip olduğunu göstermiştir. Bu çalışmada Resveratrol'ün 4T1 meme kanseri hücre hattı üzerindeki sitotoksik etkisi araştırılmıştır. Resveratrol'ün 4T1 meme kanseri hücre hattında konsantrasyona bağlı hücre canlılığı üzerindeki etkisini araştırmak için MTT testi, apoptoz üzerindeki etkisi belirlenmek için bir Caspase 3/7 apoptoz kiti kullanıldı. BAX/BCL-2 genlerinin ifade seviyeleri Real-time PCR ile belirlendi. MTT sonuçlarına göre, Resveratrol'ün 4T1 meme kanseri hücre hattı üzerindeki 24 saatlik IC50 değeri 70 µM, 48 saatlik IC50 değeri ise 30 µM olarak bulundu. İlaç hücrelere uygulandığında, hücre sayısında azalma, hücre boyutunda küçülme ve hücre uzantıların kaybolarak yuvarlak bir şekil aldığı gözlemlendi. Resveratrol ile tedavi edilen hücre grubunun Cas3-7 aktivite seviyeleri kontrol grubu ile karşılaştırıldı. BAX ve BCL-2 genlerinin ekspresyon seviyeleri kontrol ile karşılaştırıldı. Resveratrol tedavisinin 4T1 meme kanseri hücre canlılığını doza ve zamana bağlı olarak önemli ölçüde azalttığı gözlemlenmiştir.

Anahtar Kelimeler: Resveratrol, 4T1, Meme kanseri, Sitotoksik Etki

Abstract

Endometrial cancer is an epithelial malignancy originating from the endometrium, the inner lining of the uterus, and is one of the most common gynecological cancers in women. Chronic inflammation has been identified as playing an important role in cancer development and progression. TLR2 (Toll-like receptor 2) is expressed in both immune cells and tumor cells and occupies a critical intersection between chronic inflammation and cancer. TLR2 activation can stimulate pro-tumor pathways such as NF-κB, PI3K/AKT, and ERK1/2, which can increase cell proliferation, inhibit apoptosis, and create an inflammatory environment in the tumor microenvironment. Furthermore, TLR2 expression has been reported to be significantly higher in endometrial cancer samples compared to control groups. Based on this information, we investigated the association of two TLR2 polymorphisms, rs5743708 and rs121917864, with endometrial cancer risk in our study. The PCR-RFLP method was used to determine the variants. As a result of our study, a significant difference was observed in the genotype frequencies of the TLR2-rs121917864 polymorphism between patients and control subjects ($p<0.05$), while no significant difference was observed in terms of allele frequency. For the TLR2-rs5743708 variant, both genotype and allele frequencies were found to be significantly different between patients and control subjects ($p<0.0001$). The findings obtained in light of these results support the potential roles of inflammatory pathways and immune receptors in endometrial carcinogenesis.

Abstract

The extracellular matrix (ECM) is a dynamic three-dimensional structure surrounding cells in tissues, composed of structural and specialized proteins (collagen, elastin, fibronectin, laminin), proteoglycans and glycosaminoglycans, and ECM-associated enzymes, which is essential for cellular homeostasis, migration, and proliferation. Matrilins are ECM proteins that interact with collagen-associated fibrils, aggrecan, COMP, and various collagen types. MATN3 is one of four members of the Matrilins (MATN1, MATN2, MATN3, and MATN4). Matrilins are involved in various cancers, such as cervical cancer, melanoma, and hepatocellular carcinoma. While the oncogenic role of MATN3 in gastric cancer is established, its impact on osteosarcoma has only been explored through bioinformatics studies. Osteosarcoma is a high-grade bone tumor originating from mesenchymal cells, distinguished by the formation of malignant osteoid or immature bone matrix, with low survival rates for metastatic or recurrent cases. Current bioinformatics studies aim to identify genes influencing osteosarcoma prognosis and metastasis. Epithelial-Mesenchymal Transition (EMT) is a key process in cancer metastasis, enabling tumor cells to acquire invasive properties. A recent bioinformatics analysis suggested that the MATN3 gene may play a role in osteosarcoma (OS) metastasis and is linked to EMT regulation. The study further found that MATN3 expression was significantly lower in metastatic OS tissue compared to primary tumors. In this study, we aimed to elucidate the potential role of MATN3 on OS proliferation. Therefore, MATN3 was knocked down in osteosarcoma (OS) cell lines using a siRNA approach with specific siRNAs, confirming silencing via Western Blot. The proliferation and migration properties of osteosarcoma cells with silenced *MATN3* gene were determined by functional assays (MTT, wound healing, and transwell). The results would contribute to the understanding of the functional role of MATN3 on OS proliferation.

Abstract

Cancer is a multistep process in which genomic instability and disruption of epigenetic regulation occur simultaneously. Many of these molecular alterations are mediated by the ubiquitin–proteasome system (UPS), which modulates protein stability, chromatin dynamics, and transcriptional programs. UHRF2 is a critical E3 ubiquitin ligase within the UPS, and is a nuclear regulator that exerts substrate-specific ubiquitin ligase activity. UHRF2 plays a role in regulating DNA methylation, histone modifications, and cell cycle control. UHRF2 has shown that it contributes to tumor progression in colon and breast cancers, but exhibits tumor-suppressive functions in leukemia and non-small cell lung cancer. Bioinformatic analyses in osteosarcoma have indicated that UHRF2 is overexpressed in osteosarcoma tissues compared to normal bone and appears among ubiquitin-related genes associated with a poor prognosis, implying a potential oncogenic function. Osteosarcoma is an aggressive primary bone sarcoma of children and adolescents, characterized by immature osteoid formation, high proliferative capacity, and early metastatic behavior. Herein, we aimed to elucidate the contribution of the UHRF2 to osteosarcoma proliferation and migration. In this context, UHRF2 expression was determined at both the mRNA (qRT-PCR) and protein (western blot) levels in osteosarcoma cell lines. The *UHRF2* gene was silenced using siRNAs in 143B cells, where it was highly expressed, and the silencing efficiency was confirmed by Western blot. The knockdown of UHRF2 on cell proliferation and metastasis was evaluated using MTT, wound healing, transwell, and colony formation assays. To determine its effect on the EMT (Epithelial-Mesenchymal Transition), specific biomarkers were analyzed by Western blot. The results would provide insight into determining the functional role of UHRF2 in osteosarcoma and its potential as a therapeutic target.

Özet

Kompozit malzemeler, polimer bir matris içine farklı boyutlardaki takviye fazlarının homojen şekilde dağıtılmasıyla elde edilen ve geleneksel malzemelere göre daha üstün performans sergileyen gelişmiş yapılardır. Takviye fazlarının geniş yüzey etkileşimi sayesinde matris ile güçlü bağlar oluşur ve bu sayede nispeten düşük dolgu oranlarında bile mekanik dayanım, termal kararlılık, optik özellikler ve bariyer performansında belirgin iyileşmeler sağlanır. Özellikle selüloz esaslı yapılar; yenilenebilir kaynaklı olmaları, hafiflikleri, biyouyumlulukları ve fonksiyonlandırılabilir olmaları sayesinde sürdürülebilir kompozit tasarımlarında önemli avantaj sunar. Bu tür kompozitler; kaplamalardan paketlemeye, biyomedikal malzemelerden yapısal uygulamalara kadar geniş bir kullanım alanına sahip olup, takviye fazının matrise kazandırdığı çok yönlü özelliklerle yüksek performanslı malzeme geliştirme çalışmalarında temel bir rol oynamaktadır. Bu çalışmada, selüloz yüzeylerindeki hidroksil gruplarına tersiyer amin fonksiyonları eklenmiş ve bu fonksiyonel yapıların II. tip fotopolimerizasyon yaklaşımıyla mikroselüloz takviyeli kompozitlerin hazırlanmasında kullanılması sağlanmıştır. Fotopolimerizasyon sonucu monomerlerin selüloz yüzeyine kimyasal olarak bağlanmasıyla elde edilen kompozitler, dolgu içermeyen saf polimere kıyasla daha yüksek termal ve mekanik performans sergilemiştir. Hazırlanan, farklı oranlarda mikroselüloz içeren kompozitlerin termal, morfolojik ve mekanik özellikleri saf polimer ile karşılaştırmalı olarak değerlendirilmiş ve optimum dolgu oranı belirlenmiştir. Mekanik özellikler incelendiğinde, en iyi performansın %5 MS takviyesiyle elde edildiği görülmüştür. Bu dolgu oranında çekme dayanımı belirgin şekilde artmış, uzama değerlerinin de iyileşmesiyle daha güçlü ve aynı zamanda daha elastik bir yapı oluşmuştur. Bu nedenle, saf termoset ile kıyaslandığında %5 MS takviyesi en uygun ve en başarılı dolgu seviyesi olarak değerlendirilmektedir.

Anahtar Kelimeler: Mikrokompozit, selüloz, II. Tip fotopolimerizasyon

Atık kahve telvesinden türetilen mezogözenekli karbon katkılı PVDF Bazlı PEM yakıt pili membranlarının geliştirilmesi

Minel Mil[1]*, Ceren Karagözlü[1], Yavuz Yağızatlı[1]

*[1]Gazi Üniversitesi, Mühendislik Fakültesi, Kimya Mühendisliği Bölümü, Ankara, Türkiye

*Sorumlu yazar e-mail: milminelll@gmail.com

Özet

Bu çalışmada, atık kahve telvesinden H_3PO_4 aktivasyonu ile 500 °C'de azot atmosferinde karbonize edilerek elde edilen aktif karbonun PEM yakıt pilleri için katkı malzemesi olarak kullanılabilirliği incelenmiş ve bu karbon PVDF bazlı kompozit membranların sentezinde kullanılmıştır. Aktif karbonun FTIR analizinde O–H ve C–H gerilme bantlarının büyük ölçüde kaybolması aromatik karbon iskeletinin oluştuğunu, 1000–1100 cm^{-1} bölgesindeki C–O piklerinin güçlenmesi ise kimyasal aktivasyonun etkinliğini göstermiştir. XRD analizlerinde gözlemlenen geniş ve düşük şiddetli pikler, karbonun amorf fakat düzenli bir yapıya sahip olduğunu ortaya koymuştur. Sentezlenen aktif karbon PVDF matrisine %1, %5 ve %10 oranlarında eklenmiş ve elde edilen membranlar su tutma kapasitesi, şişme davranışı, boyutsal kararlılık, proton iletkenliği, iyon değişim kapasitesi, mekanik dayanım ve yapısal analizlerle değerlendirilmiştir. Su tutma kapasitesi en yüksek %5 katkıda gözlemlenirken, şişme testleri karbon katkısının membran kararlılığını artırdığını göstermiştir. Proton iletkenliği açısından %10 karbon katkılı membran 1,9931 mS/cm ile en yüksek performansı sergilemiş; aynı katkı oranında iyon değişim kapasitesi de 2,26 meq/g ile maksimuma ulaşmıştır. Mekanik dayanım %1 katkıda en yüksek seviyeye ulaşmış, ancak %10 katkıda topaklanma nedeniyle bir miktar düşüş görülmüştür. FTIR ve XRD sonuçları, karbon katkısının PVDF'nin kristal yapısını bozarak daha amorf ve proton iletimini destekleyen bir yapı oluşturduğunu ortaya koyarken, yüksek katkı oranlarında yüzeyde aglomerasyonun arttığı belirlenmiştir. Genel olarak, kahve telvesinden elde edilen aktif karbonun yapısal ve fonksiyonel özellikleri, özellikle %10 katkılı PVDF membranın PEMFC uygulamaları için en yüksek verimliliği sunduğunu göstermektedir.

Anahtar Kelimeler: Atık Kahve Telvesi, Aktif Karbon, PVDF Membran, PEM Yakıt Pili, Proton İletkenliği.

Abstract

Trigonella coerulescens (M.Bieb.) Halácsy subsp. *ayvalikensis* Erdoğan, Selvi & Tümen (Fabaceae) is an endemic species known from only two localities in Balıkesir-Ayvalık from Türkiye. This taxon was described in 2017, and the IUCN threat category was recommended "Vulnerable (VU)" by the authors of the species. It grows in sandy soils in the coastal areas of Ayvalık and blooms in March-May. With this study, the species has a new distribution area in Görenez Mountain, Akhisar-Manisa. It was distributed above the tree line at about 1200 m altitude on the western view of Görenez Mountain. The flowering time of the population in Görenez Mountain is May. Based on the observations made during the field study, it was concluded that the species should be protected in the same IUCN threat category.

Abstract

The red-emitting phosphor CASN:Eu^{2+} (CASN) is widely used in display and lighting technologies. This study investigated the photoluminescence properties of CASN together with the highly fluorescent green-emitting Pyranine (Py) dye embedded in a polymeric (polymethyl methacrylate, PMMA) matrix. Binary and ternary phosphor–dye blends were prepared with and without an ionic liquid (IL). All composites were fabricated in film form, and excitation-emission and decay-time measurements were taken from these films. Upon blue-light excitation, the IL-free binary CASN–Py composite exhibited an 18 nm red shift and a 38% increase in emission intensity compared to the phosphor alone, while the IL-doped ternary composite showed a 400% enhancement in emission intensity. The decay time measurements were performed on the nanosecond scale, revealing changes consistent with the observed increases in emission intensity. These results highlight the promising potential of IL-doped CASN:Eu^{2+}–Pyranine composites for WLED, OLED, and display applications.

Abstract

The demand for sustainable and functional plant-based protein sources in the food industry is steadily increasing. Hazelnut press cake, a by-product of oil production, contains a high amount of protein but remains underutilized. Conventional alkaline extraction methods provide high protein yields; however, they often cause protein denaturation, negatively affecting critical functional properties such as solubility, emulsification, and foaming, while also generating considerable chemical waste. Therefore, greener extraction strategies that preserve protein structural integrity are urgently needed. This study aims to develop an environmentally friendly protein extraction method using Deep Eutectic Solvents (DES) to improve protein recovery from hazelnut press cake and to obtain protein isolates with preserved structural and functional properties suitable for food applications. Three DES systems (ChCl–glycerol, ChCl–sorbitol, and ChCl–glucose) were synthesized and applied in ultrasound-assisted extraction. The resulting protein isolates were compared with those obtained through conventional alkaline extraction at pH 8, 9, and 10. All extracts were comprehensively evaluated in terms of protein yield, solubility, emulsifying and foaming properties, particle size, zeta potential, as well as FTIR, SDS-PAGE, intrinsic fluorescence emission, and SEM analyses. Results showed that alkaline extraction at pH 10 achieved the highest protein yield (~260 mg/g), whereas DES systems offered superior solubility (70–76%) and enhanced emulsifying performance. Among DES systems, DES–glycerol exhibited the highest emulsifying activity, while DES–sorbitol demonstrated the greatest emulsion stability. In contrast, foaming capacity was higher in alkaline-extracted samples. Structural analyses indicated that DES-extracted proteins underwent less denaturation and retained more native characteristics. Overall, this study demonstrates that hazelnut press cake can be valorized as an environmentally friendly and functionally superior plant protein source through DES-assisted extraction, offering a promising alternative for sustainable food production.

Keywords: hazelnut meal, protein extraction, deep eutectic solvents, functional properties, emulsion stability.

Abstract

The unique structural adaptability of shark-derived single-domain antibodies (VNARs) presents a promising platform for therapeutic development; however, the dynamic consequences of stabilizing mutations remain inadequately characterized. This study employs a comprehensive computational framework to elucidate how targeted mutations alter the conformational landscape of a model VNAR in its apo and lysozyme-bound states. We generated conformational ensembles for the wild-type and 13-mutant variant using the unbiased ClustENMD sampling method, which integrates elastic network model, clustering, and molecular dynamics simulations. These ensembles were analyzed via Principal Component Analysis (PCA) to map dominant motions, revealing that the mutant exhibits constrained global flexibility compared to the wild-type. To classify state-specific conformations and identify critical residue-level discriminators, we applied Linear Discriminant Analysis (LDA) and Random Forest algorithms. These analyses pinpointed several residues in the hypervariable (HV2, HV4), complementarity determining (CDR1, CDR3), and framework (FW3) regions as key differentiators, suggesting long-range allosteric effects. Centrality analysis of residue interaction networks further quantified mutation-induced perturbations in allosteric communication, identifying central residues that overlapped with LDA findings. Finally, Essential Site Scanning Analysis (ESSA) corroborated the significance of the HV4, FW3, and CDR3 regions. Our integrated approach demonstrates that the mutations predominantly perturb dynamics in regions critical for antigen binding and structural integrity. Notably, our findings underscore the FW3 region as a potential allosteric hotspot. These findings not only decipher mutation-induced dynamical shifts but also provide a blueprint for the rational design of stabilized VNARs with enhanced therapeutic properties.

Sorumlu yazar e-mail:ozgetokul@gmail.com

Özet

Sarımsak (*Allium sativum* L.), organosülfür ve fenolik bileşikleri sayesinde antioksidan, antimikrobiyal, antihipertansif ve kardiyovasküler açıdan destekleyici etkilere sahip önemli bir fonksiyonel gıdadır [1]. Son yıllarda yapılan araştırmalar, genellikle tarımsal atık olarak değerlendirilen sarımsak kabuklarının da fenolik bileşikler bakımından zengin bir içerik sunduğunu ve dikkate değer biyolojik aktivitelere sahip olabileceğini göstermektedir. Lignoselülozik yapısı nedeniyle doğal bir polifenol kaynağı olarak değerlendirilen sarımsak kabuğu, hem gıda endüstrisinde doğal katkı maddesi hem de sürdürülebilir biyoaktif bileşen üretimi açısından potansiyel bir hammadde niteliği taşımaktadır [2]. Bu çalışmada, altı farklı coğrafi bölgeden temin edilen 13 sarımsak örneğinin kabuk ve yenilebilir kısımları ayrı olarak incelenerek kimyasal profillerindeki farklılıklar araştırıldı. Etanol ile ekstre edilen örneklerin, FTIR spektroskopisi kullanılarak yapısal parmak izleri belirlendi. 2D-Korelasyon Spektroskopisi (2D-COS) ile spektral bantlar arasındaki ilişkiler değerlendirildi. Fenolik içerik HPLC-DAD ile analiz edildi ve FTIR verileri ise temel bileşen analizi (PCA) kullanılarak sınıflandırıldı. HPLC-DAD sonuçları, kabuk ve yenilebilir kısımlar arasında belirgin bir fenolik çeşitlilik farkı olduğunu gösterdi. Yenilebilir kısımlarda sadece fumarik asit, gallik asit, protokateşuik asit ve 2,4-dihidroksibenzoik asit tespit edilirken, kabuk ekstrelerinde toplam 15 farklı fenolik bileşik belirlendi. Bunlar arasında krisin, hesperidin, ferulik asit ve kafeik asit gibi bileşikler daha yüksek yoğunlukta gözlendi. FTIR–2D-COS analizleri, kabuk ve yenilebilir kısımlar arasında özellikle 3600–3000 cm^{-1} (O–H gerilme titreşimleri), 1700–1500 cm^{-1} (C=O gerilme titreşimleri) ve 1200–900 cm^{-1} (organik ve sülfür bileşenlerine ait titreşimler) bölgelerinde anlamlı spektral farklılıklar ortaya koydu. PCA sonuçları, FTIR ve 2D-COS verileri birlikte değerlendirildiğinde, sarımsak ve kabuklarının coğrafi farklılıklarının belirlenmesinde doğruluğu yüksek bir yaklaşım sunmaktadır. Sonuç olarak, bu çalışma sarımsak kabuklarının fenolik bileşikler açısından yenilebilir kısımlara kıyasla daha geniş bir çeşitlilik gösterdiğini ve FTIR–2D-COS ile PCA'nın sarımsak ve kabuklarının kimyasal parmak izinin değerlendirilmesinde etkili yöntemler olabileceğini ortaya koymaktadır. Bu çoklu analiz yaklaşımı yöntemlerini HPLC-DAD analizleri desteklemektedir.

Anahtar Kelimeler: Sarımsak (*Allium sativum*), FTIR–2D-COS, Temel Bileşen Analizi (PCA), HPLC-DAD, Fenolik bileşikler

Abstract

Thiamethoxam is a neonicotinoid insecticide used in agricultural practices, and its residues have been detected in surface waters worldwide. This raises concerns about its potential toxic effects on aquatic invertebrates. The present study investigated the histological alterations induced by thiamethoxam in the digestive gland and kidney of the freshwater snail *Lymnaea stagnalis*. Laboratory-cultured adult snails were exposed to environmentally relevant concentrations of thiamethoxam (0, 2, 20, and 200 µg/L) for 28 days. Exposure resulted in marked vacuolization and cellular degeneration in the digestive gland, accompanied by increased connective tissue fibers, hypertrophic hemocytes in the intertubular area, epithelial hyperplasia of the digestive tubules, necrotic cells, and disruption of overall tissue architecture. Kidney tissues of exposed specimens exhibited degenerative nephrocytes, increased hemocyte clusters between renal tubules, disrupted excretory granules, nuclear alterations, and necrosis. These findings demonstrate that chronic thiamethoxam exposure induces substantial histopathological damage in vital organs of freshwater gastropods, highlighting potential ecological risks associated with the presence of this insecticide in aquatic environments.

Keywords: Neonicotinoid, insecticide, gastropoda, histopathology, toxicity.

Abstract

CRISPR-Cas technology has emerged as an innovative molecular diagnostic platform in food microbiology, enabling rapid, specific, and highly sensitive detection of foodborne pathogens. Defined as the adaptive immune system of bacteria, CRISPR consists of palindromic repeat sequences accompanied by Cas proteins, naturally facilitating the recognition and cleavage of foreign genetic material. This mechanism has been repurposed by researchers to selectively recognize and process target DNA or RNA sequences, making it applicable to diagnostics, quality control, and biosensor applications. In CRISPR-Cas-based systems, guide RNA (crRNA or gRNA) confers target nucleic acid recognition to the Cas protein, directing specific binding and cleavage reactions. Different effector proteins such as Cas9, Cas12, and Cas13 provide diversity in structure and target type (DNA/RNA) and can be integrated with fluorescence, colorimetric, or isothermal amplification-based readout methods to create versatile diagnostic platforms. This technology offers significant advantages for on-site applications due to its rapid results, high specificity, and minimal equipment requirements, particularly in detecting foodborne pathogens and monitoring contamination. However, the complex nature of food matrices may affect nucleic acid isolation efficiency and Cas protein activity. Protocol optimization, method standardization, and minimizing off-target activities are critical challenges for routine implementation of this technology. In this study, the current applications, advantages, and limitations of CRISPR-Cas systems in pathogen detection, quality control, and rapid diagnostics within food microbiology are discussed, with a comprehensive assessment of their field adaptability and future potential.

Abstract

There is a delicate balance between cellular defense systems and reactive oxygen/nitrogen species (ROS/RNS). When this balance shifts in favor of ROS/RNS, oxidative stress occurs, resulting in damage to biological macromolecules and contributing to the development of various diseases, including cardiovascular disorders and cancer. Antioxidants, which counteract these harmful effects, play a central role in cellular defense mechanisms. Therefore, the determination of antioxidants in foods has become increasingly important, leading to the development of numerous analytical methods. In recent years, green extraction techniques such as homogenizer-assisted extraction (HAE), microwave-assisted extraction (MAE), and ultrasound-assisted extraction (UAE) have gained prominence alongside traditional antioxidant extraction methods. Optimization of operational parameters in these techniques can significantly enhance extraction efficiency. Additionally, in line with the principles of green chemistry, research on the valorization of food waste and the extraction of bioactive compounds such as antioxidants from these by-products has intensified. The discovery and application of environmentally friendly natural deep eutectic solvents (NADESs) have further accelerated the adoption of green extraction strategies. NADESs offer sustainable alternatives to conventional solvents, providing advantages such as biocompatibility, low toxicity, environmental safety, and notably high solvent power. Extracts obtained using NADESs have become widely utilized both in the development of novel functional food products and in antioxidant analyses.

Abstract

The increasing presence of synthetic dyes in industrial wastewater represents a major environmental challenge, particularly for persistent azo dyes such as Reactive Orange 16 (RO16). Developing efficient and sustainable materials capable of degrading these contaminants under solar irradiation is essential for advancing water purification technologies. Metal–organic frameworks (MOFs), with their tunable porosity, large surface area, and chemical versatility, have emerged as attractive photocatalysts1. Among them, IRMOF-3 offers enhanced visible-light absorption and adjustable surface properties due to its $–NH_2$ groups, making it a promising candidate for solar-driven photocatalytic applications2. In this study, the photocatalytic degradation of RO16 was investigated using IRMOF-3 under simulated solar light. IRMOF-3 was synthesized via a solvothermal method and characterized by X-ray diffraction (XRD), scanning electron microscopy (SEM), and Fourier-transform infrared spectroscopy (FTIR) to verify its crystallinity, morphology, and functional groups. UV–Vis spectrophotometry was used to monitor the degradation of RO16, revealing that the dye was efficiently decomposed under solar irradiation. Key experimental variables, including catalyst dosage, pH, and initial dye concentration, were systematically optimized to maximize the photocatalytic performance. Reusability tests demonstrated that IRMOF-3 retained its structural integrity and catalytic activity over multiple cycles, highlighting its stability under photocatalytic conditions. Mechanistic investigations using radical scavengers confirmed that superoxide radicals ($O_2^{\cdot -}$) were the dominant reactive species responsible for RO16 degradation.
Overall, the findings indicate that IRMOF-3 is an effective and reusable photocatalyst for the solar-driven degradation of Reactive Orange 16, offering an environmentally friendly approach for treating dye-contaminated wastewater and contributing to sustainable water purification solutions.

Keywords: IRMOF-3, Photocatalysis, Reactive Orange 16, Dye degradation, Visible-light activity, Solar-driven oxidation.

Abstract

Covid-19 pandemic is an important international public health problem. A range of susceptibility genes and genetic variants has been associated with the elevated risk of severe Covid-19 development. Among these, the Methylenetetrahydrofolate Reductase (MTHFR) gene, which encodes 5,10-methylenetetrahydrofolate reductase, a regulatory enzyme in folate metabolism, is important. Studies suggest that the occurrence of genetic hyperhomocysteinemia is linked to MTHFR dysfunction. Aim of the study to investigate whether MTHFR C677T and A1298C polymorphisms and plasma homocysteine levels are risk factors in term of the clinical course of Covid-19 disease in Turkish Society. Study groups were classified into three according to Covid-19 severity: mild (100), moderate (80), severe or critical (80). MTHFR mutations were analysed in 260 patients (126 male, 134 female). Plasma homocysteine levels were detected in 80 patients (40 controls, 40 severe). The analysis of MTHFR mutations were quantified by RTqPCR. Homocysteine levels were measured by HPLC. In according to biochemical data, CRP, AST, ferritin, platelet count, d-dimer, BUN, creatine measurements were higher in the patient group than in the control group, while the lymphocyte count and neutrophil count were lower. Overall, it couldn't find any statistically significant correlation between MTHFR genotypes in patients with Covid-19 infection. However, the average age and the gender of the patient are found to be factors affecting the progression of the disease. The average age and the number of male patients are found to be higher in the severe Covid-19 group than the control group. In addition, the severe Covid-19 group with two genotypes for MTHFR polymorphisms (heterozygous MTHFR 677 C>T and 1298 A>C mutant, homozygous MTHFR 677 C>T mutant) was found to have significantly increased homocysteine levels compared to the control group. It is believed that homocysteine levels could serve as a helpful marker to asses the severity and course of Covid-19.

Abstract

Vortioxetine is a new-generation antidepressant that acts at multiple receptor levels, in addition to exhibiting selective serotonin reuptake inhibitor properties. Recently, studies on the antiproliferative and pro-apoptotic effects of antidepressants have increased. However, there is limited data on the cytotoxic effects of vortioxetine in different cancer cell lines. This study aimed to evaluate the effects of vortioxetine on cell viability in ovarian (A2780), prostate (LNCaP), breast (MCF-7), and colon adenocarcinoma (Caco-2) cell lines. In the study, A2780, LNCaP, MCF-7, and Caco-2 cell lines were treated with vortioxetine at concentrations of 1, 5, 25, 50, and 100 µM for 24 hours. The effect of vortioxetine on cell viability was evaluated using the 3-(4,5-Dimethylthiazol-2-yl)-2,5-Diphenyltetrazolium Bromide (MTT) method and absorbance values were measured at 550 nm. Cell viability was calculated as the percentage change compared to the control group. Half maximal inhibitory concentration (IC_{50}) values were calculated from the dose-response curves generated by GraphPad Prism 8 software. Data were evaluated by non-parametric Kruskal–Wallis analysis and $p<0.05$ was considered statistically significant. When the findings were evaluated, it was determined that vortioxetine application at doses of 5, 25, 50 and 100 µM in A2780, LNCaP and MCF-7 cell lines and at doses of 25, 50 and 100 µM in Caco-2 cell line significantly reduced cell viability ($p<0.05$). Additionally, IC_{50} values were determined as 3.34 µM for A2780, 2.89 µM for LNCaP, 2.18 µM for MCF-7, and 9.95 µM for Caco-2, respectively. This study demonstrates that vortioxetine has significant cytotoxic effects on selected cancer cell lines. These findings suggest that vortioxetine should be evaluated in cancer biology and drug repositioning studies. Further mechanistic analyses (apoptosis, ROS, cell cycle, etc.) are planned to further elucidate the potential anticancer mechanism of vortioxetine.

Vortioksetinin çeşitli kanser hücre hatlarındaki sitotoksik etkisinin değerlendirilmesi

Samet Öz (Orcid: https://orcid.org/0009-0005-8372-8703)

Osmaniye Korkut Ata Üniversitesi, Sağlık Hizmetleri Meslek Yüksekokulu, Veterinerlik Bölümü, Osmaniye, Türkiye

Sorumlu yazar e-mail: sametoz@osmaniye.edu.tr

Özet

Vortioksetin, selektif serotonin geri alım inhibitörü özellik göstermenin yanında çoklu reseptör düzeyinde etki eden yeni nesil bir antidepresandır. Son dönemde antidepresanların antiproliferatif ve pro-apoptotik etkilerine ilişkin çalışmalar artmaktadır. Ancak vortioksetinin farklı kanser hücre hatlarındaki sitotoksik etkileri hakkında sınırlı veri bulunmaktadır. Bu çalışmada vortioksetinin over (A2780), prostat (LNCaP), meme (MCF-7) ve kolon adenokarsinom (Caco-2) hücre hatlarında hücre canlılığı üzerine etkisinin değerlendirilmesi amaçlandı. Çalışmada A2780, LNCaP, MCF-7 ve Caco-2 hücre serileri 24 saat boyunca vortioksetinin 1, 5, 25, 50 ve 100 µM konsantrasyonları ile muamele edildi. Vortioksetinin hücre canlılığı üzerindeki etkisi 3-(4,5-Dimethylthiazol-2-yl)-2,5-Diphenyltetrazolium Bromide (MTT) yöntemi kullanılarak değerlendirildi ve absorbans değerleri 550 nm'de ölçüldü. Hücre canlılığı kontrol grubuna göre yüzde değişim olarak hesaplandı. Yarı maksimal inhibitör konsantrasyon (IC_{50}) değerleri, GraphPad Prism 8 yazılımı ile oluşturulan doz-yanıt eğrilerinden hesaplandı. Veriler non-parametrik Kruskal–Wallis analizi ile değerlendirildi ve $p<0.05$ istatistiksel olarak anlamlı kabul edildi. Bulgular değerlendirildiğinde; A2780, LNCaP ve MCF-7 hücre hatlarında 5, 25, 50 ve 100 µM dozlarında; Caco-2 hücre hattında ise 25, 50 ve 100 µM dozlarında vortioksetin uygulamasının hücre canlılığını anlamlı düzeyde azalttığı tespit edildi ($p<0.05$). Ayrıca IC_{50} değerleri sırasıyla A2780 için 3.34 µM, LNCaP için 2.89 µM, MCF-7 için 2.18 µM ve Caco-2 için 9.95 µM olarak tespit edildi. Bu çalışma, vortioksetinin seçili kanser hücre hatları üzerinde belirgin sitotoksik etkilere sahip olduğunu göstermektedir. Bulgular, vortioksetinin kanser biyolojisi ve ilaç yeniden konumlandırma çalışmalarında değerlendirilmesi gerektiğini işaret etmektedir. Elde edilecek ileri mekanistik analizlerle (apoptoz, ROS, hücre döngüsü vb.) vortioksetinin olası antikanser mekanizmasının daha ayrıntılı şekilde aydınlatılması planlanmaktadır.

Abstract

A highly sensitive and reliable electrochemical sensor was developed for the quantitative determination of the antidepressant drug sertraline HCl (SRT) using a novel screen-printed carbon electrode (SPCE) modified with feather-like Au-Ag-Co trimetallic structures (Au-Ag-Co/SPCE). The trimetallic interface was synthesized by electrochemically to synergistically exploit the outstanding electrical conductivity of Au and Ag together with the catalytic capability of Co, resulting in a superior electron-transfer platform. The morphological and structural features of the materials were thoroughly characterized by SEM, EDX, XRD, and AFM analyses, confirming their homogeneous decoration and well-defined porous structure on the SPCE surface. The electrochemical behavior was investigated using cyclic voltammetry and electrochemical impedance spectroscopy, demonstrating substantially decreased charge-transfer resistance and enhanced redox kinetics after Au-Ag-Co modification. The sensing performance toward SRT HCl was systematically optimized by evaluating the effects of pH, scan rate, accumulation potential, and accumulation time. Differential pulse voltammetry and adsorptive stripping differential pulse voltammetry revealed a strong electrocatalytic response with significantly amplified oxidation currents on Au-Ag-Co/SPCE compared with the bare SPCE. Under optimized conditions, the sensor exhibited a wide linear detection range extending from 2.0×10^{-7} to 2.0×10^{-4} M with two well-defined calibration regions and achieved a remarkably low detection limit suitable for trace-level monitoring. The applicability of the sensor was validated through the analysis of pharmaceutical tablets and spiked human serum samples. High recoveries (97–104%) and low relative standard deviations (<6%) confirmed excellent accuracy, precision, and matrix tolerance. These findings highlight that the Au-Ag-Co/SPCE platform provides rapid analysis, low-cost fabrication, and strong analytical performance, making it a promising candidate for routine quality control, clinical monitoring, and point-of-care testing of sertraline.

Abstract

Cancer is a disease that originates locally and progresses with systemic disturbances arising from a complex interplay of genomic, environmental, and physiological factors, and is characterized by uncontrolled cell proliferation. Among these disturbances, chronic inflammation represents a key tumor microenvironment component that strongly promotes tumor initiation and progression. Given its central role in cancer pathogenesis, compounds with anti-inflammatory activity hold significant potential for developing new therapeutic strategies. Tizanidine is a centrally acting α_2 receptor agonist and muscle relaxant reported to possess anti-inflammatory properties. Recent studies in cancer biology have shown a close association between adrenergic signaling pathways and malignant cellular behavior. In this context, the α_2 agonist activity and anti-inflammatory effects of Tizanidine make it a promising molecule with the potential to influence cancer cell viability. Accordingly, this study investigated the effects of Rupatadine on human ovarian (A2780), colon (Caco-2), and breast (MCF-7) cancer cell lines. In the study, A2780, Caco-2, and MCF-7 cell lines were incubated for 24 hours with Tizanidine concentrations of 1, 5, 25, 50, and 100 µM. The effect of Tizanidine on cell viability was determined using the MTT Assay method. The half-maximal inhibitory concentration (IC_{50}) of Tizanidine was calculated using the GraphPad Prism 8 software. Statistical analyses of the data were performed using the non-parametric Kruskal-Wallis variance analysis, and a $p<0.05$ was considered statistically significant. Analysis of the results showed that Tizanidine significantly decreased cell viability ($p<0.05$) at concentrations of 50 and 100 µM in the A2780 and Caco-2 cell lines, and at concentrations of 25, 50, and 100 µM in the MCF-7 cell line.The findings of this study suggest that Tizanidine may possess cytotoxic activity against A2780, Caco-2, and MCF-7 cells. Tizanidine could be a potential candidate in the development of new cancer treatment strategies through drug repurposing approaches.

Keywords: Tizanidine, Cytotoxicity, A2780, Caco-2, MCF-7

Abstract

Poly(vinyl chloride) (PVC) is widely used in the production of disposable gloves due to its low cost, easy processability, and chemical resistance. However, the phthalate-based plasticizers commonly employed to enhance the flexibility of PVC pose significant health concerns—such as endocrine-disrupting effects and potential carcinogenicity—as well as environmental persistence. In line with European Union REACH regulations and global sustainability frameworks, the demand for safer and environmentally friendly alternative plasticizers has increased considerably. As a result, bio-based plasticizers derived from renewable resources have become an important area of research. In this study, the usability of bio-based plasticizers in PVC-based disposable gloves was investigated using T.B.C supplied by LEBA and AKESBO supplied by AKKİM. For each sample group, ten different formulations containing varying ratios of PVC, bio-based plasticizer, and DOTP were prepared using the dip-coating method. The mechanical properties of the produced gloves were evaluated in accordance with the TS EN 455-2 standard, including tensile strength, elongation at break and elastic modulus. The thermal behavior of the samples was determined through differential scanning calorimetry (DSC) and thermogravimetric analysis (TGA). In addition, physical characteristics such as film flexibility and surface appearance were examined. Statistical analysis methods were used to evaluate the significance of the differences among formulations. The findings of this study are expected to contribute to the identification of the most suitable bio-based plasticizer type and ratio for PVC glove production, while also supporting the development of sustainable, non-toxic, and environmentally friendly products.

Keywords: PVC, bio-based plasticizer, disposable gloves, vinyl gloves

Abstract

Supercapacitors, valued for their rapid energy delivery and durability, require advanced electrode materials for efficient charge–discharge performance [1]. In this study, a ternary MoS_2/rGO/NiMn-LDH nanocomposite was synthesized via a hydrothermal method and successfully employed to modify indium tin oxide (ITO) electrodes. The material was dispersed in 120 µL ethanol and 150 µL deionized water by ultrasonication for 30 minutes, followed by the addition of 50 µL chitosan solution to improve adhesion. The suspension was drop-cast onto a 5 × 5 mm active area of the ITO surface in two layers (10 µL + 10 µL), with each layer dried at 50 °C for 30 minutes to ensure homogeneous coating. Electrochemical performance was investigated using cyclic voltammetry (CV) and electrochemical impedance spectroscopy (EIS) in a ferri/ferrocyanide redox system prepared in KCl–PBS electrolyte. CV results at scan rates ranging from 5 to 200 mV/s revealed that the MoS_2/rGO/NiMn-LDH–modified ITO electrode exhibited significantly enhanced redox peak currents and a markedly larger capacitive area compared with bare ITO, MoS_2-coated ITO, rGO-coated ITO, and rGO/MoS_2-coated ITO electrodes. Such improvements are consistent with previously reported MoS_2/rGO-based hybrid structures, which show strong synergistic effects in electron transfer and charge storage [2]. Even at high scan rates, the ternary nanocomposite maintained improved electrochemical response, indicating fast electron-transfer kinetics and stable capacitive behavior. EIS measurements supported these findings by demonstrating improved charge-transfer characteristics and enhanced interfacial conductivity for the MoS_2/rGO/NiMn-LDH–modified electrode compared with the reference electrodes. Overall, the synthesized nanocomposite shows strong potential for next-generation supercapacitors.

Abstract

The aim of this study was to examine the physical activity levels and body awareness scores of ambulance drivers and to evaluate the relationship between these variables. This cross-sectional study included 50 ambulance drivers aged between 25 and 65 years, who had been driving an ambulance for at least three years and had no health condition that could prevent professional driving. Physical activity levels were assessed using the International Physical Activity Questionnaire (IPAQ), and MET-min/week values were calculated. Body awareness was evaluated with the 18-item Body Awareness Questionnaire (BAQ). Descriptive statistics, Cronbach's alpha, Mann–Whitney U, Kruskal–Wallis and chi-square tests were used for data analysis. The participants had a mean age of 44.08±11.28 years, a mean body mass index (BMI) of 25.86±4.73 kg/m², and an average professional experience of 10.92±1.01 years. Of the drivers, 54% were smokers, 18% held a bachelor's degree, and 26% had an associate degree. The mean physical activity level was 459.88±308.27 MET-min/week; 76% of participants were classified as having a low activity level, while 24% were moderately active. The mean BAQ score was 65.56±10.83. No significant differences were found between BAQ scores and driving duration or professional experience ($p>0.05$). Additionally, no significant associations were identified between physical activity levels and educational status, marital status, or years of experience ($p>0.05$). There was also no statistically significant relationship between physical activity levels and BAQ results ($p>0.05$).

Abstract

Three-dimensional (3D) graphene foam has emerged as a highly promising electrode platform for next generation biosensing, owing to its exceptional ultrahigh surface area, interconnected conductive network, and mechanical toughness. This review emphasises current progress in the design, functionalisation, and application of 3D graphene foam electrodes for electrochemical biosensors. The distinctive architecture of 3D graphene foam provides an exceptionally high specific surface area, optimising biomolecule immobilisation; uninterrupted 3D conductive pathways for swift electron transfer and signal enhancement; significant porosity for effective analyte mass transport; and superior mechanical stability for adaptable device integration. The chemical modification methods, including carboxyl/NHS functionalisation, nanoparticle decorating, and bio-recognition layer assembly, provide enhanced sensitivity and selectivity for clinically relevant analytes. This review sums up current advancements and delineates ongoing problems concerning reproducibility, long-term stability, and scalable production, highlighting the promise of 3D graphene foam as a multifaceted, high-performance material for forthcoming biomedical sensing systems.

Abstract

The development of Alzheimer's Disease (AD) may occur years prior to its first symptoms appearing. Early detection of the Alzheimer's Disease development is crucial for effective clinical intervention and patient management. However, conventional diagnostic techniques, such as positron emission tomography (PET) and cerebrospinal fluid analysis, are expensive, invasive and time-consuming. These limitations have increased the interest in alternate diagnostic approaches utilising AD-related biomarkers found in readily accessible body fluids, such as blood, urine, and saliva. Recent advances in biomarker identification have recognised amyloid beta peptides (e.g., Aβ40 and Aβ42), tau protein isoforms (e.g., tau217, tau181 and tau441), and neurodegeneration-related indicators as potential targets for early AD diagnosis. The advancement of point-of-care (POC) diagnostic devices can create new opportunities for rapid, cheap, and minimally invasive testing. This review will highlight recent development of the detection of body fluid biomarkers with POC devices as well as address the significance of early AD diagnosis. The challenges of the detection of biomarkers with POC devices, such as specificity, sensitivity, and reproducibility, will be addressed.

Keywords: Alzheimer's Disease, point-of-care, diagnosis, body fluids

* Sorumlu yazar e-mail: beyzanur.orhan2021@ogr.yeniyuzyil.edu.tr

Özet

Bu çalışma, *Fusarium spp.*'nin tarımsal ve sağlık üzerindeki ciddi etkileri göz önüne alınarak, patojen ile çeşitli fungal (*Trichoderma*, *Aureobasidium*) ve bakteriyel (*Bacillus*, *Pseudomonas*) biyokontrol ajanları arasındaki etkileşimleri aydınlatmak amacıyla gerçekleştirilen altı farklı transkriptomik (RNA-Seq) analizin meta-analitik bir sentezini sunmaktadır. Projenin temel amacı, bu biyokontrol ajanlarının patojen üzerindeki etki mekanizmalarını gen anlatımı seviyesinde karşılaştırmak ve ortak/benzersiz biyolojik yolları belirleyerek yayınlanabilir bir bütün oluşturmaktır. Tüm çalışmalar için RNA-Seq verileri (NCBI/SRA) toplanmış, FastQC ile kalite kontrolü yapılmış ve sayım matrisleri elde edilmiştir. Diferansiyel İfade Analizi (DEA) DESeq2 paketi kullanılarak gerçekleştirilmiş, anlamlı genler ($|log2\ FC| > 1\ ve\ p_{adj} < 0.05$) belirlenmiştir. Belirlenen DEGs listeleri, Gen Ontolojisi (GO) Zenginleştirme analizi (ShinyGO, Moleküler Fonksiyon) ile fonksiyonel olarak değerlendirilmiştir. Altı çalışma baz alındığında, toplamda 8.765 diferansiyel anlatım gösteren gen (DEG) tespit edilmiştir. En yüksek değişim 4.135 DEG ile *F. pseudograminearum* vs *B. velezensis YB-185* çalışmasında gözlenmiştir. Fonksiyonel analizler, tüm etkileşimlerde patojenin temel olarak transmembran taşıyıcı aktivitesi (iyon, amino asit) ve oksidoredüktaz aktivitesi gibi hücre zarı ve metabolizma ile ilişkili süreçleri hedef aldığını göstermiştir. En çarpıcı bulgu, fungal biyokontrol ajanlarının (*Trichoderma spp.*), *Fusarium*'un TRI ve Aurofusarin (pigment) gen kümelerinde belirgin bir upregülasyonu (savunma/virülans aktivasyonu) tetiklemesi; buna karşın bakteriyel ajanların (*Bacillus spp.*) bu genlerde genellikle downregülasyon yaratarak toksin üretimini başarılı bir şekilde baskılamasıdır. Biyokontrol ajanlarının *Fusarium* üzerindeki moleküler stratejileri, ajanın filogenetik kökenine göre farklılaşmaktadır. Bu çalışma, biyokontrol ajanlarının etki mekanizmalarını transkriptomik düzeyde kıyaslayarak, gelecekteki tarımsal uygulamalar için hedef gen ve yolakların belirlenmesinde kritik bir referans sağlamaktadır.

Anahtar Kelimeler: Transkriptomik, *Fusarium*, Biyokontrol, Diferansiyel Gen İfadesi, Fitopatojen

Özet

Yeni nesil tıbbi tekstiller olarak nitelendirilebilecek nanolifler, yara örtüsü olarak kullanımda büyük bir potansiyele sahiptir. Nanolif yara örtülerinin gözenekli yapısı sayesinde malzemeye, bakteri ve enfeksiyona neden olabilecek maddelerin geçişini engelleyen ve nefes alabilen bir yapı kazandırmakta, aynı zamanda da dermal ve epidermal dokuları kurtarmaya katkı sağlamaktadır. Çalışmamızda yara örtülerinin hazırlanmasında, yenilenebilir kaynaklardan üretilen PLA (Poli Laktik Asit) ve hücre tutunması, çoğalması, kanamayı durdurma (hemostaz) gibi özellikleri bulunan, biyouyumlu, antibakteriyel ve antifungal özelliklere sahip kitosan polimeride kullanılacaktır. Grubumuz tarafından, ilaç etken maddesi olarak kullanılan diklofenak ile antibakteriyel özelliği kanıtlanmış gümüşün bir araya getirilmesiyle [Agdicl] bileşiği sentezlenmiştir. Ayrıca PLA–kitosan ve [Agdicl] içeren polimer çözeltilerine kenevir tohumu yağı, nioli yağı, biberiye yağı, kekik yağı, çay ağacı yağı ve nane yağı gibi çeşitli esansiyel yağlar eklenmiş; bu yağlar aracılığıyla yapıların mekanik özelliklerinin iyileştirilmesi hedeflenmiştir. Literatürde, PLA–kitosan ve [Agdicl] içeriğini farklı esansiyel yağlarla birleştirerek mekanik özellikleri güçlendirmeyi amaçlayan benzer bir çalışmaya rastlanmamıştır. Yapılan çalışmanın sonucunda nanolif oluşumu SEM görüntüleri alınarak, biyokompozitlerdeki katkı maddelerinin PLA ile etkileşimi FTIR spektrumları ile belirlenmiştir. Çekme testi sonuçlarında ise, kenevir tohumu yağı eklenen biyokompozit yara örtüsünün diğer eklenen esansiyel yağlara göre en yüksek mekanik dayanımı sergilediği görülmüştür. Üretilen yara örtüsü ile gaz alış-verişine izin veren, hastaları bakteri ve mantar enfeksiyonuna karşı koruyacak, yarada meydana gelen ağrı ve acıyı dinderecek, hemde iltihap önleyici aynı zamanda da yarada meydana gelecek olan kan ve akıntıları emecek özellikte tamamen biyouyumlu ve mekanik özellikleri yüksek bir yara örtüsü üretimi yapılarak hastaların iyileşme sürecini hızlandıracağı ve günlük yaşantılarını kolaylaştıracağı düşünülmektedir.

Anahtar Kelimeler: PLA, Yara örtüsü, Elektrospinning, Esansiyel yağ.

Abstract

Actinobacteria are Gram-positive bacteria widely found in both terrestrial and aquatic ecosystems with high biotechnological potential. They are generally aerobic microorganisms that form mycelia, have conical structures, and exhibit colony morphologies producing various pigments. These plants, which can reproduce by binary fission and the production of spores or chondroitin, have attracted increasing interest in recent years, particularly in plant biotechnology. Their antagonistic activities against plant pathogens suggest that they offer significant potential in biological control processes. Actinobacteria contribute to carbon cycle by degrading complex organic molecules such as cellulose and chitin through the enzymes they produce. Thus, they play a crucial role in the renewal of nutrients in soil and the formation of humus. Furthermore, their capacity to produce secondary metabolites makes them commercially and pharmaceutically valuable. Many important antibiotics, such as streptomycin, terramycin, and auremycin, were first isolated from actinobacteria. Therefore, actinobacteria were isolated from soil samples collected from the districts of Posof (Gümüşkavak), Damal (Tepeköy), and Hanak (Selamverdi) in Ardahan, as well as from the Mera (Dumankonak) and Değirmenli regions. In this study, the dilution–plate method was applied, and after 14 days of incubation at 28 °C, pure cultures were obtained from actinobacterial colonies grown on 10 different selective media. Based on color grouping and colony morphology, 47 isolates exhibiting actinobacterial characteristics were selected for molecular identification. In addition, to determine the antimicrobial potential of these isolates, antimicrobial activity tests will be performed against 15 pathogenic organisms using the agar plug diffusion technique, and molecular typing will be conducted according to 16S rRNA gene region sequence analyses.

Abstract

This study aimed to investigate the seasonal variations in the phosphatidylinositol (PI) fatty acid composition of muscle tissues in male and female *Silurus triostegus*. Analyses revealed that the major fatty acids of the PI fraction were 16:0, 18:0, 18:1n-9, 20:4n-6, 20:5n-3, and 22:6n-3. Seasonal evaluations demonstrated pronounced sex- and season-dependent differences in both individual fatty acids and total SFA, MUFA, and PUFA levels. The fatty acid 12:0 was markedly elevated in April in both sexes and additionally in October in males. The 14:0 fatty acid reached its highest level in January in both sexes. The dominant SFAs, 16:0 and 18:0, exhibited distinct seasonal patterns: 16:0 peaked in July in both sexes, whereas 18:0 was highest in July in males and in April and October in females. The major MUFA, 18:1n-9, showed its maximum proportion in January and its minimum in April. Among PUFAs, 18:2n-6 increased in July in both sexes and decreased to its lowest level in April. EPA (20:5n-3), DPA (22:5n-3), and DHA (22:6n-3) increased sharply in April and decreased in July. Total SFA reached its highest level in July, while total MUFA peaked in January. Total PUFA increased in April and declined in July in both sexes. Seasonal fatty acid distribution patterns were determined as follows: in January, males exhibited SFA>MUFA>PUFA and females SFA>MUFA=PUFA; in April and October, both sexes showed SFA>PUFA>MUFA; and in July, both sexes exhibited SFA>MUFA=PUFA. Omega-3 fatty acids were highest in April and lowest in January, while omega-6 fatty acids were highest in October in males and in July in females. The ω3/ω6 ratio peaked in April and reached its minimum in October. Overall, these findings demonstrate that PI fatty acid composition in the muscle tissue of *S. triostegus* undergoes significant seasonal and sex-dependent variation.

Analysis of tumor mutational burden and mutation status in immunotherapy-treated lung adenocarcinomas

Ayça Tan

Manisa Celal Bayar University, Facukty of Medicine, Department of Pathology, Manisa, Türkiye

Corresponding author e-mail: draycatan@gmail.com

Abstract

Immune checkpoint inhibitor therapies are used in metastatic lung adenocarcinomas, and the effectiveness of these treatments is associated with certain biomarkers (tumor mutational burden (TMB)) and tumor mutation profile. To predict this relationship, clinical and genomic data were compared with survival status in lung adenocarcinoma patients who received immunotherapy. This study used the cBioPortal for Cancer Genomics, an open-access bioinformatics database. The most frequently mutated genes and the effect of TMB on immunotherapy were examined. Of 255 lung adenocarcinoma cases treated with PD1/PD-L1, 142 (55.7%) were female. The three most frequently mutated genes were TP53 (58.8%), KRAS (40.8%), and STK11 (25.5%). TMB was ≥10 in 83 (32.5%) of the cases. Cases with a TMB ≥10 had a better prognosis, and mutations were observed more frequently in 60 genes in this group of cases and were statistically significant ($p<0.001$). Mutations were more common in the ERBB4 gene in the TP53 mutant group and in the KRAS and STK11 genes in the non-TP53 group ($p<0.001$). Mutations in the EGFR and TP53 genes were more common in non-KRAS group ($p<0.001$). Mutations in the KEAP1 and KDR genes were more common in those with STK11 mutations, and TP53 and EGFR mutations were more common in the non-STK11 group ($p<0.001$). Those with STK11 mutations had a poorer prognosis ($p>0.05$). Conclusion: Immunotherapy treatments are routinely used and promising in lung adenocarcinomas. Although the oncological outcomes of the cases treated with this treatment in the first two years showed clinically significant differences, specifically in TP53, KRAS and STK11 mutations and TMB, it was noted that there were no significant differences due to these mutations and TMB after two years

Abstract

Nowadays, the widespread and inappropriate use of antibiotics, particularly in the treatment of infected wounds, has contributed to the emergence of multidrug-resistant bacterial strains, thereby significantly limiting the effectiveness of current therapeutic approaches. Therefore, the development of novel agents with potent antibacterial activity and advanced wound-dressing materials has become increasingly important [1,2]. In recent years, hydrogels have emerged as prominent materials in wound care, supporting the development of intelligent systems that facilitate wound healing. Due to their high water content and three-dimensional crosslinked polymeric network structures, hydrogels can maintain a moist wound microenvironment, provide oxygen permeability, and prevent adhesion to the wound surface. Additionally, the physical, chemical, and biological properties of hydrogels can be tailored by adjusting the type of crosslinking, polymer composition, and incorporated functional groups [3,4]. A promising strategy for imparting antibacterial properties is the integration of metal complexes into the hydrogel matrix. Hydrazone ligands bearing an azomethine (–C=N–) group can readily bind metal ions to form stable metal complexes, thereby enhancing antibacterial efficacy [5]. In this study, antibacterial hydrogels were developed using a Cu(II) hydrazone complex. First, a novel hydrazone ligand was synthesized from 2,4-dihydroxybenzaldehyde and valeric acid hydrazide, and its Cu(II) complex was subsequently prepared. The structures were characterized by various spectroscopic and analytical techniques. Subsequently, hydrogels containing the metal complex at different concentrations were fabricated using natural polymers. The antibacterial activity of the obtained hydrogels against *E. coli* ATCC 25922 and *S. aureus* ATCC 25923 was evaluated using the disk diffusion method. The results demonstrated an apparent antibacterial effect against both bacterial strains, becoming more pronounced with increasing copper complex concentration.

Keywords: Hydrazone ligand, Cu(II) complex, Antibacterial hydrogel

Abstract

Levulinic acid (LA) is a primary organic compound and one of the twelve primary building blocks derived from the breakdown of lignocellulosic biomass. The conversion of levulinic acid into several valuable substances has been the subject of academic research over a few decades. The efficiency of various heterogeneous catalysts such as acidic ion exchange resins, zeolites, heteropolyacids, metal organic frameworks, carbon materials were documented in the conversion of levulinic acid. Despite the efficacy of these potential heterogeneous catalysts in facilitating the conversion of levulinic acid (LA) to n-butyl levulinate (BL), their high cost, susceptibility to leaching of active sites, and poor catalytic activity limits their practical applicability. So, in this study, a deep eutectic solvents was used as a sustainable, environmentally friendly, acidic catalyst. This work examined the esterification of levulinic acid with butanol using an acidic deep eutectic solvent (DES) composed of choline chloride and para-toluene sulfonic acid. DESs consist of two or more constituents that create a eutectic mixture by hydrogen bonding, leading to melting points that are lower than that of the individual components. These solvents contain two primary constituents: a hydrogen bond donor (HBD) and a hydrogen bond acceptor (HBA). Recently, DESs have been used as an alternative to traditional solvents due to their stability at higher temperatures, lower vapor pressure, combustion-free nature, and capacity for tuning. In butyl levulinate synthesis, over 90% conversion of levulinic acid was achieved within 15 minutes in the microwave reactor. The results show that DES can be an efficient catalytic system in the transformation of levulinic acid.

Özet

Bu çalışmada, Erzincan'a endemik olarak yayılım gösteren *Helichrysum arenarium* subsp. *erzincanicum* bitkisinin fitokimyasal içeriğinin belirlenmesi ve antioksidan kapasitesinin değerlendirilmesi amaçlanmıştır. Bu kapsamda, Erzincan, İliç-Kuruçay bölgesinden toplanan bitkinin ilk olarak metanol-su ekstraktı hazırlanmış ve bu ekstraktın antioksidan biyolojik aktivitesi DPPH• radikal giderme, Ferrik İndirgeyici Antioksidan Güç (FRAP), toplam fenolik ve toplam flavonoid içerikleri üzerinden değerlendirilmiştir. Bitki ekstraktının fitokimyasal içeriğinin belirlenmesi Sefadeks ve Silika jel kolonlar aracılığıyla gerçekleştirilen kromatografik işlemlerle yapılmıştır. Thin Layer Chromatography (TLC) ile yeterli ayrımı sağlanan elüatlar yüksek performanslı sıvı kromatografisi (HPLC) ile detaylı analize tabi tutulmuştur. Analitik-HPLC saflık kontrolünün ardından preparatif HPLC'ye geçilmiş olup eluatların yarı otomatik biçimde ayrımları sağlanmıştır. Elde edilen saf bileşiklerin yapıları Nükleer manyetik rezonans (NMR) tekniği ile aydınlığa kavuşturulmuştur. Elde edilen bulgular *Helichrysm arenarium* subsp. *erzincanicum* bitkisinden elde edilen ekstrenin standart antioksidan kaynağı olarak kullanılan troloks, askorbik asit, BHT ve BHA ile kıyaslandığında istatiksel olarak kayda değer ölçüde antioksidan aktivite gücüne sahip olduğu belirlenmiştir. İzolasyon ve yapı analiz sonuçları bitkinin fitokimyasal içerik bakımından oldukça zengin bir içeriğe sahip olduğunu göstermiştir. Sonuç olarak, bu çalışmadan elde edilen tüm bu bulgular *Helichrysm arenarium* subsp. *erzincanicum* türünün zengin fitokimyasal içeriğiyle önemli derecede *in vitro* antioksidan etkiye sahip olduğunu ve bunun da *in vivo* çalışmalara kapı araladığını ortaya koymaktadır.

Anahtar Kelime: Antioksidan aktivite, Fitokimyasal içerik, *Helichrysum arenarium* subsp. *erzincanicum*, HPLC, NMR.

Özet

Küresel enerji ihtiyacı gün geçtikçe artmaktadır. Fosil yakıtlara olan bağımlılığı azaltacak sürdürülebilir temiz enerji kaynaklarının geliştirilmesi bir zorunluluk haline gelmiştir. Yenilenebilir teknolojiler temiz enerji kaynakları olarak kabul edilir. Bu kaynakların uygun şekilde kullanılması, çevresel kirliliği azaltırken, aynı zamanda minimum atık, ekonomik ve sosyal ihtiyaçları da sürdürülebilir kılar. Bu etkenler doğrultusunda önemli bir temiz enerji kaynağı olan güneş hücrelerinin kullanımının artması ve bu sistemlerden maksimum verim elde edilmesi oldukça önemlidir. ABD Ulusal Yenilenebilir Enerji Laboratuvarı (NREL)'in yayınladığı verilere göre, günümüzde ticari olarak en yaygın kullanıma sahip monokristal ve polikristal güneş panellerinin yaklaşık ~%15-%22 arasında bir verimlilikte olması oldukça düşündürücüdür. Bugüne kadar en yüksek verim olarak açıklanan tandem güneş hücreleri bile ~%48 enerji dönüşüm verimliliğine sahiptir ve geliştirilmeye muhtaçtır. Bu bilgilerden yola çıkarak çalışmanın temel amacı: monokristal ve polikristal güneş hücrelerinin verimliliğinin artırılması olarak belirlenmiştir. Kuantum noktaları (QDs), yarıiletken malzemelerden yapılmış olup, ayarlanabilir fiziksel boyutlara ve olağanüstü optoelektronik özelliklere sahiptir. Son yıllarda, QD'ların boyut kısıtlaması ve anizotropik geometrileri nedeniyle elektrokimyasal enerji depolama alanında ve fotovoltaik sistemlerde kullanımı araştırılmaktadır (Wu ve ark., 2018). Bu nedenlerden dolayı çalışmayı, QD'ların güneş hücrelerinin verimliliğini artırma üzerine olmuştur. Düşük maliyet, basit sentez prosedürleri ve iyi kimyasal özellikler göstermelerinden dolayı karbon QD(C-QDs)'lar ve ZnO QD'lar tercih edilmiştir. Basit bir sentez yöntemi olması, malzeme kaybının sıfıra yakın olması ve yüksek maliyet gerektirmemesi gibi nedenlerden dolayı hidrotermal sentez yöntemi tercih edilmiştir. Sentez sonucunda ~2-5 nm çaplara sahip QD'lar elde edilmiştir ve UV ışık altında mavi ışık verdiği tespit edilmiştir. Elde edilen QD'lar, UV-vis, FT-IR, TEM, XRD ve PL analizleri yapılarak karakterize edilmiştir.

Anahtar Kelimeler: Karbon kuantum noktalar (C-QDs), Metal oksit kuantum noktalar (ZnO-QDs), Hidrotermal sentez yöntemi, Monokristal güneş hücreleri, Polikristal güneş hücreleri

Abstract

Endometrial microbiota has emerged as a critical regulator of uterine health and reproductive outcomes. Recent studies highlight the association between microbial composition and histopathological changes in the endometrium, including inflammation, polyps, and altered tissue integrity, which can directly influence implantation success and IVF outcomes. Dysbiosis of the endometrial microbiome has been linked to recurrent implantation failure, infertility, and pregnancy loss. Histological evaluation reveals that shifts in microbial populations can modify the endometrial immune environment, angiogenesis, and stromal-epithelial interactions, underscoring the interplay between microbiota and tissue morphology. Understanding these histological correlations provides valuable insights for optimizing embryo transfer strategies, improving implantation rates, and developing targeted interventions to restore endometrial homeostasis. This review integrates current evidence on the role of endometrial microbiota in reproductive health, emphasizing histological features that can inform clinical decisions in assisted reproductive technologies.

Keywords: Endometrial microbiota, histology, fertility, IVF, implantation, reproductive health

Özet

Endüstriyel faaliyetler sonucu su kaynaklarında biriken organik boyalar ve diğer kalıcı kirleticilerin etkin bir şekilde giderilmesi, sürdürülebilir çevre teknolojilerinin ve yeni nesil adsorbent malzemelerin geliştirilmesini zorunlu kılmaktadır. Bu kapsamda, düşük maliyetli, çevre dostu ve yüksek performanslı adsorbentlerin geliştirilmesi önem kazanırken, tarımsal atıkların fonksiyonel karbon bazlı malzemelere dönüştürülmesi hem döngüsel ekonomi ilkeleriyle uyumlu bir değerlendirme stratejisi sunmakta hem de su arıtım süreçleri için yenilikçi çözümler sağlamaktadır. Bu doğrultuda, biyocharların manyetik özelliklerle zenginleştirilmesi; kolay geri kazanılabilirlik, yüzey reaktivitesi ve çok yönlü fonksiyonelleştirme imkânı sayesinde çevresel iyileştirme uygulamalarında öne çıkan bir yaklaşım haline gelmiştir. Bu çalışmanın amacı, mısır kabuğu atıklarından iki farklı üretim stratejisiyle manyetik biyochar sentezlemek, bu iki yöntemin termal davranış, kompozisyon ve yüzey fonksiyonelliği üzerindeki etkilerini karşılaştırmalı olarak incelemek ve elde edilen malzemelerin metilen mavisi adsorpsiyonundaki potansiyelini değerlendirmektir. Bu doğrultuda, birinci yöntemde biyokütle Fe^{2+}/Fe^{3+} çözeltileriyle ön işlemden geçirilmiş ve ardından 400 °C sıcaklık, 20°C/dak ısıtma hızı ve 1,5 saat kalma süresi koşullarında piroliz edilerek in-situ manyetizasyon sağlayan Pre-Fe–Pyro örneği elde edilmiştir. İkinci yöntemde ise biyokütleden 400 °C sıcaklık, 20°C/dak ısıtma hızı ve 1,5 saat kalma süresi koşullarında piroliz edilerek üretilen biyochar, demir çözeltileriyle işlemden geçirilerek ex-situ manyetik modifikasyon içeren Pyro–Post-Fe örneği hazırlanmıştır. Elde edilen manyetik biyocharlar, FTIR, TGA ve SEM ile karakterize edilmiştir ve bunların elemental ve proximate içerikleri TGA dataları kullanılarak hesaplanmıştır. Sonuçlar, iki sentez yönteminin malzemelerin yüzey kimyası, termal dayanımı ve inorganik/organik bileşen dağılımı üzerinde belirgin farklılıklar oluşturduğunu göstermektedir. Özellikle Pre-Fe–Pyro yönteminde demir türlerinin piroliz sırasında biyokütle yapısına daha homojen şekilde gömülmesi, kül oranı ve bozunma profillerinde karakteristik değişimler oluşturmuştur. Üretilen manyetik biyochar örnekleri, model kirletici olarak metilen mavisinin adsorpsiyonunda test edilmekte olup, düşük maliyetli, yeniden kullanılabilir ve çevre dostu adsorbent geliştirilmesi açısından önemli bir potansiyel sunmaktadır. Bu çalışma, mısır bitkisi atığının katma değerli bir çevresel malzemeye dönüştürülmesi için etkili ve uygulanabilir bir yöntem ortaya koymaktadır.

Abstract

The need to reduce energy consumption, thermal damage, and the use of chemical preservatives in food processing and preservation has made cold plasma one of the prominent non-thermal technologies in recent years. Cold plasma generated at atmospheric or low pressure can effectively inactivate microorganisms, spores, and certain enzymes through reactive oxygen and nitrogen species, ions, free radicals, and UV radiation, while the limited increase in process temperature allows for the preservation of heat-sensitive food components. This work provides a comprehensive overview of the applications of cold plasma technology in the food industry, its mechanisms of action, and its implications for product quality. The effects of different plasma generation systems (spark discharges, dielectric barrier discharges, and atmospheric pressure plasma jets (APPJ)) and processing parameters on microbial safety, shelf life, food constituents (proteins, lipids, carbohydrates, bioactive compounds), and sensory attributes will be evaluated. Findings reported for different product categories, including fresh fruits and vegetables, meat and meat products, milk and dairy products, cereals and bakery goods, fruit juices, and nuts, will be comparatively assessed in order to highlight the advantages and limitations of the technology. In addition, the use of cold plasma as a decontamination tool for packaging materials and food-contact surfaces will be examined in the context of potential oxidative side reactions, process standardization, scale-up, toxicological assessment, and regulatory requirements, with emphasis on existing knowledge gaps. This study aims to provide an up-to-date framework for the safety- and quality-oriented sustainable applications of cold plasma in the food sector and to identify priority areas for future research for both industry and academia.

Keywords: cold plasma, non-thermal food processing, microbial inactivation, food quality, food safety

Özet

Diyabetik, bası ve yanık gibi kronik yara tiplerinde inflamasyonun uzun sürmesi, mikrobiyal kontaminasyon riski ve doku rejenerasyonunun yetersizliği, gelişmiş ve çok işlevli yara örtülerinin geliştirilmesini gerektirmektedir. Bu kapsamda hem antimikrobiyal koruma sağlayabilen hem de doku yenilenmesini destekleyebilen biyolojik ve fonksiyonel ajanların kullanımı modern yara yönetimi için önemli bir yaklaşım oluşturmaktadır. Fitoterapötik özellikleri literatürde iyi bilinen *Plantago lanceolata* (sinir otu), anti-inflamatuar, antimikrobiyal, antifungal ve yara iyileştirici bileşenleri sayesinde bu tür biyomalzeme tasarımları için güçlü bir adaydır. Bu çalışmanın amacı, fitoterapötik özelliklere sahip sinir otu ekstraktı içeren GelMA tabanlı mikroiğne yapısı ile antimikrobiyal etkili, yeşil sentezle üretilmiş çinko-oksit (ZnO) nanopartikülleri içeren kitosan–PVA fiber katmanını bir araya getirerek biyouyumlu ve fonksiyonel bir iki katmanlı yara örtüsü geliştirmektir. Bu kapsamda, alt katman olarak GelMA–Sinir otu ekstraktı kompozit mikroiğneleri, DLP (Digital Light Processing) 3B baskı teknolojisiyle üretilmiş; üst katman ise yeşil sentezle üretilmiş ZnO nanopartikülleri içeren kitosan–PVA fiber yapı elektrospinning yöntemiyle hazırlanmıştır. Elde edilen çift katmanlı mikroiğne yapısı, sinir otu ekstraktı, ZnO nanopartikülleri ve kitosan–PVA nanofiber üst katmanın karakterizasyonu için FTIR, SEM ve antimikrobiyal aktivite analizleri yapılmış olup; bu analizler, bitkisel ekstraktın mikroiğne yapısına kimyasal olarak başarıyla entegre edildiğini, ZnO nanopartiküllerinin fiber mat içinde homojen şekilde dağıldığını ve her iki katmanın da belirgin antimikrobiyal aktivite sergilediğini göstermiştir. Geliştirilen iki katmanlı kompozit yapının ayrıca mekanik özellikleri, hidrasyon davranışı, ilaç salım profilleri ve biyouyumluluğunun ileri testlerle değerlendirilmesi planlanmakta olup, bu çalışma kronik yaraların tedavisinde yüksek potansiyel sunan yenilikçi bir yara örtüsü tasarımı ortaya koymaktadır.

Anahtar kelimeler: Mikroiğne, DLP Biyobaskı, Elekrospinning, Sinir otu, ZnO nanopartikül.

Abstract

Diabetes mellitus is a group of metabolic disorders featuring hyperglycaemia caused by defects in insulin secretion, insulin utilisation, or both. This study aims to investigate the effects of early-onset, untreated diabetes on muscle strength and reflexes in juvenile rats using an experimental diabetes model. For this purpose, 14 male Wistar albino rats, 21 days old and weaned, were used. After a 1-week adaptation period, on day 29, to establish the diabetes model, 120 mg/kg streptozotocin (STZ) was administered to the experimental group (n=7). In contrast, 1 ml/kg physiological saline was administered to the control group (n=7). A blood glucose level of 300 mg/dl was accepted as confirmation of diabetes. On day 30, blood glucose levels were measured in the tail veins of the subjects using a glucometer. On day 41, the subjects underwent a weight test, a Kondizella inverted screen test, a forelimb flexion test, a hindlimb flexion test, a visually triggered placement test, a contact-triggered placing test, and a hindpaw grasping reflex test. Ethical approval for the study was obtained from Balıkesir University (Approval number: 2025/5-26, Meeting date: 22.05.2025). The distribution was examined using the Shapiro-Wilk test. The parametric Student's t-test or the nonparametric Mann-Whitney U test was applied. Blood glucose levels of the subjects were found to be between 424 and 600 mg/dl in the initial birth test and above 300 mg/dl in subsequent measurements ($p<0.001$). No significant difference was found in reflex measurements and reflex responses ($p>0.05$). Diabetic subjects had significantly shorter times in the weight test and Kondizella inverted screen test ($p<0.05$). The study examined the reflexes and muscle strength of diabetic rats that had not received treatment before adolescence. A decrease in muscle strength was observed, while reflex measurements were normal. More detailed studies are required.

Keywords: Adolescence, Diabetes Mellitus, Muscle Strength, Reflexes, Streptozotocin

Abstract

Mutation breeding in soybean (*Glycine max* L. Merr.) is a promising strategy to develop novel and superior varieties by enhancing genetic variation. Gamma radiation, as a physical mutagen, is widely employed in this process. However, determining the optimal mutagen dose is crucial; therefore, this study investigated the effects of gamma radiation on two soybean cultivars, Adel and Lider. Seeds were exposed to Co-60 gamma ray doses ranging from 0 Gy (control) to 500 Gy. The objective was to assess the impact of varying radiation doses on early growth —including germination rate, seedling growth traits, and biomass — parameters in the M1 generation and to determine the optimal dose for mutation breeding by evaluating lethal dose (LD50) and growth reduction (GR50) values. The results demonstrated a significant dose-dependent inhibitory effect on all measured traits. For instance, at 500 Gy, germination percentage and dry weight were reduced to 34.7% and 25.2% of the control, respectively. The LD50 for germination was estimated between 300-400 Gy, while the GR50 for seedling growth was around 300 Gy. In conclusion, the 200-300 Gy dose range is recommended as optimal for soybean mutation breeding, effectively balancing mutation induction with acceptable plant survival and growth.

Abstract

From past to present, many taxonomic, biogeographic, physiological, and ethological studies have been conducted on insects. Today, these studies have shifted to faster methods and have been reduced to the molecular level. The use of insect DNA in gene and gene expression studies has become widespread and is frequently applied to all insect groups. Early detection and monitoring of economically significant pests is critical to prevent their spread and establishment in valuable commercial products. To achieve this, fast and accurate species identification tools are required. The most crucial step of rapid techniques such as DNA barcoding is the acquisition of high-quality and high-concentration genomic DNA. Based on this, many different methods have been developed for genomic DNA isolation. Obtaining dense and high-quality DNA is also one of the important factors for the studies to be conducted. In this study, different DNA isolation methods frequently applied in the literature were compared using the species *Simulium bezzii*, known to be a vector of many diseases, and it was investigated which method yielded genomic DNA at higher concentrations. Three different isolation methods were evaluated: a manual isolation method, a low-cost commercial kit, and a high-cost commercial kit. After isolation, the concentrations of both total DNA and the products of the mtCOI gene region amplified by PCR were measured using a Nanodrop device. The comparison of the obtained data revealed that the highest yield in total DNA acquisition was achieved with the manual method, followed by the high-cost commercial kit, and finally the low-cost commercial kit. The concentration measurements of PCR products did not show a significant difference among the groups. These results suggest that the manual isolation method may be a suitable alternative for obtaining high-quality genomic DNA from the species *Simulium bezzii* in terms of cost and efficiency. Additionally, it was understood that PCR success could occur at a similar level regardless of the isolation method chosen.

Abstract

Breast Cancer (BC) is a leading cause of global cancer mortality, characterized by significant heterogeneity. The highly invasive MDA-MB-231 cell line, an in vitro TNBC model, relies on the constitutive activation of the JAK/STAT pathway for proliferation and apoptosis resistance. Although the JAK inhibitor Ruxolitinib is known to suppress STAT3 phosphorylation, inhibit tumor progression, and induce apoptosis in MDA-MB-231 cells, and Liquidambar orientalis extract exhibits independent anticancer properties, the synergistic effect of their combination in this cell line remains unelucidated. Therefore, this study aims to investigate the synergistic anticancer potential of combining Ruxolitinib and Liquidambar orientalis extract by examining their in vitro effects on apoptotic mechanisms in MDA-MB-231 cells. MDA-MB-231 cells were cultured. The drug doses were determined by MTT analysis. Cellular migration capacity was assessed using a wound healing assay. The DNA laddering assay was utilized to evaluate DNA fragmentation, a hallmark of apoptosis. Cell viability analyses showed that while both agents alone reduced viability, the combination group demonstrated a more pronounced reduction, suggesting a synergistic or additive effect. The wound healing assay revealed significantly suppressed cell migration in the treated groups, demonstrating that the agents effectively inhibited cellular motility and reduced metastatic potential. Furthermore, the combination treatment led to the formation of characteristic DNA ladder structures, confirming active induction of apoptosis. The combination of Ruxolitinib and *Liquidambar orientalis* demonstrates potent antiproliferative, anti-metastatic, and pro-apoptotic effects in MDA-MB-231 cells, suggesting its potential as an adjuvant therapeutic option for TNBC. This study offers a scientific contribution to developing new therapeutic strategies. Further investigation into the underlying molecular mechanisms is recommended through advanced gene expression, protein level, and signaling pathway analyses.

Lilium akkussianum and conservation priorities for Turkey's endemic *Lilium* Species: Habitat requirements and threat analysis

Hakan Yılmaz (Orcıd: https://orcid.org/0000-0002-0113-8277)

Ordu University, Akkuş Vocational School, Environmental Health and Environmental Risk Management Technician Program

Corresponding author e-mail: hakanyilmaz@odu.edu.tr

Abstract

Turkey is an important biodiversity hotspot, home to many endemic species of the genus *Lilium*. This review aims to evaluate the ecological requirements, habitat preferences, and threats faced by the species *Lilium akkussianum*, which has a limited distribution, in light of the current scientific literature. The assessments revealed that *L. akkussianum* exhibits high sensitivity to microhabitat parameters such as light intensity, soil moisture content, and pH level. The fact that its populations are mostly concentrated in isolated and narrow localities makes the species highly vulnerable to habitat destruction. Increasing agricultural activities, infrastructure works (road construction), mining operations, and microclimatic disturbances caused by global climate change in the region stand out as key anthropogenic factors threatening the species' sustainability. Comparisons with other *Lilium* species in Turkey demonstrate the critical importance of ecological niche modeling and long-term population monitoring programs in conservation prioritization efforts. This review provides a science-based framework for developing effective conservation strategies applicable both to *L. akkussianum* specifically and to endemic *Lilium* species in general.

Keywords: *Lilium akkussianum*, endemism, conservation biology, habitat analysis, ecological niche, threat assessment.

Abstract

Chemical warfare agents (CWAs) are toxic chemicals developed for conflict that pose serious threats to global security and public health. VX, or Ethyl S-2-diisopropylaminoethyl methylphosphonothiolate, is a highly toxic nerve agent and one of the most lethal CWAs, classified as a Schedule 1.A.03 chemical under the Chemical Weapons Convention (CWC). To enforce the CWC, the Organisation for the Prohibition of Chemical Weapons (OPCW) conducts proficiency tests (PTs) as international exercises to verify laboratories' analytical capabilities in detecting such agents. This study aimed to identify VX and possible related compounds in environmental samples using advanced analytical techniques such as multimodal mass spectrometric confirmation. In this study, we implemented a comprehensive analytical strategy to identify and confirm the nerve agent VX and structurally related compounds. We employed a multi-technique approach combining gas chromatography–mass spectrometry with electron ionization and chemical ionization (GC-EI/MS, GC-CI/MS) and liquid chromatography–electrospray ionization tandem mass spectrometry (LC-ESI-MS/MS). Sample preparation included selective derivatization (e.g. trimethylsilylation) to enable GC-MS analysis of polar organophosphorus analytes, while direct LC-MS/MS was applied for confirmatory analysis. In the context of the OPCW's 55th Proficiency Test (PT-55), VX and several key degradation or reaction products – methylphosphonic acid, ethyl methylphosphonate, 2-(N,N-diisopropylamino)ethanesulfonic acid, bis(2-N,N-diisopropylaminoethyl)disulphide, S-2-Diisopropylaminoethyl methylphosphonothiolate, O-Ethyl methylphosphonothiolate, and 2-(N,N-Diisopropylamino)ethanol – were successfully detected and confirmed in full compliance with OPCW validation criteria. This work demonstrates methodological rigor and analytical innovation in support of the CWC verification framework. The successful confirmation of VX and its analogues – compounds of great concern due to their extreme toxicity and prohibition – highlights the critical role of advanced chromatography–mass spectrometry techniques in upholding international non-proliferation agreements. Accurate chemical identification and confirmation not only ensure compliance with the CWC but also strengthen global trust in verification regimes by providing unequivocal evidence needed for enforcement and attribution.

Keywords: Chemical warfare agents, VX nerve agent, chromatography, mass-spectrometry.

Corresponding author e-mail: esen.poyraz@cbu.edu.tr

Abstract

The posterior silk gland is the part of the silk gland that synthesizes the main silk protein, fibroin, in the abdominal cavity of the larva and degenerates under physiological conditions during larval pupal metamorphosis in Lepidopteran. Degeneration of larval-specific tissues and organs occurs via programmed cell death, apoptosis and autophagy, under the control of the endocrine system. Developmental alterations and specific markers of autophagic and apoptotic cell death mechanisms of posterior silk gland were investigated during the larval-pupal metamorphosis from the first day of the last larval stage until the 36th hour of the pupal stage. In this process, morphological examinations were investigated by phase contrast microscopy and routine histological techniques under light microscope. For autophagic cell death, determination of lysosomal acid phosphatase enzyme activity, expression profiles of marker genes, ATG6 and ATG8, by qRT-PCR, and determination of localization and density of lysosomes with Lyso-Tracker, a lysosomal marker dye, were used. Specific marker of apoptosis was investigated by TUNEL method. The effects of the insect hormone 20HE, known to be the main factor in the initiation of programmed cell death, were determined by the western blotting method of the receptor isoform of ecdysone, EcR-B1, and it was determined that EcR-B1 was predominantly produced in the posterior silk gland.
The results show that although autophagy mainly plays a protective role for the cell, if it proceeds unhindered above a certain threshold value, it can lead to the stimulation of the expression of cell death markers and activation of the apoptotic pathway, and that ecdysone plays a role in the process via the EcR-B1 isoform.

Keywords: ATG6, ATG8, apoptosis, autophagy, EcR-B1, *Galleria mellonella*.

Abstract

Alzheimer's disease is a neurodegenerative disorder that causes progressive damage to the brain. It is the most common type of dementia. The number of dementia/Alzheimer's cases is expected to reach around 140 million by 2050 (WHO, 2025). Triazole hybrids represent a promising frontier in medicinal chemistry, with their ability to integrate diverse pharmacophores into a single scaffold offering a powerful strategy for drug design. As research advances, the development of multifunctional triazole-based hybrids is anticipated to address major global health challenges, particularly in combating antimicrobial resistance, cancer heterogeneity, and chronic inflammatory diseases (Avuthu et al., 2025; El-Lateef et al., 2025). In this study, five new triazole compounds were synthesized in high yields, and their characterizations were carried out using FTIR, ^{1}H NMR, and ^{13}C NMR techniques (Figure 1). The interactions of the synthesized compounds with AChE and MRSA-associated proteins (4EY7, 1ZGC, and 3ZG5) were determined through molecular docking studies. According to the obtained results, the compounds were found to exhibit strong interactions with the specified proteins.

Abstract

Microplastic pollution has been identified as a significant environmental threat that has rapidly increased in both terrestrial and agricultural ecosystems over the past decade. This review systematically analyzes current research on the effects of microplastics on soil physical properties, microbial activity, water movement, and plant root development. The potential of different polymer types, particularly polystyrene, to loosen soil structure, alter porosity, and disrupt aggregate stability has been clearly demonstrated by data from the literature. Furthermore, the uptake of microplastics by plants through their roots, their transport via xylem and phloem, whether they reach leaf tissues, and the changes they cause in physiological processes (photosynthesis, stomatal behavior, nutrient content) have been evaluated in detail based on current studies. The finding that the interaction between salinity and microplastics creates synergistic stress and can increase yield loss, particularly in agricultural production, is an important component of the review. In conclusion, it is understood that the effects of microplastics on plant health, soil functions, and food safety will play a decisive role in shaping future agriculture–environment policies.

Keywords: Microplastics, soil ecology, plant ecophysiology, polystyrene, salinity stress, environmental risk.

Abstract

In many filtration systems, the accumulation of contaminants on membrane surfaces significantly restricts both permeation and separation efficiency, highlighting the necessity for advanced functional materials. Consequently, research efforts increasingly focus on the development of highly efficient, durable, and cost-effective polymeric composite membranes. In this study, bio-oil—an organic mixture enriched with phenolic binders and produced through the controlled pyrolysis of carbon-based materials—was incorporated into cellulose acetate membranes for the first time by blending it into a 15% CellA solution in DMAC to enhance membrane performance. CellA-based biocomposite membranes containing 5%, 10%, 20%, and 40% bio-oil were fabricated via phase inversion in a water bath, resulting in micro-size composite structures. The crystalline features, molecular interactions, and surface morphologies of the membranes were investigated using FT-IR and SEM analyses. Additionally, water uptake values were determined to assess hydrophilicity. The adsorption performance of the composites was evaluated in batch mode using 0.1–1 g of material in 5–80 ppm methylene blue solutions. The effects of temperature, adsorbent dosage, dye concentration, and pH on removal efficiency were systematically examined. Increasing bio-oil content was found to alter the membrane morphology and significantly improve adsorption-driven dye removal. Temperature was observed to have no substantial effect on adsorption efficiency, whereas the optimal adsorbent dosage was identified as 0.5 g. Under these optimized conditions, dye removal efficiencies ranging from 60% to 90% were achieved depending on the composite formulation. Overall, the successful fabrication and characterization of these micro-sized CellA/bio-oil composites demonstrate their strong potential as sustainable and high-performance filtration materials, offering improved foulant interaction and enhanced adsorption capabilities compared to conventional cellulose acetate membranes.

Keywords: Cellulose acetate, Bio-oil, Composite membranes, Methylene blue

Abstract

Selenium is an essential trace element involved in antioxidant defense and numerous physiological processes [1]. Selenium nanoparticles (SeNPs) have gained increasing attention due to their enhanced bioactivity, improved biocompatibility, and generally lower toxicity compared to bulk selenium [2]. Biogenic SeNPs, typically capped and stabilized by proteins, polysaccharides, and phenolic compounds, often display superior colloidal stability and biological performance relative to chemically synthesized nanoparticles [3,4]. In this study, SeNPs were synthesized via an eco-friendly method using an ethanolic extract of the cyanobacterium *Leptolyngbya* sp., and their physicochemical properties and biological activity were evaluated. UV–Vis spectroscopy confirmed nanoparticle formation, revealing a characteristic absorption band at 265–285 nm. FTIR analysis revealed the presence of biomolecules responsible for reducing and stabilizing selenium ions. SEM imaging revealed the formation of predominantly rod-like, aggregated structures ranging from nanometer- to lower micrometer-scale assemblies. The synthesized SeNPs exhibited potent antibacterial activity against *Staphylococcus aureus* ATCC 25923, while showing moderate or limited effects on *Escherichia coli* ATCC 25922 and *Candida albicans* ATCC 10231. Additionally, the nanoparticles demonstrated notable antioxidant capacity, likely due to bioactive capping agents provided by *Leptolyngbya* sp., which have been reported to enhance biological functionality in biogenic nanomaterials [3]. Overall, *Leptolyngbya* sp. proved to be a promising and sustainable biological platform for the green synthesis of SeNPs. The resulting nanoparticles, exhibiting potent antioxidant and selective antibacterial properties, represent promising candidates for future biomedical and agricultural applications.

Abstract

Polymeric membrane materials are still the most preferred structures for water filtration and purification due to their affordability and ease of preparation. However, numerous studies are ongoing to improve their physical and chemical resistance and performance. Efficiency can be increased by adjusting the structure's durability and porosity with organic and inorganic additives. In this study, bio-oil, a biomass carbonization product, was first added to cellulose acetate by mixing it with a 15% CA solution in DMAC. To prepare the composites, the polymer solutions were spread on a glass surface using a 250-micron casting knife, and the films were then placed in a water bath for phase inversion, resulting in flat-sheet CA/bio-oil composites containing 5%, 10%, 20%, and 40% bio-oil. The structural properties and surface features of the materials were analyzed using FT-IR and SEM. Water uptake and porosity% values were also measured to understand changes in hydrophilicity. Adsorption experiments were carried out in batch mode using 0.1–0,75 g of composite cut 1*1 cm in methylene blue solutions ranging from 10-80 ppm. The effects of temperature, adsorbent amount, solution concentration, and pH on dye removal were also studied. Higher bio-oil content changed the surface structure of the composites and improved their ability to remove dye through adsorption. The best adsorption efficiency was achieved at room temperature, while the optimal adsorbent amount was found to be 0.5 g in batch conditions. Under these optimum conditions, the composites achieved dye removal values of 40-85%, varying with the change in bio-oil ratio. Overall, the flat-sheet CellA/bio-oil composites are promising materials for continuous filtration systems, and their performance can be tested and potentially used as membrane structures.

Abstract

Alzheimer's disease (AD) is a progressive neurodegenerative disorder that affects cognitive functions worldwide, leading to memory impairment and behavioral changes. Although currently available medications provide symptomatic relief, they are ineffective at preventing disease progression. The pathogenesis of AD involves multiple mechanisms, including amyloid-β (Aβ) plaque accumulation, hyperphosphorylation of tau proteins, oxidative stress, and cholinergic dysfunction [1]. Among these, the cholinergic hypothesis, which proposes that reduced levels of acetylcholine (ACh) in the brain are a major contributor to AD symptoms, remains one of the most widely accepted models for therapeutic intervention. In recent years, efforts toward the development of multi-target-directed ligands (MTDLs) that combine acetylcholinesterase (AChE) inhibition with additional neuroprotective properties, such as antioxidant and anti-inflammatory activities, have significantly increased [2]. In this context, hybrid molecules that integrate distinct pharmacophores into a single scaffold have emerged as promising therapeutic candidates. Phenolic compounds such as caffeic, vanillic, and ferulic acids attract particular interest due to their well-documented antioxidant activities and favorable safety profiles [3-4]. In the present study, a series of hybrid molecules was designed and synthesized by combining the *N*-benzylpiperidine pharmacophore of Donepezil, an established AChE inhibitor, with phenolic acids possessing antioxidant characteristics. The antioxidant capacities of the compounds were evaluated using DPPH radical scavenging and ferric reducing power assays, identifying isovanillic acid-*N*-benzylpiperidine as the molecule with the strongest antioxidant activity (Fig. 1). Based on these findings, future studies will focus on expanding the biological evaluation of these novel hybrid molecules, including butyrylcholinesterase (BuChE) selectivity and cell-based assays to better explain their therapeutic potential in targeting both AChE inhibition and oxidative stress in AD.

Synthesis of the various macro initiator for production of the blok/graft copolymers via "living"/controlled radical polymerization (CRP) techniques

Melahat Göktaş

Van Yüzüncü Yıl University, Faculty of Education, Department of Chemistry, Van, 65080 Turkey

Corresponding author: e-mail: melahat_36@hotmail.com

Abstract

Recently, the production of block/graft copolymers with controlle molecular weight and low dispersity has increased with the emergence of controlled radical polymerization (CRP) techniques such as reversible addition/fragmentation chain transfer (RAFT) [1], atom transfer radical polymerization (ATRP) [2], nitroxide-mediated polymerization (NMP) [3], which are based on radical polymerization and radical closure mechanism. In here, the various block/graft copoymers was obtained using macro initiator by CRP. These macro initiator which having active centers was synthesized via condensation, ring-opening, and redox polymerizations of the various monomers. Thanks to these active centers, copolymers were obtained by polymerizing various monomers with either ATRP or RAFT polymerization using these initiators. The novel macromolecules could be obtained by combining different monomers in the same polymer chain with both these active-center macroinitiators and CRP techniques. By combining such different polymerization techniques, block/graft copolymer synthesis in one step or through different steps could make a great contribution to polymer chemistry and polymer technology.

Keywords: Macro initiator; block/graft copolymers; condensation polymerization; ring- opening polymerization; redox polymerization.

Abstract

Nanoparticles (NPs) fabricated from inorganic/organic compounds are nano-scale structures with high porosity and numerous active sites with high binding capacity on their surfaces. Thanks to these properties, NPs are utilized in many research fields. The conservation of cultural heritage is an important field of research that offers opportunities for the use of nanoparticles in preservation of the originality of constructions and artifacts that have a place in the historical development of humanity. Over time, the chemical or physical resistance and structural integrity of artifacts such as metal, paper, wood, and stone are constantly threatened by degradation factors depending on environmental conditions. Hence, the need for innovative materials such as NPs, which can penetrate deep into damaged artifacts due to their particle size, has emerged in the field of conservation and restoration. Since it has been reported that paper-based artifacts become deteriorated over time due to factors such as moisture, oxidation, acid degradation, bacteria, and fungi, nanotechnology applications may provide a good alternative for direct and effective protection against the deterioration of paper-based artifacts. In this presentation, the experimental studies on the NPs synthesized for the conservation of some paper-based historical artifacts and their application/effect mechanisms have been evaluated.

Özet

Alzheimer hastalığı (AH) çoğunlukla yaşlı insanları etkileyen nörodejeneratif bir hastalıktır. Bu hastalık hafıza kaybı, ruh hali bozuklukları, depresyon ve bilişsel yeteneklerin ilerleyici kaybı ile karakterize edilmektedir [1]. Alzheimer hastalığının kökenini açıklamak için tau protein hiperfosforilasyonu, beta-amiloid agregasyonu ve kolinerjik hipotez gibi bazı teoriler öne sürülmüştür [2]. Bu teoriler arasında kolinerjik hipotez, nörotransmitter asetilkolin (ACh) seviyelerinin azalmasının AH'nin nedeni olduğu ve beyindeki ACh seviyelerinin artmasının AH tedavisi için hayati önem taşıdığını öne süren ve en yaygın kabul gören teoridir [3]. Asetilkolinesteraz (AChE), kolinesteraz ailesinden bir enzimdir. AChE, ACh'nin hızlı hidrolizini katalize ederek ACh seviyelerini düşürür ve kolinerjik sinapslarda impuls iletiminin sonlandırılmasına neden olur. Kolinerjik hipoteze göre AChE enziminin inhibisyonu azalan ACh seviyelerini düzenleyerek Alzheimer hastalığının tedavisinde etkili olmaktadır [4]. Bu çalışmada Guo ve çalışma arkadaşları tarafından *Broussonetia papyrifera* bitkisinden izole edilip literature yeni kazandırılan beş 1,3-difenilpropan türevi doğal molekülün [5] AChE enzimi ile etkileşimleri moleküler kenetleme yöntemi kullanılarak incelendi ve standart ilaç Donepezil ile karşılaştırıldı. Moleküler kenetleme yöntemi sonuçlarına göre standart ilaç Donepezil -10,92 kcal/mol bağlanma serbest enerjisi ile AChE aktif bölgesi ile etkileşti. 1,3-difenilpropan türevleri ise -9,92 ila -11,08 kcal/mol bağlanma serbest enerjileri ile AChE aktif bölgesi ile etkileşim gösterdi. Bu sonuçlar bu doğal ürünlerin Alzheimer tedavisinde kullanılması için umut verici olduğunu gösterdi.

Abstract

The Lamiaceae family is one of the richest families, containing over 7,000 species. It is distributed in various environmental conditions across different regions of Turkey. Members of this family are also of considerable importance for medicinal use. This study compiles information on the pharmacological properties of selected species belonging to the family, the level of antimicrobial activity of these species, and the diseases they combat.

Abstract

Melanin is a natural biological pigment that plays a fundamental role in the pigmentation process of the human body. It contributes to the pigmentation of various tissues, including the skin, hair, and eyes, and protects the skin against the harmful effects of ultraviolet radiation. However, excessive melanin production and accumulation can lead to several dermatological disorders, such as freckles, pigmented acne, melasma, and age spots, and may even increase the risk of malignant melanoma [1]. Tyrosinase is a key enzyme in melanin biosynthesis. Inhibition of tyrosinase is considered an effective strategy to reduce melanogenesis and control abnormal melanin accumulation. Tyrosinase inhibitors are used as skin-whitening agents and antimelanogenic compounds, as well as in melanoma treatment. Hydroquinone, arbutin, tretinoin, kojic acid, azelaic acid, and ascorbic acid are examples of synthetic and natural tyrosinase inhibitors. However, their side effects, including leukoderma, cytotoxicity, dermatitis, and skin irritation, limit their clinical use. Therefore, the design and discovery of new tyrosinase inhibitors with lower toxicity and higher skin permeability are of great importance in treating skin hyperpigmentation [2]. The 1-(4-fluorobenzyl)piperazine scaffold has emerged as an important structural motif that significantly enhances the biological activity of synthetic tyrosinase inhibitors [3]. Dithiocarbamate also represent a prominent scaffold in drug discovery, with several compounds reported to exhibit tyrosinase inhibition activity [4]. In this study, a series of novel 1-(4-fluorobenzyl)piperazine-based dithiocarbamate acetamides were synthesized and evaluated for their in vitro tyrosinase inhibition activity, using kojic acid as the standard. Among all the target molecules, the compound bearing the 2-nitrophenyl exhibited the highest activity, showing 76% inhibition of the tyrosinase enzyme.

Abstract

MicroRNAs (miRNAs) are short non-coding RNA molecules that regulate gene expression and contribute to many essential biological processes in eukaryotic organisms. In addition to endogenous miRNAs, several dietary-origin miRNAs encoded by non-host genomes have been detected in human circulation and are described as xenomiRNAs (XenomiRs). Growing evidence suggests that XenomiRs can enter mammalian systems through food consumption and may modulate the expression of target genes. Despite the widespread consumption of chicken eggs, the effect of thermal processing on the stability of egg-derived miRNAs remains insufficiently characterized. Eggs form a complex biological matrix rich in proteins and regulatory molecules associated with embryonic development; therefore, determining how cooking influences the preservation of miRNA is of particular interest for both molecular biology and functional nutrition. This study investigated the impact of heat treatment on the expression of three miRNAs (gga-miR-30c-5p, gga-miR-191-5p, and gga-miR-215-5p), which show high sequence homology between humans and chickens and have been implicated in various diseases. Twenty Lohman Brown and twenty Leghorn eggs were separated into raw and boiled groups and pooled into eight sample sets. Total RNA was isolated using a commercial kit, and cDNA synthesis was performed with the miRCURY RT kit. miRNA expression levels were quantified by RT-qPCR and normalized using the exogenous cel-miR-39 spike-in control. The results revealed a marked reduction in miR-30c-5p levels following thermal processing, with significant decreases observed in both brown and white eggs ($p < 0.05$). miR-191-5p showed moderate but statistically significant reductions between raw and cooked samples. miR-215-5p expression decreased significantly in brown eggs while remaining relatively stable in white eggs. These findings suggest that miRNA heat sensitivity is molecule-specific and that miR-30c-5p is particularly susceptible to thermal degradation. Overall, the study offers essential preliminary data for future nutrigenomic and functional food research examining the stability and biological relevance of egg-derived miRNAs.

Abstract

In recent years, the increasing interest in sustainable biomaterials has encouraged the reuse of biological waste and the development of hydrogel systems for tissue engineering applications. This study aimed to prepare a collagen/keratin/alginate (C/K/A) hydrogel system and optimize the total RNA isolation procedure from human osteosarcoma cells (Saos-2) cultured within that system. Collagen was extracted from bovine *Achilles* tendon via enzymatic hydrolysis, while keratin was isolated from waste human hair using a reduction-based method. Both extracted proteins exhibited their characteristic FTIR bands. SDS-PAGE analysis confirmed the presence of γ- and β-collagen bands along with α1(III), α1(I), and α2(I) chains for extracted collagen, and α- and β-keratin bands in extracted keratin. Hydrogels were prepared at a 1:1:1 C/K/A weight-to-volume ratio and crosslinked with calcium chloride and EDC/NHS. C/K/A hydrogels showed a porous internal architecture and a high water retention capacity of approximately 984%. The characteristic peaks of all three components of hydrogels were observed in FTIR analysis. Degradation studies indicated that 57% of the hydrogel mass remained intact after 21 days, demonstrating suitable structural stability for cell culture application. Saos-2 cells cultured within the three-dimensional hydrogel system maintained viability for up to 7 days, indicating the suitability of the three-dimensional hydrogel system compared to the traditional two-dimensional culture system. Total RNA isolation from the cell-seeded hydrogels was successfully achieved using an optimized protocol. RNA quality was confirmed by RT-PCR, where clear GAPDH bands were obtained.

Synthesis and characterization of biodegradable polyester by ring-opening polymerization (ROP)

Melahat Göktaş

Van Yüzüncü Yıl University, Faculty of Education, Department of Chemistry, Van, 65080 Turkey

Corresponding author e-mail: melahat_36@hotmail.com

Abstract

The Ring-opening polymerization (ROP), like radical polymerization, occurs by the addition of monomer molecules to the chain. Ring-opening polymerization generally follows an anionic or cationic mechanism, and many lactones are polymerized by ROP [1]. The Cyclic lactones such as *β*-butyrolactone (BL) and ε-caprolactone (CL) are cyclic monomers that could be polymerized by ring-opening polymerization [2,3]. In this study, biodegradable polyethylene glycol-based (PEG) block copolymer polyesters were synthesized and evaluated via the ring- opening polymerization (ROP) method. For this purpose, biodegradable poly(ethylene glycol- *b*-ε-caprolactone) [PEG-*b*-PCL] block copolymer polyesters were synthesized by ring-opening polymerization of ε-caprolactone (CL) in the presence of polyethylene glycol (PEG) initiator. This polymerization was carried out both as dispersion and bulk polymerization and the effect of the solvent on the molecular weight of the synthesized polymer was investigated. The products were characterized by spectroscopic methods such as infrared spectroscopy (FTIR), proton nuclear magnetic resonance spectroscopy (^{1}H-NMR), and gel permeation chromatography (GPC).

Keywords: biodegradable polyester; block copolymers; ring-opening polymerization.

Özet

Nüfus artışı, kentleşme ve sanayileşme ile birlikte, üretilen atıksu miktarı artmakta ve atık su özellikleri değişmektedir. Bu durum atıksu arıtma tesislerinin çevresel sürdürülebilirlik açısından önem kazanmasına neden olmuştur. Atıksu arıtma tesisleri, atıksuların doğaya zarar vermeyecek düzeyde arıtılmasını sağlarken, enerji kullanımı, kimyasal tüketimi ve arıtma sürecinde ortaya çıkan sera gazları nedeniyle karbon ayak izine neden olur. Bu sebeple, atıksu arıtma tesislerinin karbon ayak izlerinin tespit edilmesi ve yönetilmesi, sürdürülebilir bir yönetim stratejisi açısından büyük önem arz etmektedir. Bu çalışmada, atıksu arıtma tesislerinde karbon ayak izine neden olan unsurlar ve karbon ayak izi azaltım stratejileri değerlendirilmektedir. Bu kapsamda konu ile ilgili uluslararası ve ulusal literatürde yer alan çalışmalar özetlenmiş ve atıksu arıtma tesislerinin enerji tüketimi ve sera gazı salınımı üzerindeki etkileri incelenmiştir. Genel olarak elde edilen sonuçlar, atıksu arıtma tesislerinde karbon ayak izi yönetiminin hem çevresel sürdürülebilirlik hem de iklim hedefleri açısından önemini yansıtmıştır

Anahtar Kelimeler: Atıksu arıtma, karbon ayakizi

Abstract

Enterobacter cloacae is a clinically significant opportunistic pathogen responsible for nosocomial infections, particularly in mechanically ventilated patients in intensive care units. Its ability to form biofilms and secrete various cytotoxins plays an important role in its pathogenicity. *Vincetoxicum hirundinaria* Medik. (Apocynaceae: Asclepiadoideae), commonly known as white swallow-wort, has numerous documented medicinal uses in various countries. In Turkey, it is known as "kırlangıç kuyruğu, kuş gavurbiberi, and panzehir otu" and the roots have been documented to possess emetic properties. The study aimed to investigate the antibacterial potential of ethanol extracts obtained from different parts (leaf, flower, seed, and seed pod) of *V. hirundinaria* naturally growing in Turkey. Antibacterial activity was evaluated against *Enterobacter cloacae* ATCC 23355 using disk diffusion and Minimum Inhibitory Concentration (MIC) assays. Gentamycin was used as the standard antibiotic control. Extract concentrations ranged from 0.1 g/mL to 0.00015259 mg/mL were evaluated. Disk diffusion tests revealed measurable inhibition zones for all extracts. MIC values against *E. cloacae* ranged from 1.5625 to 3.125 mg/mL. Among all extracts, the ethanol extract of the seeds demonstrated the strongest antibacterial effect against *E. cloacae*. Overall, the findings indicate that different parts of *V. hirundinaria* possess antibacterial potential against *E. cloacae*, a Gram-negative bacterium.

Abstract

The mixture of hundreds of pollen grains that honey bees gather and wet with a small amount of nectar and saliva secretion is known as honey bee pollen. It is acknowledged that either fresh or dried honey bee pollen works well as a nutritional supplement and food additive. For this reason, bee pollen has been widely researched in recent years in terms of its antioxidant activity and content, and its effects on health have also been discussed. The aim of this research was to determine the DPPH scavenge activity of bee pollen, collected from a beekeeper in Kızılcahamam/Ankara. The bee pollen was extracted in three different solvents containing 15% of 0.1 N acid (methanol:0.1 N HCl; ethanol:0.1 N HCl; distilled water: 0.1 N cytric acid (v/v: 85/15)) and the DPPH scavenge activity was measured using the gallic acid as standard. The results were measured as 1.46±0.01 mg/g GAE in methanolic, 1.42±0.03 mg/g GAE in ethanolic and 0.65±0.04 mg/g GAE in aqueous extracts. The inhibition percentage for each solution on the given concentration was found 90.87±0.24% in methanol, 89.97±0.82% in ethanol and 55.27±2.25% in aqueous extracts. According to the results it was found that the methanolic and ethanolic extract showed a higher antioxidant activity than the aqeous extraction. Because they alter the kind and quantity of phenolic compounds dissolved in the extract, the polarity differences of the extraction solvents have a direct impact on the DPPH radical scavenging activity. Additionally, by promoting the release of phenolic compounds from plant tissue and boosting their stability at low pH, the addition of acid improves the extraction efficiency. The differences in studies can be due to a number of biological and chemical factors. Since floral species range significantly in their total antioxidant activity, the pollen's botanical origin is a major determinant.

Abstract

Olive (*Olea europaea*), one of the most fundamental species in Mediterranean agriculture, is a critical biological component of sustainable production thanks to its high adaptability to environmental factors and the bacterial and fungal communities it hosts around its roots. However, limited information is available regarding the factors shaping the structure of the olive rhizosphere microbiota and the functional contributions of this ecological unit. In this study, soil samples collected from the olive rhizosphere in the Kahramanmaras region were analyzed using high-throughput amplicon sequencing targeting the 16S rRNA V4 region. Taxonomic separation was performed at the ASV level using QIIME2. Microbial diversity indices, dominant taxonomic groups, and core microbiota components were examined. The results showed that the olive rhizosphere has a distinctly bacterial-dominated community. The majority of the community was comprised of the phyla Proteobacteria (32–38%), Actinobacteria (24–29%), and Firmicutes (10–15%). These three groups represented more than 70% of the total microbial population, defining the core microbiome. At the species level, Streptomyces (9–12%), Pseudomonas (7–11%), Bacillus (5–8%), and Rhizobium spp. (4–7%) were prominent as the primary bacterial species, occurring in high abundance and repeated across all samples. The study identified Streptomyces, in particular, as a keystone taxon in the ecosystem, with positive co-occurrence relationships. These interactions indicate that functional processes such as nutrient cycling, siderophore production, phosphate solubilization, nitrogen fixation, and pathogen suppression are actively occurring in the rhizosphere. High alpha diversity (Shannon >4.0) supported the rich and balanced structure of the community. This study presents the first detailed metagenomic profile of the olive rhizosphere microbiota in Turkish conditions and demonstrates that the Streptomyces–Pseudomonas–Bacillus axis may be an important microbial resource for biofertilizer development. The findings provide important information for the development of microbiome-based fertilization strategies and sustainable soil management practices in olive cultivation.

Membrane cholesterol modulation Alters P2x7-mediated membrane currents but not cytoskeletal reorganization in macrophages

Abstract

This study examined whether altering membrane fluidity through cholesterol depletion differentially modulates two hallmark functional outcomes of the P2X7 purinergic receptor—ATP-evoked ion channel currents and cytoskeletal reorganization. We specifically asked whether these responses remain coupled or diverge when membrane cholesterol is reduced. RAW 264.7 macrophage-like cells, which endogenously express P2X7, were cultured on glass coverslips and used 24 hours after seeding. Light microscopy was used to assess ATP-induced morphological changes—retraction of cellular extensions, cell rounding, and detachment from the substrate—following ATP stimulation (1 mM, 20 min). The procedure was repeated after decreasing membrane cholesterol using methyl-β-cyclodextrin (MβCD, 5 mM, 40 min). P2X7-mediated ion currents were recorded using the whole-cell patch-clamp technique under symmetrical ionic conditions to prevent driving-force–related artefacts. Measurements were performed under control conditions and after cholesterol depletion. Cholesterol depletion did not alter the characteristic morphological responses triggered by ATP. Cells still exhibited cytoskeletal reorganization, rounding, and partial detachment, indicating that P2X7-linked structural signaling remained intact. In contrast, electrophysiological experiments demonstrated a nearly twofold increase in P2X7-mediated membrane currents after MβCD treatment, with a statistically notable difference ($p < 0.06$). This selective enhancement suggests that reduced cholesterol amplifies the receptor's ion channel function while leaving cytoskeletal responses unchanged. The dissociation between preserved morphological signaling and enhanced ion channel activity following cholesterol depletion was unexpected. Because P2X7 current amplitude typically correlates with the number of functional receptors at the plasma membrane, the increased current amplitude may reflect greater membrane expression of P2X7 or a higher channel open probability. These findings indicate a potential uncoupling of electrophysiological and structural outputs downstream of P2X7 when membrane composition is altered. Future work examining surface receptor abundance, membrane localization, and lateral diffusion dynamics will be essential to clarify the mechanism underlying the selective potentiation of P2X7-mediated currents under low-cholesterol conditions.

In silico evaluation of potential inhibitors against *Moraxella catarrhalis* 3-oxoacyl-[acyl-carrier-protein] reductase (FabG)

Sinem Kocer (Orcid:https://orcid.org/0000-0003-0517-7422)

Istanbul Yeni Yuzyil University, Faculty of Pharmacy, Department of Pharmaceutical Technology, Istanbul, Türkiye

Corresponding author e-mail: sinem.kocer@yeniyuzyil.edu.tr

Abstract

Moraxella catarrhalis is a Gram-negative bacterium that contributes significantly to childhood otitis media and upper and lower respiratory tract infections in adults. Most clinical isolates produce β-lactamases, conferring resistance to ampicillin, which underscores the urgent need for alternative therapeutic strategies [1-2]. The 3-oxoacyl-[acyl-carrier-protein] reductase (FabG), a key enzyme of the bacterial FAS II pathway, represents a promising drug target due to its essential role in cell membrane biosynthesis and absence in humans [3]. In this study, three FabG inhibitor candidates (PubChem IDs: 71750693, 32036, 132277201) previously identified in the literature [4], along with clavulanic acid and amoxicillin, were evaluated for their inhibitory potential against *M. catarrhalis* FabG (McFabG). The three-dimensional structure of McFabG (UniProt ID: A0A3A9ND81, NCBI Protein ID: AZQ92700) was modeled using Swiss-Model. Structural minimization was performed with 2,000 steps of steepest descent in Chimera 1.13.1, and model reliability was confirmed via ERRAT (overall quality factor: 96.957), Ramachandran plot (90.8% residues in favored regions), and ProSA-web (The Z-score of −8.48 was determined, indicating consistency with experimentally resolved protein structures.). Potential binding pockets were identified using DogSiteScorer, and the pocket with the highest druggability score (0.81) was selected for docking. Molecular docking was conducted using SwissDock with the AutoDock Vina method. Binding affinities of −8.132, −8.061, and −7.516 kcal/mol were observed for compounds 71750693, 32036, and 132277201, respectively. Clavulanic acid and amoxicillin showed binding affinities of −5.819 and −7.833 kcal/mol. Compound 71750693 demonstrated the highest interaction potential with McFabG, while clavulanic acid exhibited the lowest binding, and amoxicillin was identified as a relatively acceptable inhibitor. These results highlight compound 71750693 as a promising McFabG inhibitor candidate. However, the findings are predictive and require further validation through advanced molecular docking and simulation studies.

Abstract

Liver is involved in the detoxification of lipopolysaccharide (LPS), thereby playing an essential physiological role in clearing endotoxin of intestinal derivation from the body. However, there is little information available regarding the LPS-associated histopathological changes in the liver of female mice. Therefore, we analyzed the effects of acute LPS on histopathological changes, mast cell number, and CD45 expression in the murine liver. For this purpose, animals were divided into two groups and received a single intraperitoneal injection of either 100µg LPS or PBS. Liver samples were collected 24h after the LPS injection. In all groups, liver samples were checked for the presence of degenerative changes and the accumulation of inflammatory cells with Haematoxylin&Eosin and Crossman's triple staining. Control mice receiving PBS showed compact and well-organized hepatocytes. However, when mice were treated with 100µg of LPS, hyperemia was observed within the blood vessels of the liver. Therefore, we investigated whether this treatment induce leucocyte infiltration in the mouse liver. To assess this, we examined the expression of CD45 using an immunohistochemistry and mast cell availability with toluidine blue staining. Only weak signals for CD45 were detected within the liver of control mice. However, in LPS-treated mice, CD45-positive cells appeared more widespread and distinctly localized within the blood vessels and sinusoids of the liver. Furthermore, the percentage of CD45-positive immunoreactive area was significantly higher than that of the controls. Only a few mast cells were detected within the liver of control and LPS-treated mice. In conclusion, acute LPS administration in female mice appears to induce leukocyte infiltration in the liver, while it does not affect mast cell numbers. Thus, this model provides valuable insight into the mechanisms of LPS-induced liver inflammation. However, further studies are needed to clarify the long-term effects of LPS exposure on the dynamics of hepatic immune cells.

Özet

Toll-like reseptörler (TLR), Patern Tanıma Reseptörler (PRR) ailesine ait tip I transmembran proteinlerdir. Birçok patojene karşı doğal immün cevabın oluşmasını sağlayan reseptörlerdir. Meyve sineğindeki (Drosophila) 'Toll' genine benzemeleri nedeniyle bu isim verilmiştir. TLR'ler, patojen ilişkili moleküler (PAMP) ve hasar ilişkili moleküler (DAMP) tarafından aktive edilirler. Memelilerde on üç farklı tip TLR tanımlanmıştır. İnsanda en çok araştırılan ve fonksiyonu aydınlatılan TLR4'tür. TLR4, Gram negatiflerin hücre duvarında bulunan lipopolisakkaritin (LPS) tanınmasında rol almaktadır. LPS'nin, TLR4 aracılığıyla tanınmasında üç farklı ekstraselüler protein görev yapmaktadır. Bunlar; LBP, CD14 ve MD-2'dir. LPS, plazmada bulunan LBP tarafından bağlanır. LBP-LPS kompleksi, hücre yüzeyindeki CD14 reseptörüne aktarılır. CD14, LPS'yi TLR4 reseptörüne sunar. LPS, hücre yüzeyinde bir kompleks oluşturan MD-2 ve TLR4'e transfer edilir. TLR4-MD2 kompleksi M şeklinde dimerize olur. Böylelikle MyD88 bağımlı ve MYD88 bağımsız sinyal kaskadları uyarılır. TIR alanı içeren adaptör protein (TIRAP) ve MyD88, MyD88'e bağımlı sinyallemeyi aracılık ederken, TIR alanı içeren adaptör indükleyen interferon beta (TRIF) ve TRIF ile ilişkili adaptör molekül (TRAM), MyD88'den bağımsız sinyallemeyi aracılık eder. MyD88'e bağımlı yol proinflamatuar sitokin ekspresyonunu aktive ederken MyD88'den bağımsız sinyalleme tip I interferon genleri aktive eder. Sonuç olarak, LPS aracılı hücre içi sinyal iletimiyle MyD88 bağımlı ve bağımsız yollar aktive olur; bu durum NF-KB'nin uyarılmasına, proinflamatuvar sitokinlerin (TNF-α, IL-1β, IL-6) yüksek oranda salınımına neden olur ve sistemik inflamatuar yanıt gelişir. TLR4 aracılığıyla aşırı sinyal iletimi meydana gelirse bu durum sistemik inflamasyona, sitokin fırtınasına ve sepsise yol açabilir.

Dose-dependent cytotoxic effect of Carbidopa on U-87 MG human glioblastoma cells

Burak Bircan (Orcid: https://orcid.org/0000-0003-1141-069X)

Osmaniye Korkut Ata University, Health Services Vocational School, Department of Medical Services and Techniques, Osmaniye, Türkiye

Corresponding author e-mail: burakbircan@osmaniye.edu.tr

Abstract

Carbidopa is a peripheral aromatic L-amino acid decarboxylase inhibitor routinely administered in combination with levodopa for the treatment of Parkinson's disease. Although the repurposing of non-oncological drugs for cancer therapy has gained increasing attention, the direct cytotoxic effect of carbidopa on glioblastoma cells remains unclear. In this study, we aimed to evaluate the dose-dependent cytotoxic effect of carbidopa on U-87 MG human glioblastoma cells. Cells were seeded into 96-well plates and, following a 24-hour attachment period, treated with carbidopa at concentrations of 1, 10, 25, 50, 100, and 200 µM. Cell viability was assessed using the MTT assay, and absorbance was measured at 550 nm. Viability was expressed as a percentage relative to untreated controls. IC_{50} and $logIC_{50}$ values were calculated from dose–response curves generated using GraphPad Prism 8. Data were analyzed using the Kruskal–Wallis test, and $p<0.05$ was considered statistically significant. Carbidopa at 1 µM did not significantly affect cell viability (68.56±8.68%) compared with the control (100±8.41%) and vehicle groups (96.87±11.01%). In contrast, significant reductions in viability were observed at concentrations ≥10 µM (59.97±6.65% at 10 µM, 57.74±7.27% at 25 µM, and 41.92±8.20% at 50 µM; $p<0.05$). At 100 and 200 µM, viability decreased to 9.89±1.18% and 10.94±0.40%, respectively ($p<0.05$). The IC_{50} value for U-87 MG cells was determined as 23.36 µM ($logIC_{50} = 1.36$). Carbidopa exhibits a pronounced, dose-dependent cytotoxic effect on U-87 MG glioblastoma cells, with significant decreases in viability beginning at 10 µM and an IC_{50} in the low micromolar range. These findings suggest that carbidopa may represent a promising repurposing candidate for glioblastoma therapy.

Abstract

Numerous studies in the literature have reported on the anticancer activities of hydrazone and urea derivatives. Hydrazones have attracted considerable attention due to their distinctive physical, chemical, and biological properties, and they have been extensively investigated for various therapeutic applications, including antibacterial, anticancer, anti-HIV, anticonvulsant, and antitubercular activities. In medicinal chemistry, compounds bearing the hydrazide–hydrazone scaffold have long been of interest owing to their strong biological potential and their usefulness in the development of new antimicrobial, analgesic, anti-inflammatory, and particularly anticancer agents. In the present study, *N*-(4-hydroxyphenyl)-*N*'-phenylurea (compound 1), derived from p-aminophenol, was reacted with ethyl bromoacetate in acetone in the presence of anhydrous potassium carbonate to afford Ethyl {4-[(phenylcarbamoyl)amino]phenoxy}acetate (compound 2). Treatment of compound 2 with hydrazine hydrate in ethanol yielded *N*-[4-(2-hydrazinyl-2-oxoethoxy)phenyl]-*N*'-phenylurea (compound 3). Subsequent reactions of compound 3 with various substituted benzaldehydes successfully afforded a series of 34 novel diphenylurea derivatives of the target structure, namely *N*-(4-{2-[(2E)-2-benzylidenehydrazin-1-yl]-2-oxoethoxy}phenyl)-*N*'-phenylurea (compound 4-37). The purity of the synthesized compounds was confirmed by elemental analysis and HPLC data, while their structures were elucidated using FT-IR, ^{1}H-NMR, ^{13}C-NMR, and mass spectrometry. Following structural characterization, the cytotoxic potential of the synthesized compounds was initially screened against HDF (Human Dermal Fibroblasts), compouds that were non-toxic was evaluated for their anti-cancer potentials on U-87MG (Human Glioblastoma), MDA-MB-231 (Human Breast Adenocarcinoma), and PC-3 (Human Prostate Adenocarcinoma) cell lines. Cytotoxic effects were exhibited by CA-1, CA-15, and CA-40 only on PC3 cell line. Further analysis showed that these compounds induced cell cycle arrest at the G0/G1 phase and inhibited the migration of PC-3 cells in a time-dependent manner compared to the untreated control.

Abstract

In this study, polyether-ether-ketone (PEEK) was sulfonated with concentrated sulfuric acid to introduce $–SO_3H$ groups, yielding sulfonated PEEK (sPEEK) with a high degree of sulfonation (DS ≈ 71%). Composite membranes containing 10 and 15 wt% sulfonated TiO_2 (s-TiO_2) nanoparticles were fabricated using the solution-casting method and evaluated for direct methanol fuel cell (DMFC) applications. FT-IR spectra displayed OH stretching bands at 3400–3200 cm^{-1} and a peak at 1690 cm^{-1}, confirming successful sulfonation. Proton conductivity measurements between 30 and 60°C showed a temperature-dependent increase for both membranes. Although Ion exchange capacity (IEC) values decreased slightly due to the dilution effect of the inorganic filler, the high DS ensured sufficient proton-conducting sites within the polymer. Comparing the sPEEK-sTiO_2 (10%) and sPEEK-sTiO_2 (15%) membranes revealed that higher filler loading enhanced the hydrophilicity of the polymer matrix. Water uptake increased from 36.17% to 40.45%, attributed to the hydrophilic $–SO_3H$ groups on s-TiO_2 surfaces. Despite the increase in water uptake, swelling decreased from 59.23% to 47.95%, indicating that the higher inorganic content restricted polymer chain mobility and provided structural stabilization against excessive expansion. Proton conductivity values ranged from 17.38–37.45×10^{-3} S/cm for the 10% sample and 36.54–86.63×10^{-3} S/cm for the 15% sample, suggesting improved ion-transport pathways at higher filler levels. Methanol permeability values for both composites were significantly lower than that of Nafion 117, with the 15% membrane exhibiting a 75% reduction. Consequently, selectivity that is the ratio of ionic conductivity over methanol permeability (σ/P) reached 6.61×10^4 S·cm^{-3}·s, approximately three times higher than Nafion 117. Overall, the results indicate that highly sulfonated sPEEK membranes containing increased s-TiO_2 content offer enhanced methanol barrier performance and competitive proton conductivity, making them strong candidates for DMFC electrolytes and potentially applicable to hydrogen-fed PEMFC systems with further optimization.

Eskişehir Technical University, Faculty of Engineering, Department of Chemical Enginering, Eskişehir, Türkiye.

Corresponding author e-mail: murattamer@eskisehir.edu.tr

Abstract

In this study, the PEEK polymer was modified through a sulfonation process to introduce $–SO_3H$ functional groups onto the polymer backbone, resulting in ion-conductive sPEEK. According to the literature, sPEEK membranes with high degrees of sulfonation (DS% > 60) tend to exhibit excessive swelling and partial dissolution in methanol–water mixtures and therefore are not preferred for direct methanol fuel cell applications. This study, however, focuses on hydrogen-fed PEMFC conditions, evaluating sPEEK with a sulfonation degree of approximately 71%. In this way, the conductivity advantage associated with high DS values can be utilized while maintaining the structural integrity of the membrane under PEMFC operating conditions. To improve membrane performance, the sPEEK structure was transformed into a composite by incorporating an inorganic filler. Among heteropoly acids known to enhance proton conductivity, silicotungstic acid (SiWA) was selected as the active component and immobilized onto a silica matrix via a sol–gel process using TEOS as the precursor. This approach aims to increase the stability of SiWA within the polymer structure. Different SiWA loading levels were verified by FT-IR and XRD analyses. The water uptake behaviour, dimensional stability, and ionic conductivity (within the 30–80 °C temperature range) of the prepared composite membranes were systematically examined. Additionally, the electrochemical performance of the membranes was evaluated in hydrogen-fed PEMFC tests and compared with the Nafion 212 reference membrane. The results demonstrate that sPEEK/SiWA supported on silica exhibits suitable electrochemical and structural properties for PEM fuel cell applications. In addition, the presence of the silica-supported SiWA phase is expected to improve membrane hydration at reduced relative humidity levels by retaining water within the polymer structure.

Abstract

H. pylori infection remains a significant global health issue due to increasing antibiotic resistance and the limited efficacy of current treatments. Nanoparticle-based drug delivery systems offer a novel approach to enhance drug stability, improve mucus penetration, and provide sustained release in the gastric mucosa. In this study, a juglone-silver (J-Ag) dual complex was synthesised and encapsulated into poly(lactic-co-glycolic acid) (PLGA) nanoparticles using a single emulsion-solvent evaporation method. To increase the retention time in the stomach and obtain mucoadhesive properties, it was coated with Eudragit RS100 and a final formulation was prepared. The synthesised juglone-silver (J–Ag) complex and formulations of J-Ag encapsulated within PLGA nanoparticles were characterised using various techniques. Fourier transform infrared spectroscopy (FTIR) analyses were performed to verify the chemical structure of the J-Ag, while MALDI-TOF mass spectrometry was used to determine its molecular weight. The MALDI-TOF analysis confirmed the successful synthesis of the J-Ag, with a synthesis yield of 73%. The size distribution and polydispersity index (PDI) of the nanoparticles were characterised using the dynamic light scattering (DLS) method, while the surface charge of both the synthesised nanoparticles and the structure formed after coating with Eudragit RS100 was evaluated by zeta potential measurements. The shift of the zeta potential value from negative to distinctly positive values after Eudragit RS100 coating indicates that the coating was successful. FTIR results also confirmed that the J–Ag was effectively encapsulated within the PLGA matrix and that the nanoparticle surface was coated with Eudragit RS100 polymer. Scanning electron microscopy (SEM) analyses were performed to examine the morphology of the nanoparticles, and SEM images showed that the particles had a spherical morphology close to the sizes determined by DLS. UV–Vis spectroscopy was used for the characterisation of the complex and its release profile. *In vitro* release studies revealed that the J–Ag exhibited a two-stage release behaviour: an initial rapid release phase was observed, followed by a slower and sustained release profile. This controlled release behaviour indicates that the developed nanoformulation could be a potential candidate for *H. pylori* treatment. It is planned that the therapeutic efficacy of these formulations against *H. pylori* will be evaluated in detail in future studies using in vitro and in vivo models.

Abstract

Gastric cancer is the fifth most common cancer worldwide and the third leading cause of cancer-related mortality. Its known etiology includes Helicobacter pylori infection, obesity, smoking, alcohol consumption, peptic ulcer disease, and gastroesophageal reflux disease. The most used treatment modalities are radiotherapy, chemotherapy, and targeted therapy. However, increasing antibiotic resistance, insufficient early diagnosis, chemotherapy-related toxicities, and the limited availability of targeted agents restrict treatment efficacy. Therefore, new therapeutic strategies are urgently needed. In this study, a CAPE–Ag complex containing the CAPE molecule—previously reported to possess anticancer activity—and Ag was synthesized, encapsulated into PLGA nanoparticles, and subsequently coated with the mucoadhesive Eudragit polymer. The CAPE–Ag complex was characterized by MALDI-TOF analysis, which confirmed the successful formation of the characteristic peak at m/z 391. PLGA nanoparticles loaded with the CAPE–Ag complex (CAPE-Ag@PLGA NPs) were characterized in terms of particle size, zeta potential, polydispersity index (PDI), morphology, reaction yield, and release properties using Zeta Sizer, Scanning Electron Microscopy (SEM), Fourier Transform Infrared Spectroscopy (FT-IR), and UV spectrophotometry. The results demonstrated that CAPE-Ag@PLGA NPs possess suitable particle size, distribution characteristics, and spherical morphology for improved targeting and bioavailability. After coating the nanoparticles with the Eudragit polymer (CAPE-Ag@E-PLGA), the characterization results confirmed that Eudragit was successfully coated onto the surface of the PLGA nanoparticles. In conclusion, Eudragit-coated PLGA nanoparticles encapsulating the CAPE–Ag complex show high potential in terms of efficacy and biocompatibility for the treatment of *Helicobacter pylori*–mediated gastric cancer. Further in vitro anticancer studies are ongoing to evaluate the full therapeutic potential of the developed nanoparticle system.

Abstract

Helicobacter pylori, a microaerophilic bacteria, can colonise the stomach mucosa by adapting to the acidic environment. Approximately half of the world's population is infected with *H. pylori*. *H. pylori* infection treatment involves multiple drug regimens consisting of at least two antibiotics, such as amoxicillin, clarithromycin, and metronidazole, and a proton pump inhibitor (PPI), either with or without bismuth. Schulz et al., in their report covering 31 countries, stated that clarithromycin (24/31) and levofloxacin (18/31) resistance rates were above 15 % in most countries, and that metronidazole resistance was also high in many regions. Furthermore, although amoxicillin resistance was generally low, it was reported to reach remarkably high rates of 70–97 per cent in some African countries. This situation has highlighted the necessity of developing alternative treatment strategies. In this study, PLGA nanoparticles (NPs) encapsulated with juglone-Cu complexes and functionalized with eudragit polymer were prepared to provide a more controlled and targeted antimicrobial effect against *H. pylori* and were characterized by measuring their size and zeta potential using ZetaSizer, imaging with Scanning Electron Microscope (SEM), using Fourier Transform Infrared Spectroscopy (FT-IR) to determine encapsulation efficiency, and release analysis using UV spectrophotometer. Juglone-Cu complexes with a molar ratio of 2:1 (Juglone:Cu) were obtained in high yield compared to other synthesized complexes. The peak at 254.44 m/z in the MALDI-TOF-MS analysis spectrum indicates the hydrated form of the juglone-copper complex for determining the molecular mass of the juglone-Cu complex. Analysis performed using ZetaSizer demonstrated that the Juglone-Cu complexes encapsulated PLGA (J-Cu@PLGA) NPs and Juglone-Cu loaded Eudragit coated PLGA (J-Cu@E-PLGA) nanoparticles are spherical in structure, with average diameters of 262.3 nm and 369.2 nm, respectively. The increase in size of the nanoparticles coated with Eudragit indicates that Eudragit was successfully coated onto the surface of PLGA nanoparticles. These promising results have demonstrated the potential of nanoparticulate complex as effective vehicles for the delivery of antimicrobial agents in the mucosa. In the future, the antimicrobial efficacy of this complex against *H. pylori* can be investigated *in vitro* and *in vivo*.

Abstract

The blue economy, similar to the green economy, aims to promote the efficient use of natural resources and to harness the opportunities provided by nature. It refers to activities that strengthen the relationship between humans and the sea, while also aiming to align transformational production methods with sustainable practices. The blue economy integrates commercial activities, research processes, and technological innovations based on marine resources into a holistic framework. Developing this field sustainably requires effectively mobilizing scientific knowledge and innovation capacity to generate novel solutions that protect marine ecosystems. Marine ecosystems, which are vital for global welfare and economic development, are rapidly deteriorating due to unsustainable resource use, increasing pollution, and the impacts of climate change. In response, marine-based industries are adopting innovative sustainable production models inspired by biorefinery approaches, which aim to convert low-value biomass into economically valuable products while efficiently utilizing waste. A wide range of marine waste is generated both from the processing of seafood products and from dead organisms washing up on shores. This category includes various seafood processing waste, shells accumulated along coastlines, and deceased aquatic plants. The sustainable utilisation of biological materials among marine waste holds the potential to generate economic gains while reducing environmental burdens. These materials are being converted into high-value products using biorefinery technologies, green chemistry, and innovative R&D methods. As a result, waste management is being improved, providing sustainable raw materials for sectors such as food, biotechnology, cosmetics, and agriculture. In this context, the integration of green chemistry and blue economy principles into marine-based sectors is being addressed for a sustainable and profitable marine economy.

Abstract

Beekeeping produces a wide variety of products. In addition to honey, pollen, bee bread, propolis, and royal jelly, which are consumed as nutritional and natural supplements for human and animal health, it is also possible to utilize dead bees after the natural death of the honeybee. This product, called "apis totale" (podmore), is prepared from dead bees collected from hives in the fall or spring. Apis totale (podmore) is prepared from dead bees collected from hives, which naturally contain honey, bee bread, propolis, pollen, royal jelly, apilarnil, bee venom, wax, hormones, and vitamins. Apis totale extract form traditionally uses apitherapy for wound treatment, radiation protection, nerve healing, obesity and general support. In the study we aimed to compare podmore extract with propolis extract and silver sulfadiazine in the treatment of surgically sterilized wounds on the back skin of rats. Chemical analysis, amino acid analysis, wound healing and antioxidant activity level of podmore extract were performed. As a result, it was revealed that podmore extract had positive effects on wound healing in rat back skin. When histopathologic findings were examined, it was observed that podmore and propolis groups were more effective than silver sulfadiazine and had similar appearance. It was found that epithelial integrity was successfully completed in the podmore group, however, in the propolis group, protection in terms of hair follicles and sebaceous glands was at the highest level. Among the experimental groups, the lowest healing was found in the control group and the epidermis thickness was thinner than all groups. Additionally we expect that in an uncompleted study, podmore extract may have a protective effect against the harmful effects of radiotherapy. In radiation-induced dermatitis rat model the healing level of the abdominal skin could follow and dermatitis healing levels, ALT, AST, BUN levels in blood could perform. The protective effects of podmore extract can also be investigated in animal studies if it is used orally before radiation is applied. Our studies are pioneering studies for podmore extract content analysis and its animal studies.

Abstract

Drought and salinity are major abiotic stresses that significantly limit plant growth and productivity. These stresses are increasing in severity their arable lands, particularly in areas with low rainfall and high evaporation, due to the effects of climate change. Sustainable agriculture, breeding and molecular approaches are essential to develop crop varieties tolerant to abiotic stresses. Comparative transcriptomic analyses provide valuable information about the mechanisms associated with stress response. This study used RNA-seq data generated from the SM1 and SM3-1 mutants, developed from the original soybean variety S04-05 by gamma irradiation. Drought and salinity tolerant mutants, were evaluated to identify transcriptional changes and single nucleotide variations (SNPs) associated with stress tolerance. Read quality was assessed with FASTQC (v0.12.1) and low-quality reads were removed with Trimmomatic (v0.40). High-quality reads were aligned to the soybean Williams 82 reference genome (Wm82 v2.a1) using the STAR tool. SNP calling was performed using GATK (v4.6.2.0). 22,549 SNPs in S04-05, 32,105 in SM1, and 27,273 in SM3-1 were identified. Comparative analyses identified 10,070 SNPs specific to SM1, 6,418 specific to SM3-1, and 12,071 common to both mutants. Unique SNPs across mutants were annotated using Ensembl Variant Effect Predictor (VEP). These SNPs were found to affect 13,534 genes in SM1 and 12,472 genes in SM3-1. The 12,071 common SNPs affected 7,347 genes in both mutants. Comparative SNP analysis revealed distinct clusters of variants in SM1 and SM3-1, particularly in genes involved in abiotic stress perception, energy metabolism, and signaling. Genes located in these enriched pathways showed both increased SNP density and significant expression changes. This study provides a comprehensive perspective by examining the relationship between SNP analyses based on RNA-seq data and observed stress tolerance in mutants. The results demonstrate that accumulated point mutations in the genome can lead to diverse, potentially biologically meaningful alterations of stress-related pathways.

Abstract

In the field of tissue engineering, particularly over the last twenty years, biomaterial scaffolds, cells, pharmaceuticals, and biochemical signals are used to produce structures that mimic both the structure and functionality of natural tissue [1]. In this study, reduced human hair keratin (rKRT) based hydrogels were designed for tissue engineering. Moreover, modified gelatin was used to create scaffolds environment for prepared hydrogels. The effects of the presence of keratin on mimicking tissue were evaluated both chemically and biologically for the prepared materials. In the study which was presented here, modified gelatin was used as a support platform for keratin at a lower amout (5% w/v), and the chemical and biological effects of keratin in increasing concentrations were examined. Prepared hydrogels were revealed through chemical characterization, while biological assessment evaluated the effects of keratin presence on cell growth, proliferation, and spreading. The properties of keratin added to structures prepared in different ratios were thoroughly evaluated and discussed in detail.

Abstract

Amphotericin B is a potent antifungal agent; however, its clinical utility is constrained by the severe side effects associated with systemic administration and by its poor skin permeability, which renders topical delivery ineffective. Microneedle patches offer a minimally invasive, painless, and patient-friendly approach that can penetrate the stratum corneum and thereby markedly enhance transdermal drug transport. Moreover, the use of biocompatible and biodegradable polymers in microneedle fabrication provides an optimal platform for safe insertion and efficient transdermal delivery of therapeutic agents. In this study, microneedle patches were fabricated via a casting method using polyvinyl alcohol, gelatin, and hyaluronic acid. Polyvinyl alcohol provides mechanical strength and structural stability, gelatin enhances biocompatibility and contributes to flexibility, and hyaluronic acid provides excellent moisture retention while supporting sustained drug release. Microscopic analysis revealed that the resulting microneedle patches were successfully fabricated as sharp pyramidal structures with an average height of 720 ± 10.9 μm. The chemical composition and thermal stability of the polymeric microneedle patches were characterized by FTIR and TGA, respectively. *In vitro* insertion studies using parafilm confirmed that the microneedle patches penetrated up to the fourth layer, demonstrating sufficient mechanical strength for effective skin insertion. *In vitro* drug-release experiments showed that cumulative AmB release exceeded 50% within the first 2 hours and ultimately reached 93% after 8 hours. Overall, the developed microneedle patches take advantage of both the benefits of microneedle technology and the complementary properties of polyvinyl alcohol, gelatin, and hyaluronic acid, providing a promising strategy for improved transdermal delivery of Amphotericin B in cutaneous antifungal therapy.

Abstract

This study was conducted to determine the biological diversity, spatial distribution, and ecological characteristics of species belonging to the subphylum *Tunicata* in İzmir Bay. Surveys carried out at 45 selected stations revealed a total of 21 species, representing 2 orders, 8 families, and 14 genera. Of these 21 species, five were colonial and seventeen were solitary forms. Among the identified species, *Styela clava*, *Polyclinella azemai*, and *Corella parallelogramma* were recorded for the first time from the Aegean Sea coast of Türkiye. Within the 14 identified genera, *Styela* and *Microcosmus* were the most dominant (three species each), followed by *Botrylloides* and *Ciona* with two species each. The most abundant species was *Microcosmus exasperatus*, exhibiting a dominance value of 44%. Environmental variables measured at the sampling stations ranged between 18.7–28.0°C for temperature, 36.5–39.7‰ for salinity, 6.05–8.51 for pH, and 2.74–8.61 mg/L for dissolved oxygen. Eight of the 21 species (*Ascidiella aspersa*, *Ciona robusta*, *Didemnum maculosum*, *Diplosoma listerianum*, *Microcosmus exasperatus*, *Polyclinum constellatum*, *Styela clava*, *S. plicata*) were classified as alien or invasive. Among these, four species (*P. constellatum*, *M. exasperatus*, and *S. canopus*) were identified as Lessepsian migrants. İzmir Bay is a region rich in tunicate diversity and provides favorable environmental conditions for the establishment of non-native species.

Abstract

Folic acid (vitamin B9) is an essential biomolecule that plays a critical role in DNA synthesis, cellular division, and methylation processes. Abnormal folate levels are directly associated with neural tube defects, anemia, cardiovascular diseases, and various cancers, highlighting the urgent need for rapid and reliable analytical tools for its detection [1]. In this study, we report the fabrication of a novel electrochemical sensing platform based on a pencil graphite electrode (PGE) modified with poly(L-proline) and graphene to achieve enhanced electrocatalytic activity toward folic acid. The Poly(L-proline)/Graphene/PGE electrode was prepared via cyclic voltammetric electropolymerization in the potential range of –0.6 to 2.0 V for 10 cycles in 0.1 M pH 7.4 PBS solution containing 5.0 mM L-proline 1.0 mg/mL graphene and 0.1 M $LiClO_4$. The synergistic combination of graphene with high conductivity and the functional groups of poly(L-proline) provided an improved electron-transfer interface [2]. Comprehensive electrochemical characterization, including cyclic voltammetry (CV), differential pulse voltammetry (DPV), and electrochemical impedance spectroscopy (EIS), will be performed to evaluate the sensor's kinetic behavior, charge-transfer properties, and analytical performance. Optimization studies will systematically investigate the effects of monomer concentration, graphene mass loading, electropolymerization cycle number, and solution pH on the folic acid response. Additionally, morphological and spectroscopic characterizations will be carried out using scanning electron microscopy (SEM) and Fourier-transform infrared spectroscopy (FT-IR), respectively, to confirm the structural features of the modified surface. The sensor will further be validated using real samples to demonstrate its practical applicability. Overall, the proposed Poly(L-proline)/Graphene/PGE platform offers a promising, cost-effective, and efficient sensing strategy for the sensitive determination of folic acid in physiological conditions [3].

Abstract

In recent years, the urea moiety has been regarded as one of the fundamental pharmacophores in drug design. This is largely attributable to the functional properties of the urea group: the amino substituent acts as potent hydrogen-bond donor, while the carbonyl oxygen serves as a hydrogen-bond acceptor. Consequently, the urea functionality has been employed at the rationale design of antiproliferative agents, by enhancing molecular interactions, and receptor affinity. Indeed, several urea-based derivatives (such as sorafenib, regorafenib, and linifanib) have been approved by the FDA as anticancer therapeutics (Farag et al., 2020). In this regard, novel urea compounds were synthesized and characterized by different spectroscopic methods (IR, ^{1}H-NMR, ^{13}C-NMR and MS). And also, their anticancer potential was evaluated against different cell lines, by using MTT method.

Keywords: Urea, synthesis, anticancer activity.

Abstract

This study investigates the molecular, electronic, and spectroscopic properties of 3-ethyl-4-[3-methoxy-2-(4-methoxybenzoyloxy)-benzylideneamino]-4,5-dihydro-1*H*-1,2,4-triazol-5-one using Density Functional Theory (DFT). Geometry optimization was performed at the B3LYP level, and vibrational frequencies were calculated using the 6-311G basis set. Scaled theoretical IR frequencies were compared with experimentally obtained IR data to assess the accuracy of the computational method. Furthermore, ^{1}H and ^{13}C NMR chemical shifts were computed using the GIAO method and compared with experimental NMR spectra. Electronic properties, including E_{HOMO}, E_{LUMO}, dipole moment, polarizability, and hyperpolarizability, were also examined to provide deeper insights into the reactivity and nonlinear optical behavior of the titled compound. The results confirm that the selected theoretical models yield reliable predictions consistent with experimental observations, providing a comprehensive understanding of the physicochemical properties of the studied triazole derivative.

Abstract

Antimicrobial resistance is one of the main problem for the public health. The biofilm structures can lead to less susceptibility to antimicrobials and can cause antimicrobial resistance. *Satureja thymbra* L. is a threatened endemic Mediterranean plant and it has aromatic natural compounds for medicinal purposes. In this study, we aimed to investigate the antimicrobial activities of four types of extracts (Ethanol, hexane, ethyl acetate and methanol) of the plant against 6 bacteria (*Staphylococcus aureus*, *Enterococcus faecalis*, *Bacillus subtilis*, *Escherichia coli*, *Pseudomonas aeruginosa*, *Salmonella enterica*) and 3 fungi (*Candida albicans*, *Candida parapsilosis*, *Candida kruzei*). Inhibition zone diameter and minimum inhibitory concentration (MIC) values were determined by disk diffusion test and microdilution method. Alteration in the biofilm production and mature biofilm levels were determined by spectrophotometric microplate method. Synergistic activities of the extracts/antimicrobials (Gentamicin and fluconazole) were investigated by checkerboard assay. All the experiments were performed in triplicate, and the statistical analyses were performed. According to the results, mean inhibition zone diameters were detected between 7-11 mm with hexane extract against all studied microorganisms. MIC values of extracts were between 64 and 256 µg/mL against studied bacterial and fungal strains. Biofilm production levels of all Gram-negative bacteria and fungi were inhibited in the presence of the four extract at MIC values, as mature biofilm levels were also inhibited in the presence of the extracts at MIC in 5 of 9 strains. Synergistic activities of ethyl acetate extract+gentamicin/fluconazole and methanol extract+gentamicin/fluconazole were detected against 4 of 9 strains. Some of the combinations also demonstrated inhibitory effects against biofilm structures. In conclusion, antimicrobial potential of polar/apolar extracts of *Satureja thymbra* L. investigated and we believe that combating biofilm structures and combined use of compounds of natural origin and synthetic agents may have important role in the control of antimicrobial resistance and infectious diseases.

Keywords: *Satureja thymbra*, Antibacterial activity, Antifungal activity, Antibiofilm activity, Synergistic activity.

Abstract

The aim of this study was to investigate the biocompatibility and anticancer activities of extracts of *Lavandula intermedia* and *Lavandula angustifolia* species grown in Türkiye, collected from two different locations, using hexane and chloroform solutions in a Soxhlet apparatus, on human breast adenocarcinoma cell line (MCF-7) and healthy mouse fibroblast cell line (L929) under in vitro conditions. The cytotoxicity of the extracts at two different concentrations (1mg/mL and 0.5mg/mL) on these two different cell lines was evaluated using MTT (3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide) assay. To determine the activity of these extracts, $5x10^3$ cells were inoculated in 96-well plates and the incubation period was set as 4 hours. The medium containing 1% and 0.5% DMSO in which dry lavender extracts were suspended was used as a negative control. MTT test results were measured at 570 nm wavelength by UV spectrophotometer at the end of 4 hours of incubation to determine the cytotoxicity rates of the extracts. According to the 24-hour MTT data obtained, the cell viability rates were recorded in the hexane extracts of Eskişehir-Belpınar and Bilecik-Bozüyük samples at concentrations of 1 mg/mL and 0.5 mg/mL in the MCF-7 cell line as (39.14% and 37.01%) and (33.70% and 30.21%), respectively. Cell viability rates were recorded in the chloroform extracts of Eskişehir-Belpınar and Bilecik-Bozüyük samples as (47.98% and 38.99%) and (38.76% and 36.49%) respectively. The cell viability rates were determined in the hekzan extracts of Eskişehir-Belpınar and Bilecik-Bozüyük samples at concentrations of 1 mg/mL and 0.5 mg/mL in the L929 cell line as (100.06% and 63.21%) and (96.31% and 66.89%) respectively. Cell viability rates were observed in the chloroform extracts of Eskişehir-Belpınar and Bilecik-Bozüyük samples as (98.25% and 63.09%) and (99.75% and 60.24%) respectively. These findings indicate that lavender extracts produce cytotoxic effects on MCF-7 cancer cells, while exhibiting relatively higher biocompatibility in healthy cells. According to the results, the effects of differences in the biochemical contents of samples collected from different locations and extracts isolated with different solvents on the anticancer activity of the lavender plant were discussed. Lavender is a popular medicinal and aromatic plant whose commercial production has recently increased rapidly in Türkiye and which has a wide range of uses in various sectors. In conclusion, this study highlights the natural effectiveness of medicinal and aromatic plants in cancer treatment and demonstrates that the anticancer effects of lavender species constitute an important preliminary study that can guide future advanced research. Furthermore, by highlighting the potential value of lavender's natural bioactive compounds, it is concluded that it will contribute to the development of new perspectives on cancer treatment.

Abstract

In this study, we aimed to investigate the genetic diversity, genetic differentiation, and population genetic structures of five certified barley (*Hordeum vulgare* L.) varieties (Arcanda, Burak, Emon, Larende, and Tarım 92) using five ISSR primers. According to the molecular analysis results, the five ISSR primers produced 40 loci, 39 of which (97.5%) were polymorphic. The average allele (na), effective allele (ne), genetic diversity (h), Shanon index (I), and polymorphic loci (PL) numbers among the populations were observed as 1.98, 1.63, 0.36, 0.53, and 39 (97.5%), respectively. Among all varieties, the highest values were detected in Arkanda as 1.50, 1.40, 0.22, 0.32, and 20 (50%), respectively. The total genetic diversity (*H*t), genetic diversity within populations (*H*s), genetic differentiation between populations (G_{ST}), and gene flow between populations (*N*m) produced by the primers in five populations were determined as 0.36, 0.13, 0.63, and 0.3, respectively. According to the genetic distance data among barley varieties, the highest genetic distance (D = 0.55) was observed between Emon and Burak varieties, while the lowest genetic distance (D = 0.22) was observed between Burak and Arcanda varieties. Based on the genetic distance data, Emon was grouped as an outgroup compared to other barley varieties in the dendrogram generated by the UPGMA method. Consequently, it was concluded that certified barley varieties have high levels of genetic diversity and genetic differentiation, and that ISSR molecular markers can be used efficiently in barley plants and produce productive results.

Abstract

Plants have been used for many purposes, such as nutrition, fuel, medicine, and ornament, for centuries. The firethorn plant (*Pyracantha coccinea* Roemer var. lalandi) is a plant planted for ornamental purposes. It has small, red, and eye-catching fruits. This study aimed to determine the in vitro biological activity (antioxidant and antidiabetic) of the red fruits of the plant, in addition to its ornamental use. Ethanol and acetone and extracts of the fruits were taken. In antioxidant activity analyses of fruit extracts, $DPPH^{\cdot}$ and $ABTS^{\cdot+}$ radical scavenging powers were determined. Ascorbic acid was used as the standard substance. In the determination of antidiabetic activity; α-amylase enzyme was used. α-amylase enzyme inhibition of the extracts was examined. Again, the drug acarbose was used as the standard substance. The results of the study were calculated as both % inhibition and IC_{50} (inhibitory concentration) values. The $DPPH^{\cdot}$ radical scavenging activity of the extracts was determined as standard ascorbic acid > ethanol extract > acetone extract, respectively. $ABTS^{\cdot+}$ radical scavenging activities were determined as ascorbic acid > acetone extract > ethanol extract. In addition, the α-amylase enzyme inhibition of the extracts was examined, and their antidiabetic activities were determined. Antidiabetic results were determined as standard acarbose > ethanol extract > acetone extract. As a result, it can be said that the fruits of this plant have both antioxidant and antidiabetic activities. In addition, it is thought that this study will contribute to the literature on this plant.

Abstract

Global population growth and the continuing rise in per capita fish consumption are increasing pressure on water resources. Due to the inadequacy of traditional fisheries management tools, a significant portion of global fish stocks are subject to overfishing. This situation highlights the importance of eco-labels, which are market-based tools that promote sustainability. This study examines the function of eco-labels in supporting sustainable fishing practices and their impact on consumer behavior. In this study, the concepts of sustainable fisheries and marketing are first addressed; subsequently, the role of eco-labels as environmental and social product information programs is evaluated within a theoretical framework. International certification programs such as the Marine Stewardship Council (MSC), Friend of the Sea (FOS), Iceland Responsible Fisheries (IRF), and Alaska Responsible Fisheries Management (RFM) were comparatively analyzed. In line with empirical studies in the literature, consumers' awareness levels of eco-labels and their willingness to pay (WTP) a premium for certified products were examined. The findings indicate that eco-labels provide significant benefits in terms of enhancing market access, improving fisheries management, and strengthening consumer trust. However, the findings also indicate that while awareness levels are low among younger consumers, there is a positive correlation between increased awareness and a higher willingness to pay. The study also found that consumers with higher levels of education and spending capacity show a greater willingness to pay a premium for eco-labeled products. In conclusion, eco-labels are an effective tool for enhancing transparency and credibility in sustainable seafood supply chains. To strengthen this impact, it is necessary to develop communication strategies aimed at increasing consumer awareness.

The effect of 1-methylcyclopropane treatments on phenolic compounds in 'Ekmek' quince fruit

Nurdan Tuna Güneş (Orcid: https://orcid.org/0000-0002-8529-2211)

Ankara University, Faculty of Agriculture, Department of Horticulture, Ankara, Türkiye

Corresponding author e-mail: tuna@agri.ankara.edu.tr

Abstract

Türkiye is one of important countries in quince production. Quince is a fruit that contributes to national income in international trade as well as domestic consumption. However, in this fruit species, there is a significant quality loss during long storage period due to late harvest time and inappropriate temperature and relative humidity regimes applied during cold storage period. These losses are mostly due to colour changes caused by oxidation of phenolic compounds, which is called fruit flesh browning. This study was carried out to determine the effect of 1-methylcyclopropene (1-MCP) treatments at two different concentrations of 300 ppb and 1000 ppb after harvest on the change of phenolic compounds in fruit tissue of 'Ekmek' quince cultivar. The study, which was carried out consecutively for 2 years, was carried out with 3 repetitions and using 10 fruits in each replication. In the study, after 1-MCP was applied to the quince fruits harvested at commercial maturity at 300 ppb and 1000 ppb concentrations at 12 °C, they were stored for 6 months in a cold storage with a temperature of 0±1 °C and a relative humidity of 85-90%. Phenolic compounds were determined in fruit tissue samples taken from the cold storage at monthly intervals by using high pressure liquid chromatography (HPLC). At the end of the study, 5-caffeoylquinic acid was determined as the most dominant phenolic compound in 'Ekmek' quince fruits. It was observed that 1000 ppb of 1-MCP treatment during the storage period f six months slowed down the change in phenolic compounds in fruit. For this reason, it seems that 1000 ppb 1-MCP treatments can be taken into consideration as a promising postharvest technology for 'Ekmek' quince fruit.

Keywords: 5–caffeoylquinic acid, storage, quality, postharvest.

Abstract

The study was carried out with the aim of improving the fruit quality of the '0900 Ziraat' cherry cultivar, which is an important cherry cultivar for Türkiye and has an important place in our cherry export income. For this purpose, the effect of different concentrations of salicylic acid treatments was examined. In the study, salicylic acid treatments were performed by adding 0.2% Tween 20 and three different concentrations such as 100 ppm, 150 ppm and 200 ppm salicylic acid were applied when the fruit was at transition stage from yellow skin colour to pink skin colour stage. To determine the effect of salicylic acid treatments on some physical properties of fruits, fruit weight, fruit age and length, fruit surface area and fruit volume were determined in the samples taken at commercial harvest time. The study was carried out in 3 replications and each replications included 25 fruits. Overall, it was determined that 150 and 200 ppm salicylic acid treatments led to an increase in fruit size compared to the control groups and these treatments did not cause cracking in the fruits.

Keywords: fruit weight, fruit width, size, quality, postharvest.

Abstract

In this study, the corrosion inhibitor effect of hazelnut shell ash (HSA) at different concentrations (10 mL, 25 mL, 75 mL) in 1% NaCl solution on iron (Fe) was investigated using electrochemical methods. The methods with open circuit potential (E_{OCP}), electrochemical impedance spectroscopy (EIS), and current-potential (Tafel) curves showed that the addition of HSA significantly shifted the potential in the cathodic direction and that the solution became basic (pH 5.8 to ~10) at all concentrations. Furthermore, corrosion resistance increased from 866 Ω·cm² to 2450 Ω·cm², providing an improvement of ~65%. Inductively Coupled Plasma - Mass Spectrometer (ICP-MS) analyses revealed a significant decrease in Fe ions passing into the solution, consistent with the electrochemical results. The HSA has been shown to have the potential to be an effective, environmentally friendly corrosion inhibitor in study solutions for Fe at 25ºC. It was determined that HSA adsorbed more effectively onto the metal surface at low concentrations (10 mL), reaching an adsorption efficiency of 70% under these conditions.

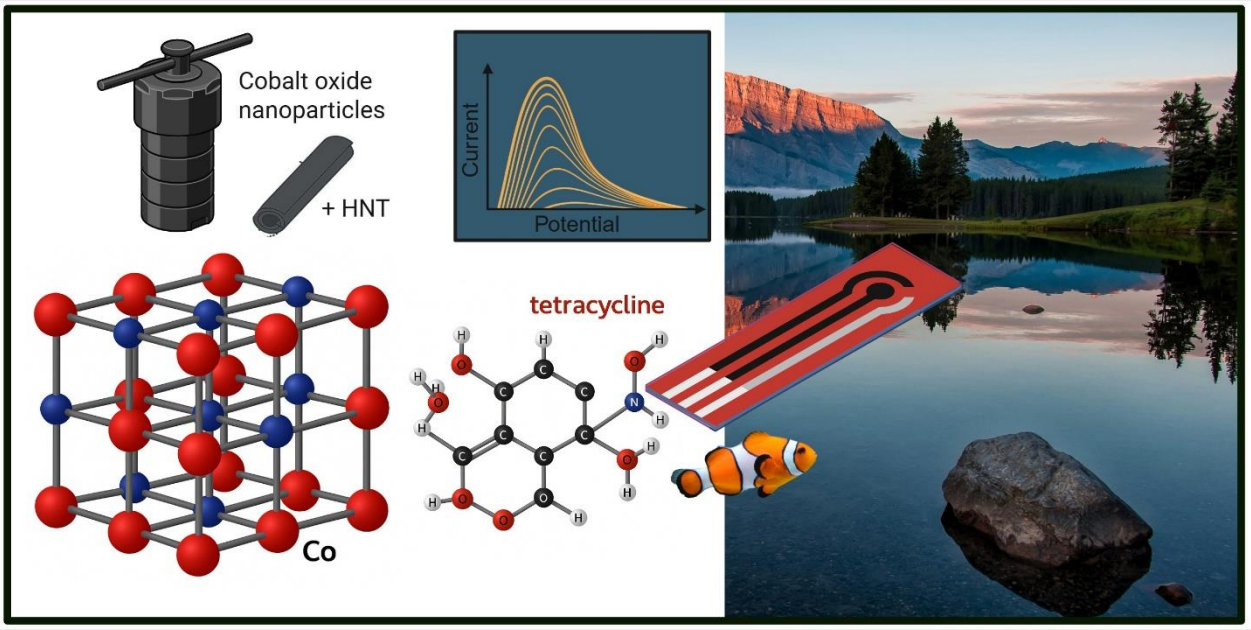
Cobalt oxide/halloysite nanotubes for enhanced electrochemical sensing of tetracycline



Meltem Okan (Orcid: https://orcid.org/0000-0002-7253-9801)

METU MEMS Center, Ankara, Türkiye

Corresponding author e-mail: okanmelt@gmail.com

Abstract

Antibiotic contamination in aquatic environments poses a major threat to ecological and human health, underscoring the need for rapid and sensitive detection platforms. In this study, the development of a cobalt oxide nanoparticles-halloysite nanotube (CoO/HNT) nanohybrid-based electrochemical sensor for the quantitative detection of tetracycline residues in environmental water samples is reported. CoO nanoparticles were synthesized via a hydrothermal route and immobilized onto the surfaces of halloysite nanotubes to achieve a high-surface-area hybrid with enhanced electroactive sites, improved electron mobility, and strong adsorption affinity for tetracycline molecules. The structural and morphological characteristics of the nanohybrid were confirmed by SEM, TEM, XRD, and FTIR analyses, revealing uniform CoO nanoparticle decoration and the preservation of the tubular HNT architecture. Screen printed carbon electrodes modified with the CoO/HNT composite exhibited a substantially increased redox response toward tetracycline compared to pristine HNT and CoO-only controls, demonstrating the synergistic catalytic activity of the hybrid. Cyclic voltammetry (CV) and differential pulse voltammetry (DPV) studies indicated fast charge-transfer kinetics and a well-defined oxidation peak associated with tetracycline. Under optimized conditions, the sensor delivered a wide linear range, low detection limit, and excellent sensitivity suitable for trace-level environmental monitoring. Repeatability, inter-electrode reproducibility, and long-term stability tests confirmed the robustness of the sensing platform. The CoO/HNT-modified electrode was successfully applied to spiked wastewater samples, achieving high recovery rates and minimal matrix interference, confirming its practical applicability for real-world analysis. Overall, this work introduces a cost-effective, stable, and highly responsive CoO/HNT nanohybrid material for the electrochemical detection of tetracycline, offering a promising approach for routine environmental surveillance of antibiotic pollutants.

Abstract

Lead (Pb) is a highly toxic heavy metal that poses significant threats to all organisms due to its bioaccumulation and biomagnification along the food chain. This study evaluated the effectiveness of *Hygrophila corymbosa* (Blume) Lindau in removing Pb from contaminated freshwater environments and assessed its overall suitability as a phytoremediation species. To achieve this, plants were exposed to different concentrations of $Pb(NO_3)_2$ (0, 10, 25, 50, and 100 µM) for 10 days. Washed and unwashed roots, stems, and leaves were analyzed for Pb accumulation and changes in mineral nutrient content (B, Ca, Cu, Fe, K, Mg, Mn, Na, and Zn) using ICP-OES. Additionally, total chlorophyll content was measured to assess physiological responses to Pb stress. The results showed a significant decrease in mineral nutrient concentrations and a moderate decline in total chlorophyll contents with increasing Pb exposure compared to the control group. Total chlorophyll contents were recorded as 10.51, 9.33, 6.33, 8.5, and 10.45 mg m^{-2} at 0, 10, 25, 50, and 100 µM Pb concentrations, respectively. Pb accumulation in roots, stems, and leaves increased proportionally with the applied Pb concentrations. *H. corymbosa* exhibited a strong Pb accumulation capacity, with overall bioconcentration factors (BCF) of 27, 20, 15, and 14; translocation factors (TF) from stem to leaf of 1.8, 1.2, 1.2, and 1.1; TF from root to stem of 0.6, 1.02, 0.96, and 0.90, and from root to leaf of 2.43, 2.18, 2.16, 2.04 at 10, 25, 50, and 100 µM Pb, respectively. In conclusion, Pb-induced imbalances in mineral nutrients and total chlorophyll concentrations resulted in physiological stress in *H. corymbosa*. However, the plant's high Pb accumulation, high BCF, low TF values suggest tolerance to Pb toxicity and underscore its potential for phytoremediation of Pb-contaminated freshwater ecosystems.

Abstract

Despite numerous studies, cancer remains a serious health problem worldwide. Current chemotherapeutic agents are inadequate due to the accumulation of mutations and the development of multidrug resistance, leading to a high risk of side effects. This has increased the need for new agents that can exhibit selective cytotoxic and antiproliferative effects in cancer cells. Apigenin, a phytochemical flavonoid, is distinguished by its antioxidant and anti-inflammatory properties and may exhibit potential therapeutic effects in cancer cells. One of the processes that plays a critical role in cancer progression is angiogenesis, and the literature reports that VEGF is the primary factor promoting new vessel formation in tumors, playing a key role in tumor growth and metastasis. Similarly, the COX-2 enzyme has been shown to contribute to tumor cell proliferation and angiogenesis by increasing prostaglandin production, thus promoting cancer progression. This study aims to investigate the cytotoxic and potential anti-angiogenic effects of Apigenin on the human breast cancer cell line MDA-MB-231 in vitro.
Cell viability was assessed by MTT analysis after application of different doses of apigenin and cisplatin to the cells for 24, 48, and 72 hours. According to the results, the IC_{50} value of apigenin at 48 hours was determined to be 12.89 µM, and the IC_{50} value of cisplatin was determined to be 5.84 µM. Immunocytochemical analyses at IC_{50} concentrations examined changes in VEGF and COX-2 expression levels, and the antiproliferative and potential anti-angiogenic effects of apigenin in MDA-MB-231 cells were evaluated.
The findings suggest that Apigenin may exhibit antiproliferative effects in breast cancer cells, and these effects warrant further evaluation in detail through additional studies.

Abstract

Breast cancer is the most common malignancy among women and represents a significant global health issue due to its increasing incidence and mortality rates. Current statistics indicate a marked rise in new cases and deaths in the coming years. Despite advances in surgery, radiotherapy, chemotherapy, and targeted therapies, challenges such as multidrug resistance, systemic toxicity, metastasis, and recurrence limit effective clinical management. Aggressive triple-negative breast cancer (TNBC), which lacks hormone receptors and HER2 expression, particularly highlights the need for new, selective, and less toxic therapeutic agents due to its limited treatment options and poor prognosis. Diarylurea scaffolds play an important role in the development of new and effective agents against breast cancer. The preference for the diarylurea skeleton in anticancer drugs arises from the ureido group's ability to form strong and selective interactions with binding sites of target proteins. The oxygen atom in the ureido functional group can act as a hydrogen bond acceptor, while the NH group can serve as a hydrogen bond donor, facilitating high-affinity binding of these compounds to biological targets. Therefore, diarylurea derivatives are considered promising candidates in anticancer drug development studies, particularly for inhibiting pathways that play critical roles in proliferation and survival signaling. In this context and as a continuation of our efforts to develop novel anticancer agents, the present study focused on the design of new ureido derivatives based on N-Phenyl-N′-(4-pyridylmethyl)urea. The target molecules were synthesized by reacting 4-picolylamine with different phenyl isocyanate derivatives, resulting in the formation of 11 distinct N-Phenyl-N′-(4-pyridinylmethyl)urea (PPU) derivatives. The structures of the synthesized compounds were confirmed by ^{1}H NMR, ^{13}C NMR, and HRMS analyses, and their biological activities were investigated in MCF-7 and MDA-MB-231 breast cancer cell lines in comparison with cisplatin. (This study was derived from the master's thesis entitled “Synthesis and Investigation of Biological Activities of Hybrid Compounds Containing 2,4-Disubstituted-1,3-Thiazole and Different Azole Groups” conducted at the Department of Pharmaceutical Biochemistry, Institute of Health Sciences, Erciyes University.)

Abstract

Growth and reproductive traits, among the most economically critical functional characteristics in animal production, emerge as a result of the interaction between genetic and environmental factors. Understanding the genetic basis of these traits is crucial for developing sustainable selection programs that aim to increase productivity, particularly in goat breeding. However, the fact that multiple genes control these characteristics makes it difficult to explain the effects of genetic variations. The *POU1F1* pathway is a crucial pathway that plays a vital role in pituitary development and the regulation of growth and reproductive hormones. Determining the hormones affected by the genes in this pathway and the traits influenced by the pleiotropic genes involved is highly important for both animal health and breeding goals. However, there is insufficient information on this subject in goats. In this context, the aim was to determine the frequencies of the *PITX1* (c.490G>A), *PITX2* (g.18353T>C), *LHX3* (g.8035T>C), *PROP1* (c.236C>T), and *POU1F1* (c.837T>C and c.771+215C>T) polymorphisms located in the *POU1F1* pathway and to demonstrate the relationship of these polymorphisms with growth and reproductive traits in Saanen goats. In the study, a total of 150 Saanen goats were genotyped. The relationship with growth and reproductive traits, including birth weight, litter size, daily weight gain, total weight gain, first breeding weight, body length, heart girth, rump width, rump height, and wither height, was examined. Within this scope, it was determined for the first time in this study that the *LHX3* (g.8035T>C) polymorphism was significantly associated with the number of litter size ($P<0.05$), and the *PITX1* (c.490G>A) polymorphism had a tendency to affect birth weight ($P<0.1$). The findings, presented for the first time in the literature by this study, make significant contributions to elucidating the genetic basis of growth and reproductive traits in goat breeding. The obtained results indicate that the *POU1F1* gene pathway and the polymorphisms in related genes can be evaluated as potential molecular markers in future breeding programs.

Abstract

Multi-walled carbon nanotubes (MWCNTs) possess exceptional electrical conductivity, high surface area, and unique pore characteristics, making them highly promising materials for advanced electrochemical energy-storage applications. In this study, the capacitive behavior of MWCNTs was systematically investigated using electrochemical techniques to evaluate their suitability for supercapacitor electrode design. For this purpose, after commercial multi-walled carbon nanotubes (MWCNTs) were structurally characterized using scanning electron microscopy (SEM), energy-dispersive X-ray spectroscopy (EDS), Fourier transform infrared spectroscopy (FTIR), and X-ray diffraction (XRD), carbon felt electrode (CFE) was modified with MWCNT via drop casting technique. The capacitive properties and energy storage mechanism of MWCNT modified CFE were elucidated using electrochemical techniques, including cyclic voltammetry (CV), electrochemical impedance spectroscopy (EIS), and galvanostatic charge–discharge (GCD). The energy density, power density, and coulombic efficiency of the MWCNT–CFE system were calculated using GCD measurements. Future studies are expected to explore MWCNTs combined with metal–organic frameworks (MOFs) and other nanomaterials to enhance supercapacitor electrode performance. Such composites can improve specific capacitance, energy density, and cycling stability through synergistic effects of high surface area, hierarchical porosity, and efficient electron/ion transport, paving the way for next-generation energy storage devices.

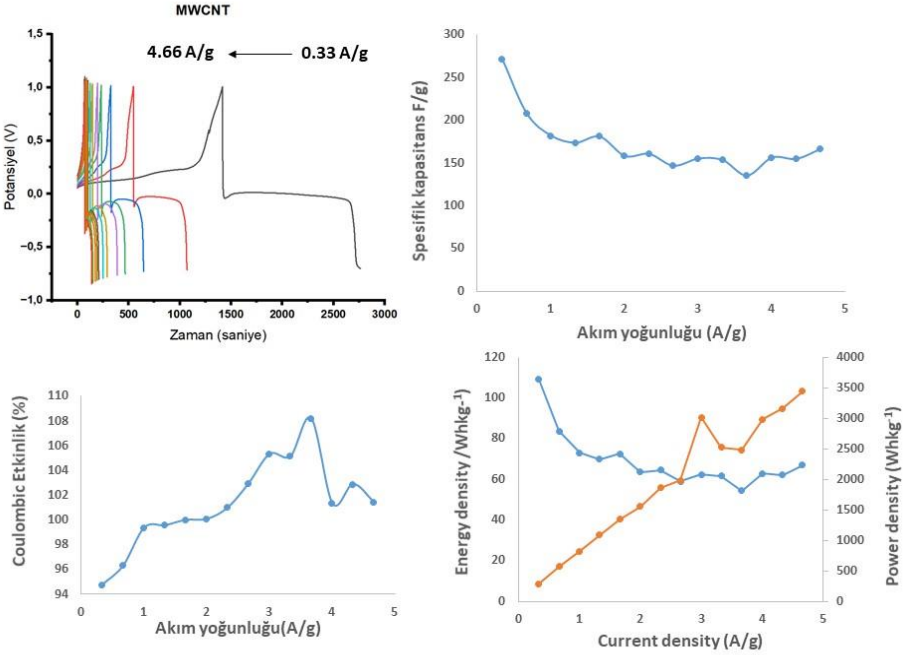

Figure 1. Figures showing the GCD results of the MWCNT/CFE system, as well as the specific capacitance, coulombic efficiency (%), power density, and current density values.

Keywords: MWCNT, Supercapacitor electrodes, carbon felt electrode, composite electrode.

Abstract

The rapid increase in global energy demand and the depletion of fossil fuel reserves have significantly heightened interest in sustainable and eco-friendly resources, such as hydrogen (H_2) energy. However, challenges regarding the safe and efficient storage of H_2 remain one of the major obstacles hindering the development of the H_2 economy. Therefore, technological challenges related to storage and utilization must be addressed. In this study, carbons possessing high surface area and pore volume were produced from Zonguldak coal via molten salt activation followed by acid treatment. During the experimental phase, the activation process was conducted at 800°C using a coal mixture with KOH and K_2CO_3 salts. Post-activation, the resulting carbon structures were treated with HCl and HF acid to yield comparative porous carbon samples. The characterization of the porous carbon materials was performed using SEM-EDS, BET surface area analysis, and measurements of pore volume and distribution. The results demonstrated that HF treatment significantly enhanced the material's textural properties. Specifically, the BET surface area increased from 541 m^2/g to 1249 m^2/g following HF treatment. Correspondingly, the H_2 adsorption capacity rose from 88 cm^3/g to 195 cm^3/g. These experimental findings suggest that molten salt activation with KOH and K_2CO_3, combined with HF acid treatment, is a highly effective method for enhancing the pore characteristics of coal-based materials and improving their H2 storage performance.

Abstract

Meat consumption plays a crucial role in meeting individuals' essential nutritional needs. Animal products such as red meat, white meat, and fish play a crucial role in human nutrition because they contain high-biological-value protein and provide essential micronutrients such as iron, zinc, phosphorus, and vitamin B12. Therefore, adequate and balanced consumption of meat products is considered a key indicator of a healthy lifestyle. Meat consumption levels are influenced by multiple factors, including an individual's nutritional knowledge, lifestyle, cultural values, religious preferences, and socioeconomic circumstances. Various studies have shown that individuals with a high level of health knowledge are better able to assess the nutritional differences between meat types and are more aware of saturated and unsaturated fat content and the health effects of processed meat consumption. It is well established that the knowledge and attitudes acquired during professional training have a significant impact on the nutritional behaviors of healthcare professionals. Generally speaking, the meat consumption habits of healthcare workers are influenced by multifaceted factors such as their knowledge level, professional awareness, economic conditions, and work schedules. Therefore, studies on meat consumption among healthcare workers provide important data for understanding healthy eating behaviors, promoting nutritional awareness in society, and informing policy development processes. This study aims to determine the meat consumption habits of Erciyes University healthcare workers, the factors influencing these preferences, and the importance of these factors using the Analytical Hierarchy Process (AHP) method. In the AHP form, participants were asked to evaluate meat types (beef, lamb, chicken, turkey, and fish) on the criteria of Health, Price, Taste, Hygiene and Reliability, Halal, Habit/Cultural Preference, and Accessibility using a pairwise comparison scale (1–9). At the end of the study, the meat consumption preferences of healthcare workers were determined using an analytical hierarchy process, and it was revealed that health was the most important criterion and that fish meat was preferred more. Chicken meat was also preferred due to its low price.

Abstract

DIACEST agents represent a promising metal-free alternative for MRI contrast via exchangeable proton groups (hydroxyl, amine, amide, carboxyl) (1-5). A computational platform was needed for predicting relaxation properties under various physiological and technical parameters, and enabling rapid screening and optimization prior to synthesis and experimental validation (6-10). Thus, this work developed an in silico platform to estimate longitudinal and transverse relaxation rate changes (11-14). The software offers a comprehensive interface with functional modules to streamline the simulation process. The setup allows users to upload molecular structures and define physiological conditions alongside scanner parameters. Signals were estimated from standard spin-echo formulation. Additionally, the software simulates phantoms at various dilution series to visualize contrast enhancement effects. Validation was performed using betanin, and predictions were compared against benchmark real measurements. This platform represents a novel, systematic tool for predicting DIACEST agent behavior, bridging the gap between molecular design and MRI contrast enhancement. The successful validation with betanin demonstrates its utility for virtual screening of theoretical candidates prior to synthesis, as well as the evaluation of already synthesized potential DIACEST compounds.

Abstract

S-metolachlor, a chloroacetanilide herbicide frequently detected in agricultural watersheds, poses potential risks to aquatic organisms through sub-chronic exposure. In this study, rainbow trout (*Oncorhynchus mykiss*) were exposed for 7, 14, and 21 days to three environmentally relevant concentrations of S-metolachlor (0.0123, 0.0615, and 0.123 mg/L). Oxidative stress biomarkers were quantified in spleen and heart tissues to evaluate tissue-specific responses. Antioxidant enzyme activities were significantly elevated, accompanied by increased levels of oxidative damage markers, indicating that compensatory mechanisms were insufficient to prevent cellular injury. Distinct organ-level differences were observed. The spleen maintained protein stability under exposure, whereas the heart exhibited protein depletion and transient antioxidant responses, suggesting greater susceptibility of cardiac tissue. These results demonstrate that even field-comparable concentrations of S-metolachlor can disrupt oxidative homeostasis and tissue metabolism in fish, emphasizing the relevance of organ-specific biomarker assessment and the necessity for more rigorous monitoring of herbicide residues in freshwater ecosystems.

Co-toxicity of pesticides and nano/microplastics in aquatic systems: Implications for fish models

Demet Doğan (Orcid: 0000-0001-6356-0679)

Gaziantep University, Faculty of Arts&Sciences, Department of Biology, Gaziantep, Türkiye

Corresponding author e-mail: demetdogan@gantep.edu.tr

Abstract

Aquatic ecosystems are increasingly challenged by the simultaneous presence of pesticides and plastic-derived particulates, producing complex exposure scenarios that strain conventional toxicological frameworks. Nano- and microplastics, with their pronounced surface reactivity and physicochemical heterogeneity, function as vectors that adsorb and redistribute pesticide residues, thereby reshaping contaminant behavior in aquatic environments. The convergence of these pollutants has been reported to exacerbate toxicological outcomes in fish models, including oxidative imbalance, apoptotic pathways, neurophysiological disturbances, and endocrine disruption. This review synthesizes and critically evaluates current literature on pesticide–plastic interactions, emphasizing mechanistic processes such as adsorption, desorption, and altered bioaccumulation. By collating evidence across molecular, cellular, and organismal levels, the analysis highlights the ecological relevance of multiple stressors and exposes the shortcomings of single-contaminant assessments. The discussion ultimately calls for integrative toxicological perspectives that incorporate co-exposure scenarios to more accurately assess risks to aquatic organisms and ecosystem health.

Impact of agricultural herbicides on aquatic ecosystems: Case of aclonifen

Şeyma Özdemir*, Muhittin Doğan

Gaziantep University, Faculty of Arts and Sciences, Department of Biology, Şehitkamil-Gaziantep, Türkiye

*Corresponding author e-mail: so7392163@gmail.com

Abstract

Herbicides are widely applied in agriculture to enhance crop yield and control weeds; however, their extensive use poses significant environmental risks to aquatic ecosystems. Following application, a considerable proportion of pesticides are transported to non-target environments through surface runoff, rainfall-induced erosion, leaching into groundwater, and atmospheric deposition, ultimately contaminating water resources. These processes contribute to water quality deterioration, chemical accumulation in sediments, and potential biomagnification within food webs. Aclonifen, a diphenyl ether herbicide commonly used in crops such as sunflower, chickpea, and lentil, exerts its phytotoxic effects by inhibiting phytoene desaturase and protoporphyrin oxidase enzymes, leading to bleaching and necrosis in plants. Although strongly adsorbed by soil organic matter and clay, its leaching potential increases under high moisture conditions. Both Aclonifen and its metabolites exhibit moderate acute aquatic toxicity, negatively affecting aquatic plants and invertebrates. The findings highlight that herbicides used in agricultural practices pose considerable ecological and toxicological risks to aquatic systems. Sustainable agriculture therefore requires limiting pesticide use, promoting natural alternatives, implementing precision techniques, and developing appropriate timing strategies.

The importance of vineyard houses in Gaziantep in terms of culture and urban ecology

Mustafa Pehlivan

Gaziantep University, Faculty of Arts&Sciences, Department of Biology, Gaziantep, Türkiye

Corresponding author e-mail: mpehlivan@gantep.edu.tr

Abstract

In our country, vineyard houses, which were built by agricultural producers, especially those with large-scale plots, for the purpose of evaluation during production, have gained much more functional characteristics today. The rapid spatial expansion of cities, transportation opportunities, and the country's seismicity are among the important reasons for this functionalization. Although the vineyard cottage culture in Gaziantep province dates back much further, it has also been affected by this change. Furthermore, the earthquakes that occurred in February 2023, centered in Kahramanmaraş, have contributed to these vineyard cottages becoming increasingly comprehensive structures and transforming into planned “residences.” Furthermore, the fact that these structures served as “shelters” for people during and after the Covid-19 pandemic and subsequently during the earthquake period has increased the demand for them. On the other hand, the fact that water wells have been dug for each vineyard house, along with these structures, can be said to have had a negative impact <on the natural flora and the agricultural sector in recent years of drought. Although well permit applications for areas smaller than a certain size will be evaluated negatively as of 2025, even the existing wells cause significant water losses. The loss is significantly higher when vineyard owners construct pools or allocate lawn areas on their land. While the public's high demand for vineyards and desire for agricultural production could yield positive economic and ecological contributions if properly directed, lack of planning and oversight could worsen the current situation.

Keywords: Vineyard house, culture, urban ecology, economy, Gaziantep

Abstract

This study aimed to comparatively evaluate the antioxidant properties of the acetone (AE), methanol (ME), and water (WE) extracts of *Pyracantha coccinea* M. Roem., a plant known for its rich phytochemical content. Antioxidant capacity was assessed using DPPH radical scavenging and metal chelating assays, while total phenolic, flavonoid, and anthocyanin contents were determined spectrophotometrically. IC_{50} values and slope coefficients were calculated using probit analysis. The AE extract exhibited the strongest DPPH radical scavenging activity, with an IC_{50} value of 56.73 µg/mL (50.98–62.94), followed by the ME extract (69.50 µg/mL) and the WE extract (115.27 µg/mL). Similar trends were observed in metal chelating activity, where AE again showed the highest potency with an IC_{50} of 83.66 µg/mL, compared to 101.77 µg/mL for ME and 173.09 µg/mL for WE. Analysis of antioxidant compounds revealed that AE contained the highest total phenolic content (254.87 µg GAE/mg), total flavonoid content (125.22 µg QE/mg), and total anthocyanin content (2.33 µg C3G/mg). ME and WE extracts displayed lower concentrations of all measured antioxidant components. Overall, the results indicate that the acetone extract of *P. coccinea* demonstrates the strongest antioxidant potential among the evaluated extracts. This enhanced activity is likely linked to its higher phenolic and flavonoid content. The findings suggest that *P. coccinea* may serve as a promising natural source of antioxidant compounds and provide a valuable foundation for further pharmacological and phytochemical studies.

Abstract

Microgreens represent an early developmental stage of edible plants, characterized by their high phytonutrient content and rapid harvestability. Their growing popularity stems from their potential to serve as sustainable, functional food ingredients with enhanced health-promoting properties. In this study, the growth responses of *Eruca sativa* Mill. microgreens to two lichen-derived secondary metabolites—atranorin and usnic acid—were evaluated across five application levels (2, 4, 6, 8, and 10 mg/L). Germination initiated on day three, and plants exhibited typical microgreen morphology, including fully expanded cotyledons and dark green emerging true leaves, by day eight. Both metabolites produced a clear dose-dependent, hormetic pattern of response. Atranorin promoted shoot and root development most effectively at moderate concentrations (4–6 mg/L), whereas usnic acid induced maximal stimulation at comparatively higher doses (8–10 mg/L). The findings indicate that atranorin and usnic acid possess measurable biostimulant potential when applied within optimal concentration ranges, suggesting their applicability in sustainable microgreen production systems as natural growth-enhancing agents.

Abstract

This study investigated the antioxidant capacities and bioactive compound profiles of acetone (AS), ethyl acetate (ETAS), and water (WA) extracts obtained from both microgreen (M-) and mature (O-) stages of *Spinacia oleracea* L. Antioxidant activity was assessed using DPPH radical scavenging and metal chelating assays, while total phenolic and flavonoid contents were quantified spectrophotometrically. In the DPPH assay, mature plant extracts demonstrated higher antioxidant activity than microgreen extracts. The O-AS extract showed the strongest radical scavenging effect with an IC_{50} of 90.13 µg/mL (81.21–100.30), followed by O-ETAS (111.78 µg/mL) and O- WA (147.97 µg/mL). Among microgreen extracts, M-AS exhibited the lowest IC_{50} (148.41 µg/mL), whereas M-ETAS (238.13 µg/mL) and M-WA (248.16 µg/mL) had considerably weaker activity. A similar pattern was observed in metal chelation capacity. The O-AS extract again displayed the highest activity with an IC_{50} of 84.23 µg/mL (75.83–93.75), followed by O-ETAS (105.84 µg/mL) and O-WA (216.00 µg/mL). Microgreen extracts showed higher IC_{50} values, with M-AS at 129.05 µg/mL, M-ETAS at 244.06 µg/mL, and M-WA at 266.77 µg/mL. Total phenolic and flavonoid analyses supported the antioxidant results. Mature extracts contained higher levels of bioactive compounds, with O-AS showing the highest phenolic (523.99 µg GAE/mg) and flavonoid (861.91 µg QE/mg) concentrations. Microgreen extracts displayed lower amounts, particularly in water extracts, where phenolic and flavonoid contents were minimal. Overall, mature *S. oleracea* extracts exhibited significantly stronger antioxidant properties and higher phytochemical content compared to microgreen extracts. The acetone extract of mature plants demonstrated the most potent activity, highlighting its potential as a valuable natural antioxidant source. These findings contribute to the understanding of developmental stage differences in the bioactive composition of *S. oleracea*.

Abstract

This study evaluated the effects of different LED light exposures (white (W), red (R), and blue (B)) on the antioxidant properties and phenolic composition of acetone and water extracts of *Lens culinaris* L. The DPPH radical scavenging results showed that acetone extracts exhibited lower IC_{50} values compared to water extracts. Among all extracts, the blue LED acetone extract (BAS) demonstrated the strongest DPPH scavenging activity with an IC_{50} of 187.59 µg/mL, while the red LED water extract (RWE) showed the weakest activity (586.41 µg/mL). Metal chelation assays revealed that acetone extracts again had higher activity, with the white LED acetone extract (BAS) showing the lowest IC50 value of 36.38 µg/mL, followed by red LED acetone (RAS, 57.10 µg/mL) and blue LED acetone (BAS, 67.92 µg/mL). Water extracts exhibited considerably weaker chelating capacity, with IC50 values ranging between 159.44 and 296.17 µg/mL. Analysis of total phenolic content indicated that BAS had the highest concentration (258.26 µg GAE/mg), whereas WWE had the lowest (164.55 µg GAE/mg). Total flavonoid results demonstrated a strong enhancement under white and blue LED acetone conditions, with BAS (580.06 µg QE/mg) and BAS (585.03 µg QE/mg) showing substantial increases, while water extracts displayed lower flavonoid accumulation except for RWE (513.40 µg QE/mg). Blue LED exposure significantly improved both phenolic composition and antioxidant performance, particularly in acetone extracts. These findings suggest that LED light quality plays a critical role in modulating the bioactive compound profile of *L. culinaris*, with blue LED treatment emerging as the most effective condition for enhancing antioxidant and metal-chelating activities.

Abstract

This study evaluated the phenolic–flavonoid composition and antioxidant potential of microgreen and mature *Eruca sativa* extracts obtained using acetone, ethyl acetate, and water. Total phenolic content ranged from 156.51 to 304.93 µg GAE/mg, with the highest value detected in the microgreen water extract (MWE, 304.93 ± 5.47 µg/mg). Total flavonoid levels varied between 306.33 and 396.04 µg QE/mg, where again the microgreen water extract exhibited the strongest flavonoid content (396.04 ± 1.04 µg/mg). DPPH scavenging analysis revealed IC_{50} values between 100.98 and 153.41 µg/mL for microgreen extracts, and between 119.99 and 152.42 µg/mL for mature plant extracts. The strongest radical scavenging activity was observed in the microgreen water extract (MWE, IC_{50} = 100.98 µg/mL), followed by the mature acetone (OAS, 119.99 µg/mL) and mature ethyl acetate (OEA, 122.67 µg/mL) extracts. Metal chelation capacity showed remarkable differences between microgreen and mature stages. IC_{50} values ranged from 62.27 to 158.41 µg/mL for microgreens, while mature plant extracts exhibited IC_{50} values between 72.56 and 120.31 µg/mL. The most potent chelating activity was recorded in the microgreen water extract (MWE, 62.27 µg/mL) and mature acetone extract (OAS, 72.56 µg/mL). Microgreen extracts, particularly MWE, demonstrated superior antioxidant capacity in both radical scavenging and metal chelation assays, supported by their high phenolic and flavonoid levels. Mature plant extracts also showed significant activity, indicating that both growth stages of *E. sativa* represent valuable sources of natural antioxidants. These findings highlight the potential applicability of *E. sativa*, especially its microgreen forms, in functional food formulations and natural antioxidant development.

Keywords: Antioxidant activity, DPPH radical scavenging, *E. sativa*, Microgreens

Abstract

Artificial intelligence–based diagnostic tools have recently gained increasing attention as complementary technologies for dermatological imaging. Dermatophyte infections, which represent one of the most common groups of superficial fungal diseases, are often difficult to diagnose accurately using traditional visual inspection or microscopy alone. Deep learning models, particularly convolutional neural networks (CNNs), can automatically extract morphological features associated with dermatophytic lesions from dermoscopic and clinical skin images. These models enhance diagnostic precision by learning fine-scale texture differences, erythema patterns, edge characteristics and scaling intensity that may not be easily distinguished by clinicians. Recent studies demonstrate that AI-supported systems can reach accuracy levels comparable to experienced dermatologists, especially in differentiating dermatophyte infections from eczema, psoriasis and bacterial dermatoses. This study provides an overview of state-of-the-art image-based AI applications developed for dermatophyte detection, discussing training dataset requirements, preprocessing workflows, model performance metrics and common challenges related to class imbalance, image noise and variability in illumination. Furthermore, the integration of AI tools with tele-dermatology platforms is evaluated, highlighting their potential use in remote triage, early detection and decision support. Limitations such as the need for standardized image acquisition protocols, dataset diversity and clinical validation processes are also addressed. Overall, AI-driven image analysis offers a promising, fast and reproducible approach to dermatophyte diagnosis. When supported by high-quality datasets and rigorous clinical evaluation, these systems may enhance routine dermatological practice and contribute to more accurate management strategies for superficial mycoses.

Abstract

Cytokines are small protein molecules that facilitate intercellular communication in the immune system and direct immune responses. They are known to play important roles in the mammalian immune system. In mammals, they are produced by macrophages, lymphocytes, mast cells, granulocytes, fibroblasts, epithelial cells, endothelial cells, natural killer cells (NK cells), and T and B lymphocytes. Their key functions include initiating inflammation, promoting cell migration, supporting tissue repair, controlling immune responses, and providing defense against cancer cells. In recent years, in addition to their functions in mammals, cytokines have also been investigated in insects. However, while studies on the fruit fly *Drosophila melanogaster* Meigen (Diptera: Drosophilidae) have identified different cytokines, research on this topic is still limited. *D. melanogaster* cytokines play critical roles in various biological processes, including the insect immune system, development, cell growth, and stress response. Furthermore, specific cytokine groups have the potential to control pest populations by targeting the growth and immune mechanisms of pests. Therefore, cytokines are potential molecules that can be used as biological pesticides in agriculture. In this context, our laboratory is conducting research in this area using model insects such as *D. melanogaster* and the greater wax moth, *Galleria mellonella* L. (Lepidoptera: Pyralidae), to develop environmentally friendly alternatives to insecticides used in agriculture and to minimize their harmful effects on non-target organisms. Our laboratory will also focus on studies examining the effects of these groups of molecules on the survival and development of model insects to uncover the potential effects of cytokines on agricultural pest insects.

*Sorumlu yazar e-mail: buymaz@comu.edu.tr

Özet

Biyojen aminler; hayvan, bitki ve mikroorganizmaların normal metabolik aktiviteleri sonucunda, aminoasitlerin dekarboksilasyonu ile oluşan düşük molekül ağırlıklı azotlu bileşikler olup; biyojen amin içeriği yüksek gıda tüketimi toksik etkilere neden olabilmektedir. Biyojen aminler; hammadde mikroflorasındaki çeşitlilik, kontrolsüz koşullarda gerçekleşen fermantasyon ve çevresel kontaminantlar gibi etkenlerle fermente gıdalarda yüksek derişimlerde bulunabilmektedir. Ev yapımı peynirler, kontrolsüz mikrobiyel yükü ve olgunlaşma sıcaklıkları nedeniyle biyojen amin bakımından en riskli fermente gıda grubu olarak değerlendirilmektedir. Çalışmada Çanakkale'nin Bayramiç ilçesinde starter kültür kullanılmadan, evlerde geleneksel yöntemlerle işlenerek olgunlaştırılan; tüketilen ve/veya ilçe pazarında satışa sunulan peynir örneklerinden *(i)* Enterokok cinsi türlerin izolasyonu *(ii)* izolatların kısmi karakterizasyonu (Eskulin hidrolizi, pH 9,6'da gelişim, tuz (%6,5 NaCl) ve sıcaklık (10°C ve 45°C) tolerans düzeyleri) yapılmış olup ayrıca *(iii)* histamin, agmatin, putresin ve tiramin üreticisi *Enterococcus* spp. izolatları tespit edilmiştir. Çalışmada toplam 39 adet ev yapımı peynir örneği analize alınmış olup; selektif besi ortamında tipik morfolojiye sahip kolonilerden rastgele seçilerek, 99 adet muhtemel *Enterococcus* spp. suşu izole edilmiştir. Gram (+), tek ya da kısa zincirler halinde kok ya da kokobasil morfolojisine sahip, katalaz (-) izolatların; kısmi karakterizasyon sonuçlarına göre 2 adetinin (BE-2/7 ve BE-11/33) *Enterococcus* spp. cinsine dahil olmadığı belirlenmiştir. Aminoasit dekorboksilaz aktivitesi, prekürsor aminoasit olarak ornitin (putresin), histidin (histamin), arjinin (agmatin) ve tirozin (tiramin) içeren dekarboksilaz broth ortamları kullanılarak belirlenmiştir. *Enterococcus* spp. izolatlarının hiçbirinin putresin üreticisi olmadığı; buna karşılık hepsinin histamin ve agmetin üreticisi olduğu tespit edilmiştir. Bununla birlikte 19 izolatın (BE-1/3, BE-3/12, BE-3/15, BE-10/30, BE-11/31, BE-20/50, BE-20/52, 62, 64, ÇE-2/70, EE-2/76, EE-3/78, EE-3/79, BE-4/85, BE-26/92, BE-27/96, BE-27/97, BE-28/98 ve BE-28/99) tiramin üreticisi olduğu belirlenmiştir. Elde olunan sonuçlar halk sağlığı ve gıda güvenliği açısından değerlendirildiğinde, Bayramiç (Çanakkale) ilçesinde tamamen kontrolsüz koşullarda üretilerek tüketilen ve/veya satışa sunulan peynirlerin olası biyojen amin üreticisi *Enterococcus* spp. türlerinin prevalansının yüksek olduğunu ortaya koymaktadır.

Anahtar Kelimeler: Çanakkale/Bayramiç, Peynir, *Enterococcus* spp., Biyojen amin

Abstract

This study conducted comprehensive molecular docking analyses to evaluate the binding potential of newly proposed ligand candidates targeting the Ecdysone Receptor/Ultraspiracle (EcR/USP) heterodimer complex, a key regulator of insect development and metamorphosis[1]. Since EcR/USP is a critical target in the development of insect growth regulator–based pesticides[2], computational elucidation of ligand–receptor interactions constitutes an essential preliminary step in rational drug and pesticide design. In this context, five candidate ligands (**1a**–**1e**), planned for future synthesis, were subjected to AutoDock-based calculations using the crystal structure of the EcR/USP complex (PDB: 2R40)[3]. The protein structure was optimized through the addition of polar hydrogen atoms and assignment of Gasteiger charges, while the ligands were incorporated into the docking workflow following energy minimization and conversion to three-dimensional conformations. Grid box parameters were configured to fully encompass the binding pocket. The resulting binding affinity values indicated that ligand–receptor interaction strengths ranged from –5.8 to –7.4 kcal/mol. The strongest affinity was observed for ligand **1e** (–7.4 kcal/mol), which was stabilized by a synergistic combination of hydrogen bonds, pi–pi and pi–sigma interactions, and extensive hydrophobic contacts. The other ligands also established diverse binding motifs, including hydrogen bonds with arginine, aspartate, and glutamine residues; pi-cation interactions with positively charged amino acids; and alkyl/pi-alkyl interactions with apolar residues. The findings demonstrate that ligand **1e** represents a particularly promising binder for the EcR/USP target and stands out as a strong candidate for subsequent biological evaluation. The outcomes of this study provide a computational foundation for the development of new pesticide candidates based on insect growth regulation and offer critical insights to support the transition into experimental validation.

Endothelial dysfunction in type 1 diabetes and therapeutic targets

Abstract

Type 1 diabetes mellitus (T1DM) is characterised by autoimmune destruction of pancreatic β cells, leading to insulin deficiency and chronic hyperglycemia. T1DM is increasingly impacting adults and has a substantial cardiovascular burden, while being previously thought of as a childhood illness. There is growing evidence that endothelial dysfunction is an early, key process that drives both micro- and macrovascular disease, rather than only a downstream result of more advanced problems. Mechanisms: Endothelial dysfunction in type 1 diabetes is caused by a complex interaction of structural, metabolic, and inflammatory variables. Excessive reactive oxygen species (ROS) and oxidative stress are caused by mitochondrial dysfunction induced by chronic hyperglycemia. This setting reduces endothelium-dependent relaxation by decreasing nitric oxide (NO) bioavailability, a vital vasodilator. Additionally, because it promotes oxidative stress and hinders vascular repair mechanisms, glycemic fluctuation is more harmful than continuously elevated glucose levels. Cellular and Systemic Impact: Reduced circulating endothelial progenitor cells (EPCs), particularly the $CD34^{+}KDR^{+}$ subgroup, indicate early vascular ageing and compromised vascular repair ability at the cellular level. However, disruption of the endocannabinoid-microbiota axis leads to endothelial barrier failure, which makes it easier for immune cells to infiltrate target tissues and exacerbates systemic autoimmunity. Furthermore, endothelial dysfunction in diabetic vasculopathy has been linked to changes in red blood cell activity and extracellular vesicles produced from erythrocytes. In conclusion, endothelial dysfunction is a critical therapeutic target for the treatment of type 1 diabetes. Future treatments for T1DM patients should primarily focus on lowering oxidative stress, stabilising glycemic control to reduce unpredictability, and activating endothelial repair pathways to enhance long-term cardiovascular outcomes.

Abstract

Type 1 diabetes mellitus (T1DM) is an autoimmune-mediated disease of islet β-cell destruction and has traditionally relied on exogenous insulin to achieve glycemic control. In recent years, interdisciplinary research has spurred the clinical translation of several novel treatment strategies, particularly immunomodulation, β-cell replacement, and targeted insulin delivery. Immunomodulatory therapy: Immunosuppressants, represented by the anti-CD3 monoclonal antibody. Teplizumab, were approved by FDA as the first T1DM drug with disease-modulating effects. This drug can delay the progression of patients from subclinical to clinical onset and is expected to extend phase 2 progression by approximately 3 years. Additionally, other monoclonal antibodies and cell therapies targeting autoimmune mechanisms are also in clinical trials aimed at restoring immune tolerance. On the other hand, gene-modified islet cells used CRISPR-Cas12b to knock out immune-related genes and overexpress CD47, resulting in long-term survival of allogeneic islet cells in immunosuppressant-naive patients and significant improvements in glycemic control. Pluripotent stem cell-derived islet cells (VX-880, VX-264) which are stem cell-derived islet organoids, developed have entered phase I/II clinical trials and can restore islet function with gene editing or immunoprotection devices. A clinical case of chemical reprogramming of induced pluripotent stem cells (CiPS) demonstrates the potential of stem cell regenerative transplantation for the functional treatment of T1DM. Smart insulin delivery a closed-loop insulin pump system automatically adjusts insulin infusion using real-time continuous glucose monitoring (CGM) and algorithms, resulting in a significant increase in blood glucose time within the target range (TIR) and a significant reduction in hypoglycemic events, which has been validated in multicenter studies both domestically and internationally. In conclusion, key future challenges include increasing the large-scale production of cell resources, mitigating the safety risks of gene editing, and improving the algorithm reliability of closed-loop systems.

Bioacoustic Differentiation of Advertisement Calls between the cf. Bedriagae Water Frog Lineage (Genus: *Pelophylax*) in Central Anatolia and the Cilician Water Lineagae in the Frog Çukurova Plain in Türkiye

Mehmet Bera Demirkan[1*] (ORCID: https://orcid.org/0009-0008-3970-7368), Ulaş Birdal[1*] (ORCID:https://orcid.org/0009-0001-0653-5159),

Abstract

Anurans are among the most vocally active vertebrate groups, and the sounds they produce serve many purposes including territory marking, mate attraction, and danger detection. Among these, the advertisement call is highly species-specific and plays a key role in forming pre-mating reproductive barriers. The Anatolian water frog complex (genus *Pelophylax*) contains many genetically, phylogenetically differentiated but morphologically indistinguishable cryptic evolutionary lineages. Since water frogs are notoriously difficult to differentiate morphologically and also include many hybrid forms, mating calls become one of the most direct indicators of species boundaries, as vocal sac morphology and call structure co-evolve with lineage divergence. For this reason, bioacoustics analyses provide an important complementary dataset for verifying genetic differentiation among distinct lineages. In this study, 36 males from Ankara and Bolu (cf. bedriagae lineage) and 17 males from Adana and Hatay (Cilician lineage) were analyzed. The analysis was conducted using min 10-minute sound recordings from each collected directly from nature. The process of call segmentation and individual identification were performed within the framework of Raven Pro, utilising expert assistance and adhering to four main interaction criteria: sufficient spatial separation, clear positional distinction, non-overlapping call sequences, and consistency of parameter stability across calls. Since natural recordings inevitably include multiple overlapping individuals, correct individual assignment was essential. After individual calls were classified, the temporal and spectral variables of advertisement calls were extracted, and ANCOVA was performed with water temperature included as a covariate. The results showed that when the impact of temperature was statistically regressed out of the data, analyses of advertisement call data exhibited clear differentiation between the cf. bedriagae and Cilician lineages. The acoustic distances reflected both the known genetic structure and the geographic separation patterns of cf. bedriagae populations (Gediz, Kızılırmak and Yeşilırmak basins) and the Cilician populations (Çukurova basin, Adana–Hatay). Importantly, these lineages were successfully distinguished using field-recorded calls rather than laboratory-controlled recordings. This demonstrates that bioacoustics in the natural environment is sufficient to resolve divergence between these closely related water frog lineages. This study provides valuable data on whether genetic differentiation in Anatolian water frog lineages is mirrored at the bioacoustic level and contributes to understanding pre-mating isolation mechanisms in these cryptic *Pelophylax* lineages.

Özet

Demir, biyoaktif metal iyonlarından birisidir ve enerji üretimi, O_2 taşınması, enzim katalizi, DNA-RNA sentezi ve onarımı gibi birçok fizyolojik ve patolojik süreçte önemli rol oynar [1, 2]. Bu nedenle, canlı sistem için vazgeçilmez ve temel elementlerden birisidir. Vücutta Fe(III) iyonlarının eksikliği veya fazlalığı çeşitli hastalıklara neden olabilir. Demir, biyolojik sistemlerde oksijen taşıyıcısı görevi görür. Eksikliği durumunda hücrelere düşük oksijen gider ve bu durum anemi, diyabet, karaciğer ve böbrek hasarı gibi birçok sağlık sorununa neden olabilir [3- 5]. Öte yandan, vücuttaki aşırı demir miktarı, Alzheimer, Huntington ve Parkinson hastalıkları, akciğer, pankreas, kalp gibi organların fonksiyonlarının bozulması ve çeşitli kanser türleri gibi birçok ciddi hastalığa yol açabilir [6, 7]. Bu nedenle, sudaki demir iyonlarının seçici, hassas ve güvenilir bir şekilde belirlenmesi son derece önemli bir gerekliliktir. Literatürde Fe(III) iyonlarının tespiti için alev atomik absorpsiyon spektrometrisi (FAAS), kolorimetri, indüktif eşleşmiş plazma kütle spektrometresi (ICP-MS), indüktif eşleşmiş plazma optik emisyon spektrometresi (ICP-OES), yüksek performanslı sıvı kromatografisi (HPLC) gibi birçok seçici, hassas ve hızlı belirleme yöntemi rapor edilmiştir. Ancak bu yöntemlerin pahalı ekipman gereksinimi, operasyonel karmaşıklık, uzun hazırlık süresi ve karmaşık numune hazırlama gibi bazı dezavantajları vardır [8]. Diğer geleneksel analitik tekniklerle karşılaştırıldığında, floresans sensörler, yüksek duyarlılığı, uygulama kolaylığı, kısa analiz süresi ve yüksek seçiciliği ile Fe(III) tayini için çok daha avantajlı bir yöntem olarak öne çıkmaktadır. Bu çalışmada, sulu ortamdaki Fe(III)' ün tayini için yeni bir rodamin-B bazlı floresans membran sensör hazırlanmış ve karakterize edilmiştir. Membranın karakterizasyonu, Fourier dönüşümlü kızılötesi (FTIR) spektroskopisi ve taramalı elektron mikroskobu (SEM) kullanılarak ile gerçekleştirilmiştir. Hazırlanan membranın floresans sensör özelliği floresan spektroskopisiyle değerlendirilmiştir. Sensörün çalışma aralığı, pH etkisi ve cevap süresi gibi çalışma parametreleri sistematik olarak incelenmiştir. Geliştirilen rodamin-B bazlı membrane sensör, sulu ortamdaki Fe(III)' ün tayini için pratik, hassas, seçici ve yeniden kullanılabilir bir alternatif sunmaktadır.

Anahtar Kelimeler: Fe (III) tayini, optik sensör, floresans.

Design of an Assay for Detecting Ehlers-Danlos Syndrome in Bengal Cats via Enzymatic Digestion

Mehmet Cevat Temizkan[1*] (ORCID: https://orcid.org/my-orcid?orcid=0000-0002-4353-6759)

[*1]Yozgat Bozok University, Faculty of Veterinary Medicine, Department of Genetics, Yozgat, TÜRKİYE.

*Corresponding author e-mail: m.cevat.temizkan@yobu.edu.tr

Abstract

Ehlers-Danlos syndrome is a connective tissue disorder characterized by skin hyperextensibility and joint laxity observed in various animal species. In Bengal cats, this condition results from an autosomal dominant deletion in the *COL5A1* gene. The variation involves a 22-nucleotide deletion spanning the last 7 nucleotides of exon 1 and the first 15 of intron 1, causing a splicing defect. Using OMIA, NCBI GenBank, and Ensembl data (OMIA ID: 002165-9685, 1464; NCBI: XM_023242950.2:c.115_121+15del; Ensembl: ENSFCAT00000060880.2), we investigated the feasibility of detecting this region via enzymatic digestion. We identified that primers Forward: CCCATGACTTCCTAGAGCGC and Reverse: GAGGCAAACCCAAGAACAACTG, combined with BfuAI/BspMI or BseYI enzymes, can detect the disease. The designed primers are specific to the target region and bind effectively to all *COL5A1* transcripts except minor ENSFCTT00005002702.1. However, due to high primer-dimer potential, optimization of the annealing temperature is required. Digestion of the wild-type allele with BfuAI/BspMI should generate 535 bp and 214 bp fragments, while BseYI should produce 515 bp and 234 bp fragments. Conversely, in mutant cats, the 22-bp deletion prevents digestion, resulting in a single 727 bp band. These results were confirmed via NebCutter restriction digestion simulations. This method allows for a preliminary diagnosis without immediate DNA sequencing. Unlike expensive sequencing equipment rarely found in routine clinics, this primer-enzyme combination offers rapid and reliable results. Although confirming positive samples via sequencing is recommended, eliminating the need to sequence negative samples provides a practical advantage for veterinary practitioners.

Comprehensive genome analysis and various functional attributes of a potential *Enterobacter bugandensis* isolated from Türkiye

Cumhur Avşar (Orcid: https://orcid.org/0000-0002-4095-0022)

Department of Biology, Sinop University, Sinop, Türkiye

Corresponding author e-mail: cumhur.avsar@gmail.com

Abstract

Research on *Enterobacter bugandensis*, a member of the *Enterobacter cloacae* complex (ECC) that has recently attracted attention within this group and is considered the most pathogenic species in the group, is prominent. Recent confusion in the identification of ECC group members has made it difficult to identify dangerous members within the group. Supported by Sinop University, the BAP unit with code FEF-1901-25-005, this work aims to determine the antibiogram analysis, IAA, ACC deaminase, siderophore, biofilm production, Bradford protein content, and phosphate-solubilizing activity of a strain isolated from rice soil and identified as *Enterobacter bugandensis* based on 16S rRNA and whole-genome sequence analysis. Additionally, boron and arsenic resistance and intracellular boron accumulation were determined. The definitive identification of this strain through whole-genome analysis and the annotation of its genome with detailed gene information were presented using programs such as Proksee and KEGG. It was determined that this strain does not possess phosphate solubilization and ACC deaminase activity, with IAA activity at 5.7±0.65 µg mL^{-1}, siderophore production at 86.3±6.1 µmol L^{-1}, and Bradford protein content at 391.2±7.12 µg mL^{-1}. In addition, it was observed that it grew at a boron concentration of 100 mM, did not grow in the presence of As (III), but had an MIC value of 22 g/L for As (V). Furthermore, this strain was found to have intracellular boron accumulation (0.23±0.02 mg/L). However, this strain was observed to be resistant to many different antibiotics that inhibit cell wall and protein synthesis (ampicillin, cefoxitin, aztreonam, linezolid, clindamycin, etc.). The genome size was found to be 4.7–4.9 Mbp, similar to typical *E. bugandensis*, with a GC content of ~55%, 1262 CDS, 12 tRNA, 15 ncRNA, and 14 regulatory RNA. Furthermore, based on genomic analysis, this strain was found to possess multidrug resistance (MDR), carry *IncFII*(*pECLA*) and *IncR* plasmids (containing numerous *tra*, *trb*, *rep*, *mob*, and conjugal-transfer genes), and have the presence of 3 prophages, which typically carry efflux pumps, virulence factors, accessory genes, and stress adaptation genes. These phages are known to contribute to the genomic evolution of *E. bugandensis*. Furthermore, CRISPRCasFinder analysis indicates the absence of CRISPR/Cas loci, suggesting that this strain is more susceptible to plasmid acquisition and consistent with the presence of numerous ARGs and prophages. Additionally, the genomic analysis of this strain supports the phenotypic characteristics tested.

Keywords: *Enterobacter bugandensis*, MDR, CRISPR-CAS, prophage, genome analysis

Özet

Lipopeptitler (LP) amfifilik özellikleri sayesinde gösterdikleri antibakteriyel ve antifungal özellikleriyle tarım, gıda, kozmetik, tıp ve biyoremediasyon alanlarında alanlarda sıklıkla kullanılmaktadır. Günümüzde LP'lerin üretilmesinde *Bacillus* ve *Pseudomonas* suşları başta olmak üzere 11 farklı mikroorganizma kullanılmaktadır. Bu mikroorganizmalar arasında genel olarak güvenli (Generally Recognized As Safe, GRAS) kabul edilen *Bacillus* suşları kullanılarak, LP üretiminin uygun maliyetli koşullarla gerçekleştirilmesi kritik önem taşımaktadır. Siklik yapıda olan itürin ve sürfaktin lipopeptidlerinin üretilmesi için 3 farklı *B. subtilis* suşunun uygun maliyetli üretim ortamında geliştirilmeleri gerçekleştirilmiş ardından ortamdan siklik lipopeptidlerin (CLP'lerin) ekstraksiyonu asit degradasyon-metanol yöntemiyle yapılmıştır. Elde edilen CLP'lerin miktarları yüksek performanslı sıvı kromatografisiyle (HPLC) kromatografik olarak tespit edilmiş, uygun maliyetli üretim ortamında *Bacillus* spp.'nin ulaştığı canlı hücre sayıları dökme plaka yöntemiyle incelenmiş sonuçlar koloni oluşturan birim (kob)/ml olarak belirlenmiştir. Elde edilen sonuçlara göre, *Bacillus subtilis* EGE-B-36.5 suşu itürin üretimi açısından açık ara öne çıkmaktadır (3,777±0,946 mg/ml), diğer iki suş (EGE-B-1.19 ve EGE-B-3.P.5) ise oldukça düşük ve benzer itürin değerlerine sahiptir (sırasıyla 0,071±0,007 ve 0,071±0,005 mg/ml). Sürfaktin üretiminde ise EGE-B-1.19 suşu en yüksek değere (1,216±0,096 mg/ml) sahip olup, EGE-B-36.5 ve EGE-B-3.P.5 suşları sırasıyla 1,09±0,231 mg/ml ve 0,973±0,082 mg/ml ile onu takip etmektedir. Canlı hücre sayısı açısından ise EGE-B-1.19 suşu ($1,4x10^9$ kob/ml) diğerlerine göre çok daha yüksek hücre yoğunluğuna sahiptir. EGE-B-36.5 ve EGE-B-3.P.5 suşları ise sırasıyla $3,3x10^8$ ve $2,4x10^8$ kob/ml canlı hücre sayısı ile daha düşük yoğunluk göstermiştir. Çalışma sonucunda GRAS *B. subtilis* EGE-B-36.5 suşunun uygun maliyetli üretim ortamında itürin ve sürfaktin üretimi için potansiyel bir aday olduğu belirlenmiştir.

Anahtar Kelimeler: Lipopeptid, sürfaktin, itürin, HPLC, *Bacillus*, GRAS

Abstract

A chloro-aza acyclovir analogue, ^{1}N-(5'-diethylamino-3'-hydrochloro)-6-aminouracil, was synthesized using 6-aminouracil as a nitrogen base. Dichloroethylamine was used as an open chain and dissolved in DMF. Sodium carbonate was employed as an economical catalytic agent. The reaction yielded a yellow crystalline powder. Structure identification was achieved through comprehensive spectroscopic characterization, including IR spectroscopy, ^{1}H-NMR, ^{13}C-NMR, DEPT-135, COSY-NMR, HMQC, and EI-MS.

Keywords: aza acyclovir analogue, 6-aminouracil, diethanolamine.

Abstract

The genus *Cirsium*, belonging to the Asteraceae family, comprises more than 250 species distributed across Europe, North Africa, Asia, and North and Central America. In the flora of Türkiye, this genus is represented by a total of 64 species classified under three sections [1]. Species of *Cirsium*, commonly known as "thistles," are reported to exhibit various pharmacological properties, including hepatoprotective, antioxidant, anticancer, antimicrobial, and anti-inflammatory activities [2]. In this study, the cytotoxic activities of n-hexane (CCH), dichloromethane (CCD), and methanol (CCM) extracts obtained by percolation from aerial parts of *Cirsium ciliatum* subsp. *szovitsii* were evaluated on MCF-7 and fibroblast cell lines using the MTT assay. Additionally, the effects of extracts on cell viability and their potential wound-healing properties were investigated, while their antimicrobial activities against various microorganisms were assessed using agar well diffusion and microdilution (MIC) methods. According to the results, CCH extract markedly decreased MCF-7 cell viability (24.35 ± 3.98%), whereas CCM extract significantly enhanced fibroblast viability. Both CCH and CCM extracts exhibited antimicrobial activity against tested microorganisms, with MIC values ranging between 0.31 and 0.63 mg/mL. Considering their biological profiles, CCM extract appears to be a promising wound-healing candidate, while CCH extract stands out as a potential anticancer agent. The phenolic composition of CCM extract was analyzed by HPLC-DAD, revealing the presence of chlorogenic acid and apigenin 4-O-neohesperidoside. Isolation studies aimed at identifying the active constituents of CCH extract are currently ongoing.

Keywords: *Cirsium*, cytotoxicity, antimicrobial activity, wound healing, HPLC-DAD

Abstract

Olive pomace, a by-product generated during olive oil production, is generally considered a low-value product despite its high phenolic compound content. The literature indicates that olive pomace is rich in hydroxytyrosol and its derivatives and exhibits potent antioxidant properties (Alu'datt et al., 2017; Yılmaz & Gökmen, 2020). The aim of this study is to obtain a phenolic-rich extract from olive pomace (OP), determine the antioxidant capacity of the extract, and preliminarily evaluate its potential to support wound healing by integrating it into a topical cream formulation. After drying and grinding the olive pomace samples, an ultrasonic-assisted extraction method using ethanol was applied. This is consistent with previous studies showing that ultrasonic extraction increases phenolic yield (Ameer et al., 2017). Total phenolic content was determined using the Folin–Ciocalteu method, and antioxidant activity was analysed by DPPH inhibition. The strong radical scavenging capacity of phenolics derived from olive pomace has been previously reported in the literature (Obied et al., 2005). Antioxidant analyses revealed that the extract inhibited the DPPH radical by over 70%. These results are consistent with the literature regarding the biological activity of olive pomace polyphenols (Alu'datt et al., 2017). Additionally, in the preliminary animal model evaluation, it was found that epithelialisation occurred more rapidly in groups treated with cream containing the extract, consistent with previous studies reporting that polyphenols support wound healing (Rodriguez-Luna et al., 2019; Şakul AA et al.,2023).
This study demonstrates that olive pomace extract can be used in dermatological-cosmetic formulations containing natural active ingredients due to its antioxidant potential on wound-healing effect. Herein, incisional and excisional wound model is applied in BALB/c mice and further wound healing processes are observed (Şakul AA et al.,2023). Therefore, the study offers a sustainable approach to converting industrial waste into high-value products.

Keywords: sustainability, olive pomace, antioxidant activity, incisional and excisional wound model, BALB/c mice.

Abstract

Ethoprophos is an organophosphate pesticide widely used in agriculture. It poses significant environmental and health risks due to its neurotoxic effects and persistence in soil and water. Therefore, the accurate determination of trace concentrations is essential to evaluate its potential impact. In this study, a biosensor was developed for the trace-level detection of the pesticide ethoprophos. The limit of detection (LOD) and limit of quantification (LOQ) for the determination of ethoprophos using the developed biosensor were calculated to be 1.67×10^{-10} M and 1.26×10^{-9} M, respectively. The analytical performance of the biosensor was validated through recovery experiments in pineapple samples, yielding a relative error of 5.33% and a relative standard deviation (RSD) of 3.62%. These findings demonstrate the biosensor's high sensitivity and reliability, highlighting its potential application in routine monitoring of pesticide residues in food products. Moreover, the approach provides a rapid and cost-effective alternative to conventional analytical techniques. This contributes to improved food safety and environmental protection.

Keywords: Biosensor, ethoprophos, pesticide, voltammetry.

An integrated multi-omics framework for robust MSI detection in colorectal cancer

Abstract

Colorectal cancer (CRC) is one of the leading causes of cancer-related death worldwide and represents a heterogeneous group of tumors. Microsatellite instability (MSI) is a clinically important biomarker in CRC, helping identify patients who may benefit from immunotherapy and offering insight into disease behavior. Although PCR and immunohistochemistry are frequently used to identify MSI, they are not always sensitive enough and can produce ambiguous results. For this reason, multi-omic approaches that integrate broader molecular information are becoming increasingly important for achieving a more accurate and reliable assessment of MSI. Next-generation sequencing–based methods have expanded MSI testing, yet many still rely on a single type of molecular data and typically neglect the challenges of incomplete datasets encountered in clinical practice. To address these limitations, this study proposes a multi-omics framework that integrates RNA expression, DNA methylation, and WES-derived mutational features. This approach aims to describe MSI biology more clearly by considering immune-related gene expression changes along with methylation patterns observed in MSI-H tumors. This overview outlines the rationale for building a reproducible diagnostic model with improved sensitivity, precise calibration, and robust performance even in the presence of missing data modalities. The proposed integrated workflow has the potential to improve clinical utility through decision curve analysis, optimize patient stratification, and contribute to the development of more robust biomarker-guided diagnostics in colorectal cancer.

Abstract

Microorganisms residing in the human gut microbiota establish symbiotic interactions with their host and contribute to the regulation of numerous physiological processes, including digestion, immune modulation, and the maintenance of intestinal barrier integrity. The therapeutic effects of these living microbes, known as probiotics, on human health have been widely recognized, leading to the development of targeted probiotic formulations in various dosage forms within the pharmaceutical sector and their incorporation into clinical practice. Recently, the concept of postbiotics, defined as inactivated microbial cells, their components, and metabolites produced by microorganisms, has attracted growing interest and has emerged as a promising focus for research and applications, particularly in the pharmaceutical industry. Compared with probiotics, postbiotics offer advantages such as greater shelf-life stability, improved convenience in storage and formulation, and a lower risk of adverse effects while still providing health-promoting benefits for both adults and children. Beyond their antimicrobial properties, postbiotics are increasingly considered as promising therapeutic candidates for a variety of noncommunicable diseases. In this regard, this study aims to provide a concise overview of the classification, production technologies, and mechanisms of action of different postbiotics, and to present their biological activities reported in *in vitro* and *in vivo* studies, thereby highlighting their potential as novel functional agents in the management of chronic diseases.

Abstract

The enantiomers of 1-phenylethanol, an important secondary alcohol, are used in many industries, such as pharmaceuticals, agriculture, food and cosmetics. Furthermore, the search for reliable, environmentally friendly green solvents to replace traditional solvents has recently increased. The aim of this study was to produce 1-phenylethanol with enantiomeric purity using an enzymatic kinetic resolution method in a green solvent environment. Dimethyl carbonate, an organic carbonate, was used as the green solvent. Novozyme 435 (an immobilised lipase) was used as the lipase and vinyl acetate was used as the acyl donor. After the reaction, the samples were analysed by HPLC using a chiral column. The optimum reaction conditions in dimethyl carbonate were determined using the response surface method (RSM). Furthermore, the advantageous properties of dimethyl carbonate, such as low ecotoxicity, biodegradability, low cost and high ee_s and conversion, suggest that it could replace traditional solvents.

Keywords: 1-phenylethanol, green solvent, dimethyl carbonate, enzymatic kinetic resolution, enantioselectivity, RSM.

Abstract

Zinc oxide nanoparticles (ZnO NPs) were synthesized via a simple, eco-friendly precipitation method utilizing a reducing agent derived from pomegranate (*Punica granatum*) peel extract. X-ray diffraction (XRD) analysis confirmed the successful formation of ZnO with a hexagonal crystal structure and an average crystallite size of less than 30 nm. Scanning electron microscopy (SEM) revealed distinct quasi-spherical and nanorod-like morphologies, while energy-dispersive X-ray spectroscopy (EDX) confirmed the presence of zinc and oxygen in the nanoparticles. Diffuse reflectance spectroscopy (DRS) indicated significant UV activity, with a band gap of 3.25 eV. The photocatalytic efficiency of the synthesized ZnO NPs was evaluated based on their ability to degrade diclofenac sodium (DCF) under UV-LED irradiation, achieving pollutant removal rate exceeding 99%.

Keywords: Diclofenac, Green synthesis, *p*-nitrophenol, Photocatalytic degradation, Pomegranate peel extract, *Punica granatum*, ZnO.

Abstract

Nephrotic syndrome (NS) is a glomerular disorder characterized by heavy proteinuria, hypoalbuminemia, edema and hyperlipidemia, and remains a major clinical challenge due to its heterogeneous etiology and variable treatment response. Classical biomarkers such as urinary protein excretion, serum albumin, creatinine, blood urea nitrogen (BUN) and lipid profile are routinely used for diagnosis and monitoring; however, their limited sensitivity and specificity restrict their ability to differentiate NS subtypes or detect early renal injury. This study summarizes current advances in molecular biomarkers that complement traditional parameters and enhance diagnostic precision in NS. Anti-Phospholipase A2 Receptor Antibody (Anti-PLA2R) and Anti-Thrombospondin Type-1 Domain-Containing 7A Antibody (anti-THSD7A) antibodies have markedly improved the noninvasive diagnosis of primary membranous nephropathy (MN), with anti-PLA2R detected in 70–80% of MN cases, while anti-THSD7A identifies a subset of PLA2R-negative patients. Recently defined podocyte-associated biomarkers including Neural Epidermal Growth Factor–Like 1 (NELL1), Exostosin-1 / Exostosin-2 (EXT1/EXT2), Semaphorin-3B, Protocadherin-7 and Wilms' Tumor 1 (WT1) provide novel opportunities for subclassification of NS and prognostic evaluation. Tubular injury and inflammation-related markers such as Neutrophil Gelatinase–Associated Lipocalin (NGAL), β2-microglobulin, D-dimer, α-1 antitrypsin and Cluster of Differentiation 80 (CD80) demonstrate potential for tracking disease activity and predicting therapeutic response. Furthermore, urinary exosomal microRNAs and circular RNAs represent promising noninvasive biomarker candidates with high clinical translational value. Overall, emerging biomarker panels combining serological, genetic and proteomic indicators offer superior diagnostic accuracy compared to isolated parameters and may reduce the need for invasive renal biopsy. Standardization of analytical methods and large-scale prospective validation studies are essential for integrating these biomarkers into routine nephrology practice.

Abstract

In fiber-reinforced epoxy matrix composites, the fiber material can be synthetic or natural. Examples of synthetic fiber materials include glass, aramid, and carbon. Although these composites have advantages in terms of high mechanical properties, they have disadvantages such as high production costs and difficulties in recycling. Composites produced using natural plant-based fibers such as hemp, jute, flax, and banana peel are low in cost, but their biggest disadvantage is their low strength. Various methods are currently being used to improve this disadvantage. These include using different weave types, using more than one fiber material simultaneously, applying different weave types, and improving the fiber-matrix interface. In our study, biocomposites were produced using both natural and hybrid fiber materials to improve the properties of composite materials. Hemp, jute, and flax were used as natural fiber materials. In the first phase of our study, composites made from the same type of fiber material were produced. Biocomposites were then combined to produce three different hybrid structures. Thus, nine different fiber material groups were created, considering both single-type and hybrid structures. In the second stage, biocomposites were produced using different weaving methods. Plain, twill, and panama were used as weaving methods. A total of 27 different natural fiber fabrics were obtained by using three different textures, nine different single-hybrid and different fiber types mentioned above. In the third stage, the produced woven were combined with a bio-specific epoxy matrix material using a vacuum infusion method to produce biocomposite. In the final stage of our study, internal structure analyses were performed using stereomicroscope and scanning electron microscope (SEM). Our aim in the microstructure analysis was to examine the fiber-matrix distribution, the structure and orientation of the fibers and the interface formation.

Abstract

Glioblastoma is the most common primary malignant tumor of the central nervous system. Although treatment methods such as chemotherapy, radiotherapy, and immunotherapy are available, these therapies have various adverse side effects and limitations. For this reason, plant-based therapeutic approaches have recently gained attention. Honokiol, a phenolic plant compound, is derived from the seeds, roots, stems, and leaves of species belonging to the Magnolia genus. Honokiol has demonstrated strong anticancer potential through its ability to modulate key processes such as metastasis, invasion, and apoptosis. However, its clinical application is restricted by challenges such as low solubility, poor bioavailability, and rapid metabolism, thereby highlighting the necessity for a nanoparticle-based delivery system. To reduce rapid drug metabolism and support penetration through the blood–brain barrier, honokiol was encapsulated into poly(lactic-co-glycolic acid) (PLGA) nanoparticles in this study. Honokiol-loaded PLGA nanoparticles were synthesized using the single emulsion (o/w) solvent evaporation method. The particle size and PDI values of the synthesized nanoparticles were determined. The functional groups on the nanoparticle surface were analyzed using Fourier Transform Infrared (FT-IR) spectroscopy. The produced nanoparticles exhibited an average size of 196±2.4 nm, with a PDI value of 0.257±0.007. The reaction yield (RV) was determined as 48%, while the encapsulation efficiency (EE) was 74%, and the drug loading (DL) were 6.6%. According to the FT-IR analysis, the nanoparticles displayed characteristic PLGA features, confirming the successful encapsulation of honokiol. As a result of this study, Honokiol-loaded PLGA nanoparticles were successfully synthesized, and their physicochemical characterization was completed. In future stages, the in vitro anticancer activity of Honokiol-loaded nanoparticles on the U87MG glioblastoma cell line will be evaluated.

Özet

Sığır karkas ve et kalitesi, tüketici taleplerini karşılayan ürünler elde etmede kritik öneme sahiptir ve yüksek ekonomik değeri nedeniyle genetik ıslah hedeflerinde yaygın bir performans parametresidir. Modern genetik yaklaşımlar, karkas kalitesini etkileyen spesifik genlerin belirlenmesini sağlayarak ıslah programlarında etkin kullanımını desteklemektedir. Bu bağlamda; kas gelişimi, yağ metabolizması ve büyüme faktörlerini düzenleyen genler, karkas kalitesinin genetik temelini anlamak için kritik öneme sahiptir. Bu nedenle, leptin (*LEP*), insülin benzeri büyüme faktörü 1 (*IGF1*) ve miyojenik faktör 5 (*MYF5*) genleri sığırlarda karkas özelliklerini anlamak için temel adaylar olarak seçilmiştir. Bu çalışma, Holstein-Friesian ırkı erkek sığırlarda karkas ve et kalite özellikleriyle bu genlerin arasındaki ilişkiyi araştırmayı amaçlamıştır. Yüz üç sığır, PCR-RFLP yöntemi kullanılarak genotiplendirilmiştir. Ardından; bu genlerin canlı ağırlık, sıcak ve soğuk karkas ağırlığı, karkas randımanı, *musculus longissimus dorsi* alanı, Warner-Bratzler kesme kuvveti (WBSF), pişirme kaybı, soğutma kaybı, su tutma kapasitesi, karkas uzunluğu, göğüs genişliği ve et rengi parametreleri (*L*, a*, b**) ile ilişkileri incelenmiştir. Genlerin bireysel ve interaksiyon etkilerinin fenotipe yansımasının değerlendirmesinde GLM protokolü kullanılmıştır. Karkas ve et kalitesi arasındaki denge, Pareto-front yaklaşımı kullanılarak değerlendirilmiştir. Bireysel olarak incelendiğinde, *IGF1, MYF5* ve *LEP* genleri ile özellikler arasında anlamlı bir ilişki gözlenmemiştir (P >0,05). Ancak, *LEP* × *MYF5* interaksiyonu, canlı ağırlık, sıcak karkas ağırlığı ve soğuk karkas ağırlığı özellikleriyle anlamlı bir ilişki göstermiştir (P<0,05). Bu ikili interaksiyon, Holstein-Friesian sığırların karkas performansını önemli ölçüde etkileyebilecek bir epistatik örüntüyü ortaya koymuştur. Bildiğimiz kadarıyla, bu çalışma *LEP* × *MYF5* epistatik etkileşiminin sığır karkas performansı ile ilişkili olduğuna dair ilk kanıtı sunmaktadır. Standart et kalite parametreleri için karşılık gelen bir etkileşim tespit edilmemiştir. Bu bulgular, karkas verimini iyileştirmek için tek lokus etkilerinden ziyade, epistatik belirteç kombinasyonlarının seçim indekslerine ve eşleştirme planlarına dahil edilmesini desteklemektedir. Sonuçlar, sığır karkas ve et kalite özelliklerinin altında yatan gen-gen etkileşimlerinin bağımsız popülasyonlarda doğrulanması ve daha derinlemesine araştırılması için önemli bir motivasyon sağlamaktadır.

Abstract

The aim of this study is to evaluate the poisonous mushroom species commonly seen in Türkiye and the poisoning cases caused by these species in terms of their toxin structures, clinical symptoms and treatment approaches; and to draw attention to the risks they pose to public health. Morphological similarities between edible and poisonous mushrooms lead to serious poisoning cases that threaten public health. Consumption of wild mushrooms collected from nature, especially in spring and autumn months, can have fatal consequences due to species containing toxins such as amatoxin, gyromitrin, muscarin and orellanin. In this study, poisonous mushroom species commonly seen in Türkiye (*Amanita phalloides, Cortinarius orellanus, Gyromitra esculenta, Inocybe* spp. and *Clitocybe* spp.) and the poisoning cases caused by these species were evaluated in the light of current literature and case reports. Poisoning symptoms may occur with gastrointestinal, hepatotoxic, nephrotoxic or neurotoxic findings depending on the type of toxin. Early symptoms include nausea, vomiting and abdominal pain, while in the late period liver failure, kidney damage and neurological complications may be observed. Amanita phalloides poisoning in particular causes serious hepatocellular damage due to amatoxins inhibiting the RNA polymerase II enzyme. Early diagnosis, gastric lavage, activated charcoal application and supportive treatments are at the forefront of the clinical approach, and in some cases the use of antidotes such as silibinin and N-acetylcysteine is also recommended. Every year in Türkiye, dozens of people apply to hospitals due to mushroom poisoning, and unfortunately some lose their lives. This situation once again reveals the importance of raising public awareness, correct species identification and dissemination of toxicological analyses. In this context, the identification of poisonous mushrooms, understanding of toxins and development of effective treatment protocols require a multidisciplinary approach from both clinical and mycological perspectives.

Abstract

Today, cancer continues to be one of the most common causes of death worldwide. Conventional treatment methods such as chemotherapy, radiotherapy and surgery often lead to serious side effects and face problems such as tumor resistance. Therefore, interest in natural, safe and effective agents that can support cancer treatment is increasing day by day. In this context, medicinal mushrooms have significant potential. Medicinal mushrooms contain bioactive compounds that have been used in traditional medicine, especially in Asian countries, for centuries and whose effectiveness has been scientifically confirmed today. Species such as Ganoderma lucidum (Reishi), Trametes versicolor (Turkey tail), Lentinula edodes (Shiitake) and Inonotus obliquus (Chaga) contain many pharmacologically valuable compounds such as immunomodulatory polysaccharides (especially beta-glucans), triterpenoids, phenolic compounds and ergosterol derivatives. Various in vitro and in vivo studies have shown that these compounds suppress the proliferation of cancer cells, stimulate the apoptosis (programmed cell death) process, prevent metastasis and, in some cases, increase the effectiveness of chemotherapy drugs. It is also known that they strengthen the immune system and create a more effective immune response against the tumor. In particular, fractions such as PSK (polysacchiside-K) and PSP (polysacchiside-peptide), obtained from the Trametes versicolor mushroom, have entered clinical use as adjuvant agents in cancer treatments in Japan and China. However, the acceptance of such agents in Western countries is still limited and more clinical studies are needed. In conclusion, the use of medicinal mushrooms as complementary agents in cancer treatment is promising both at the cellular level and in clinical applications. However, more scientific data is needed to clarify issues such as standard dosage, reliability, interactions and long-term effects. Research conducted in this direction will both increase the quality of life of patients and further solidify the place of natural products in modern medicine.

Abstract

Exercise is a powerful biological stimulus that induces not only short-term physiological responses but also long-term molecular adaptations through epigenetic regulation. Among epigenetic mechanisms, DNA methylation plays a key role in regulating exercise-induced gene expression and maintaining cellular memory. However, the dynamic and nonlinear nature of these changes cannot be fully explained using traditional biological approaches alone. This study aims to develop a mathematical framework to model exercise-induced DNA methylation dynamics by integrating differential equation–based modeling with topological data analysis (TDA). DNA methylation levels before and after exercise are represented as time-dependent variables governed by differential equations. The model incorporates biologically relevant parameters, including DNA methyltransferase (DNMT) and ten-eleven translocation (TET) enzyme activities, as well as exercise intensity and duration. This enables a quantitative and continuous-time analysis of methylation dynamics in response to physical activity. To capture the complex and high-dimensional structure of epigenetic data, topological data analysis is employed as a complementary approach. TDA allows the identification of structural patterns and transitions in DNA methylation profiles that may not be detectable using classical statistical methods. Through topological features, exercise-induced epigenetic remodeling is analyzed in terms of data continuity and structural change. The main contribution of this study is the proposal of a hybrid mathematical model that combines dynamic differential equation modeling with topological characterization of epigenetic data. The results suggest that exercise can induce persistent epigenetic modifications contributing to molecular-level biological memory and that these processes can be effectively described using integrated mathematical approaches.

Abstract

In recent years, plant-derived bioactive compounds have attracted significant attention for their potential to prevent and manage cardiovascular diseases. Due to its high content of polyphenols and flavonoids, pomegranate peel represents a promising natural source of antioxidants. In this conducted study, the antioxidant properties of pomegranate peel extract and its potential effects on cardiovascular health are further discussed. The peel extract is highlighted for its role in neutralizing free radicals, reducing lipid peroxidation, and improving endothelial function, which may positively affect cholesterol metabolism. Furthermore, the potential of pomegranate peel as a sustainable, cost-effective raw material for the development of functional foods and nutraceutical products is further emphasized. Accordingly, this study aims to present the biomedical and biotechnological potential of pomegranate peel extract. This work is designed as a literature-based review that provides a scientific framework for future research in this field.

Chemical warfare agent recognition by using a practical mobile application

Ruşen Koray Eyison (Orcid:0000-0003-0151-6546)

University of Health Sciences, Institute of Defence Health Sciences, Ankara, Türkiye

Corresponding author e-mail: rusenkoray.eyison@sbu.edu.tr

Abstract

This study outlines the development of a mobile application designed to enable first responder personnel to rapidly and accurately recognize chemical warfare agents (CWAs) in accidents and disaster situations. In scenarios involving potential chemical exposure, timely diagnosis is critical for accurate triage, appropriate medical intervention, and personnel safety. The application integrates environmental assessment findings with a comprehensive database of CWA-specific clinical signs and symptoms. The core functionality of the application allows users to input observable environmental indicators - such as the presence, color, and odor of smoke of chemical agents - after which it identifies the potential toxic substance and provides first responders with the appropriate emergency medical approach. For example, the application may issue alerts noting that most toxic agents tend to settle to the ground (unlike cyanide), thereby warning personnel to use a full-face mask with the appropriate filter or to avoid working without gloves. Simultaneously, the application will guide first aid personnel through a systematic evaluation of patient signs and symptoms and, based on these, provide protocols for antidotal and supportive treatment. By utilizing these environmental and clinical data, the mobile application aims to identify the probable agent and enable first response teams to rapidly implement appropriate decontamination and initial medical management protocols. In doing so, it will contribute to improving both patient prognosis and operational safety.

Abstract

Urea [$CO(NH_2)_2$] is a key nitrogen-containing metabolite produced mainly in the liver through the urea cycle and excreted in body fluids such as blood and urine. Deviations in its concentration are clinically significant: levels below the normal serum range (8–20 mg/dL) may indicate liver dysfunction or nephritic syndrome, whereas elevated levels are associated with kidney failure, urinary tract obstruction, and disorders such as gastrointestinal bleeding. Conventional urea assays—calorimetry, gas chromatography, and spectrophotometry—require labor-intensive sample preparation and lack suitability for rapid or online monitoring. To address these limitations, in this study a low-cost, highly sensitive electrochemical biosensor was developed for the selective urea detection. A screen-printed electrode (SPE) was modified in situ with molecularly imprinted polymers (MIPs) synthesized in the presence of urea as the template molecule. After polymerization, the template was removed with an appropriate desorption agent to create specific recognition cavities. Electropolymerization was carried out in an aqueous solution containing 3-aminophenylboronic acid (APBA), pyrrole-3-carboxylic acid, and urea through cyclic voltammetry from 0 to +1.3 V at 100 mV s^{-1} for 10 cycles. Sensor performance was evaluated by cyclic voltammetry (CV) and electrochemical impedance spectroscopy (EIS) in 50 mM phosphate buffer (pH 7.0) with 10 mM KCl and 5 mM $[Fe(CN)_6]^{3-/4-}$. EIS used 180 mV DC with 10 mV AC over 10 kHz–0.05 Hz. Response difference of MIP and NIP sensors was determined by chrono-impedance (CI) at 200 mV and 100 Hz for 600 seconds. SEM and XPS, FTIR results confirmed surface morphology and chemical composition, respectively.
A non-imprinted sensor (NIP) was prepared in parallel to show negligible affinity toward urea, confirming the specificity of the MIP-modified sensor. The developed platform demonstrates the potential of MIP-based EIS sensors as a practical, selective, and rapid alternative to conventional urea assays for clinical diagnostics.

Abstract

This study investigated the effectiveness of natural deep eutectic solvents (NADES) for extracting bioactive compounds from rosehip (*Rosa canina L.*) fruits. Two formulations of citric acid–glycerol (1:4 and 1:2, with 30% water w/w) were compared to a conventional ethanol–water mixture. Total phenolic content (TPC) and antioxidant activities (DPPH, FRAP, CUPRAC) were assessed. The CA:Gly (1:4) system achieved the highest TPC (81.69 g GAE/kg dm), representing about a 75% increase compared to ethanol (46.81 g GAE/kg dm). In reducing-based assays, CA:Gly (1:2) reached the strongest FRAP activity (151.51 g TEAA/kg dm), roughly three times higher than ethanol (49.82 g TEAA/kg dm). CUPRAC activity was also enhanced in CA:Gly (1:4) (135.96 g TEAA/kg dm), exceeding ethanol (106.72 g TEAA/kg dm) by about 27%. In contrast, ethanol performed better in the DPPH assay (111.30 g TEAA/kg dm) compared with the NADES extracts (≈ 80 g TEAA/kg dm). Correlation analysis revealed a strong positive relationship between TPC and FRAP ($r = 0.936$, $p < 0.01$), suggesting that phenolics extracted by NADES were primarily responsible for the enhanced reducing capacity. These results highlight citric acid–glycerol NADES as efficient and eco-friendly extraction media that outperform ethanol in phenolic recovery, FRAP, and CUPRAC assays. Such extracts hold promise as natural antioxidants for use in food, nutraceutical, and cosmetic applications.

Abstract

The benzo[*d*]oxazole ring is one of the important heterocyclic ring systems in drug design due to its structural similarity to the purine analogues adenine and guanine bases, and its chemotherapeutic activities are thought to be mediated by inhibiting nucleic acid synthesis. The benzo[*d*]oxazole ring is also present in the structure of many drug molecules in clinical use: fenoxaprofen (anti-inflammatory), calcimycin (antimicrobial), clorzoxazone (muscle relaxant), caboxamycin B (antibacterial), pemafibrate (hyperlipidaemia), suvorexant (insomnia). To date, numerous benzo[*d*]oxazole derivatives have been synthesised and their pharmacological activities evaluated. However, it is known that the compounds reported in the literature have low activity and high side effect profiles, which limit the pharmacological effects of the drug molecules. Within the scope of this study, two new compounds derived from *N*'-(benzo[*d*]oxazol-2-yl)-4-substitutedbenzenesulphonylhydrazide were designed based on information from the literature. The synthesis and structural characterisation of the compounds designed within the scope of the study were carried out. For this purpose, in the first step, *o*-aminophenol is reacted with carbon disulphide to close the 2-mercaptobenzo[*d*]oxazole ring. In the subsequent step, the intermediate compound obtained is reacted with hydrazine hydrate to yield the 2-hydrazinylbenzo[*d*]oxazole compound. This compound is then reacted with suitable arylsulphonyl chloride derivatives in a basic medium to obtain the final compounds. The structures of the synthesised compounds were confirmed using ^{1}H- and ^{13}C-NMR and FT-IR spectral methods. The potential interactions of the two new candidate drug molecules, whose structures were confirmed, in the potential binding region were investigated by molecular docking studies on different protein target enzyme/receptor regions with reported anticancer properties in the literature. The compounds reported in the study were found to be potential human Topoisomerase II enzyme inhibitors.

Keywords: benzo[*d*]oxazole, sulfonylhydrazide, molecular docking

Abstract

The objective of this study was to compare the microflora profiles of gilthead sea bream (Sparus aurata) cultured in net cages and earthen ponds. For this purpose, gilthead sea bream samples were obtained from two different aquaculture facilities in Milas, Muğla—one utilizing net cages and the other earthen ponds—were transported in styropor boxes with ice to the laboratory of the Faculty of Fisheries at Muğla Sıtkı Koçman University. The fish were stored in a cold storage unit at +4°C for 16 days. During this storage period, samples were collected from both groups on intermittent days (0, 3, 6, 9, 12, 14, 15, 16) for the enumeration of mesophilic, psychrotrophic, lipolytic bacteria, and yeast-mold populations. Colonies grown on the culture media were isolated and identification was performed using Gram staining, oxidase testing, and API kits. The results indicated that microbial growth in net cage samples was slightly higher than in earthen pond samples during the initial days of storage. According to the findings, both Gram-positive and Gram-negative bacteria were present in the initially sterile fish flesh during the early stages of storage. However, as storage progressed, Gram-negative oxidase-positive bacterial species became dominant microflora compared to other bacteria. It was observed exhibited a broader spectrum of microorganisms in net cage-cultured fish. Evaluation of the results, based on identification using API kits, revealed that *Pseudomonas* spp. predominantly constituted the spoilage microflora in both culture systems. The study's findings highlighted the specific microorganisms that should be monitored in gilthead sea bream facilities based on storage duration. It was determined that the rearing conditions had minimal impact on the dominant spoilage microorganisms. It is suggested that future shelf-life studies could focus on developing methods to inhibit these bacterial species.

Protective effects of *Aloe vera* gel extract against cytotoxic, genotoxic, and physiological damage induced by nitric acid in *Allium cepa* cells

Aytül Uzun Akgeyik (https://orcid.org/ 0000-0002-5602-0524)

Yozgat Bozok University, Science and Technology Application and Research Center, Yozgat, Türkiye

Corresponding author e-mail: aytul.uzun@yobu.edu.tr

Abstract

This study was conducted using the *Allium cepa* L. test system to determine the possible physiological and cytogenetic effects of *Aloe vera* L. (ALV) leaf gel extract against the toxicity induced by nitric acid (HNO_3), a strong oxidizing agent. In terms of germination percentage, the ALV1 (10%) and ALV2 (20%) groups exhibited results similar to the control group. However, the marked decrease in germination percentage observed following HNO_3 exposure was significantly improved in the HNO_3ALV1 (10%) and HNO_3ALV2 (20%) combination groups, indicating the mitigating role of *Aloe vera* gel in suppressing toxic effects. Furthermore, compared with the HNO_3-treated group, significant increases in root length and fresh weight were observed in the HNO_3ALV1 (10%) and HNO_3ALV2 (20%) groups. With respect to the mitotic index (MI), the HNO_3ALV1 (10%) group showed a higher MI value than the HNO_3ALV2 (20%) group, suggesting that increasing the concentration of *Aloe vera* gel may exert an inhibitory effect on mitotic activity. Similarly, the frequency of chromosomal abnormalities and micronuclei (MN) was lower in the HNO_3ALV1 (10%) group compared to the HNO_3ALV2 (20%) group. Nonetheless, both combinations significantly reduced MN formation and chromosomal abnormalities compared to HNO_3 treatment alone, indicating a protective and antigenotoxic effect. In conclusion, the findings demonstrate that *Aloe vera* gel extract, when applied at appropriate concentrations, has the potential to act as a bioprotective agent by alleviating HNO_3-induced genotoxicity and physiological impairments in *Allium cepa* root meristem cells.

Keywords: Genotoxicity, *Aloe vera* L., HNO_3, *Allium cepa* L., Micronuclei.

Abstract

This study was conducted to investigate the survival of the probiotic *Saccharomyces boulardii* culture in filtered (F) and unfiltered (nF) extra virgin olive oils from the same season over a 90-day storage period, as well as the short-term effects of the culture on the fundamental quality indicators of olive oil. Within this scope, *S. boulardii* was inoculated into both autoclave-sterilized F and nF samples, both directly and after a pre-revitalization process. The samples, incubated at 25°C for four days, were then stored under olive oil storage conditions for three months. The growth of *S. boulardii* was monitored both at the end of the incubation and monthly over a period of 30 days during storage at 25°C. Microbial counts were performed by plating dilutions prepared with 5% (v/v) Tween-80 in 0.85% NaCl on Yeast Extract Glucose Chloramphenicol (YGC) Agar and incubating at 25°C for three days. The number of viable microorganisms was calculated as Log CFU/mL. Simultaneously, every 30 days during storage, the free fatty acidity (FFA), peroxide value (PV), and UV absorbance values (K232 and K270) of the olive oil were determined. The results show that *S. boulardii*, as a probiotic yeast, was able to maintain its viability in olive oil over a three-month storage period; survival was largely preserved in nFi at the end of three months' storage, whereas it decreased by approximately 2 log in Fi. The pre-revitalization process did not increase survival in the long term. The method provides an applicable scheme for reliable yeast enumeration in a hydrophobic oil matrix. It was determined that the FFA, PV, and K270 values measured in inoculated olive oils during storage remained within legal limits. The findings indicate that *S. boulardii* can maintain its viability in olive oil and that probiotic culture inoculation does not have a significant adverse effect on the fundamental physico-chemical quality of the oil. In this context, it is considered that the development of probiotic microorganisms in olive oil could expand the range of probiotic products and serve as an alternative food for probiotic consumers.

Abstract

Potassium permanganate and sodium hypochlorite, commonly used in the bleaching of denim fabrics, provide high decolorization efficiency but present certain limitations regarding environmental impact and textile performance. This study comparatively examines the behavior and sustainability aspects of these two oxidizing agents under different application systems. Twenty-five bleaching trials were conducted on 100% cotton indigo denim fabrics, in which potassium permanganate and sodium hypochlorite were applied at various concentrations and durations using both a conventional drum method and a new-generation application technique designed to minimize chemical consumption. After each treatment, key physical properties such as tearing strength and dry/wet rubbing fastness were evaluated, and parameters including chemical usage, water consumption, and energy requirements were analyzed. The results indicate that alternative application systems can achieve up to 80% savings in chemical and water consumption for both oxidants, while also reducing fiber damage and yielding higher rubbing fastness values. Overall, the findings demonstrate that the sustainable use of bleaching chemicals in denim production is influenced not only by chemical formulation but also by the application technology. The integration of potassium permanganate and sodium hypochlorite with alternative application methods that reduce environmental impact and minimize performance loss presents a significant opportunity for sustainable textile chemistry.

Abstract

Titanium dioxide (TiO_2) quantum dots (QDs) exhibit unique optical and electronic properties governed by their particle size and distribution. However, the accurate microscopic characterization of these nanostructures is often hindered by their strong tendency to agglomerate due to high surface energy. This study investigates the synthesis of anatase TiO_2 QDs via a sol-gel reflux condensation method and systematically evaluates the effects of post-synthesis thermal treatment and solvent dispersion techniques on microscopic visualization. The synthesized QDs were characterized using XRD, EDS, SEM, and AFM. X-ray diffraction confirmed the formation of a pure Anatase phase. Energy Dispersive X-Ray Spectroscopy (EDS) revealed that calcination at 450°C is essential for achieving stoichiometric TiO_2 (Ti:O ratio ~1:2) by removing organic residues present in non-calcined samples. Various dispersion protocols involving mechanical grinding and ultrasonication in water, hexane, and ethanol were compared for microscopic sample preparation. The results indicated that nonpolar solvents, such as hexane, introduce surface artifacts, whereas water causes reagglomeration due to high surface tension. The optimal preparation method was identified as calcination followed by ultrasonic dispersion in ethanol. This protocol enabled the visualization of individual crystallites (<10 nm) within small clusters (25-100 nm) using SEM and AFM, providing a reliable methodology for the structural analysis of highly active nanomaterials.

Abstract

This study aimed to determine the microbial composition, antioxidant activity, and volatile aroma compound profiles of boza samples obtained from six traditional producers in Türkiye. The lactic acid bacteria (LAB) counts of the samples ranged between 5.45–9.06 log CFU/mL, while yeast and total aerobic mesophilic bacteria (TAMB) levels showed significant variation depending on fermentation conditions and raw material characteristics. Samples with higher LAB levels exhibited markedly greater antioxidant activity, indicating the strong contribution of LAB metabolism to radical-scavenging capacity. Volatile aroma analysis performed by HS-SPME/GC-MS revealed considerable differences in aroma composition among samples, with key compounds including 3-hexenoic acid, 2-undecenal, muconic acid, acetaldehyde, benzyl alcohol, and phenol. Some samples contained richer and more desirable aroma profiles, whereas others showed limited volatile diversity, likely associated with differences in microbial communities such as the presence of Bacillus spp. Overall, the results demonstrate that boza possesses a diverse microbiome and complex aroma matrix shaped by LAB–yeast interactions and cereal-derived metabolites. These findings highlight the importance of microbial composition and standardized fermentation practices for improving product quality, sensory attributes, and functional potential in traditional boza production.

Abstract

Lung cancer persists as one of the major causes of cancer-associated mortality worldwide. The primary limitations of current therapeutic approaches, such as chemoresistance, systemic toxicity, and immunological adverse effects, have increased the demand for safer and more innovative cancer treatment strategies. Due to their various bioactive metabolites that can regulate tumorgenic pathways, medicinal plants are attracting increasing scientific interest. Among these plants, species of the genus Artemisia have emerged as promising candidates. Specifically, *Artemisia absinthium* has been reported to exhibit antioxidant, anti-inflammatory, and pro-apoptotic activities through key molecular regulators such as iNOS, COX-2, NF-κB, and MEK/ERK. In this study, the cytotoxic effects of *A. absinthium* extract were evaluated in vitro using the human lung adenocarcinoma cell line A549 and human pancreatic ductal adenocarcinoma cell line PANC-1. In order to determine the dose-dependent antiproliferative effects, cells were treated with increasing concentrations of the extract and evaluated using the MTT cytotoxicity assay. According to our results, IC50 value was determined as 4000 µg/mL on A549 and 2000 µg/mL on PANC-1. Our findings indicate that *A. absinthium* induces a dose-dependent growth inhibition in both A549 and PANC-1 cells. These result support the potential of *A. absinthium* as a complementary phytotherapeutic promising therapeutic opinion for lung cancer treatment, although further advanced mechanistic and in vivo studies are required for validation.

Abstract

The present study reports the green synthesis of a TiO_2–Fe_3O_4 nanocomposite using Aloe vera extract as a natural reducing and stabilizing agent, aiming to remove multiple heavy metal ions from aqueous environments. The biomediated sol–gel synthesis successfully produced a nanocomposite with a crystallite size of approximately 14 nm, as determined by X-ray diffraction (XRD). Scanning Electron Microscopy (SEM) analysis revealed a quasi-spherical morphology with aggregated particles, attributing the agglomeration to the presence of biomolecules on the surface. X-ray fluorescence (XRF) analysis confirmed the elemental composition with 35.29 wt% Ti and 9.06 wt% Fe, consistent with the target Fe/Ti molar ratio (0.25). The adsorption performance of the synthesized material was evaluated for As(III), Cd(II), and Hg(II) ions using the Taguchi L_{16} orthogonal array design to optimize key parameters, including pH (3–6), adsorbent dosage (0.05–0.3%), initial concentration (25–100 mg/L), and contact time (30–120 min). Results indicated that pH was the most significant factor influencing adsorption efficiency, with optimal performance at pH 6, 0.05% adsorbent dosage, and 60 min contact time. The composite demonstrated maximum adsorption capacities of 13.3 mg/g for As(III), 160.9 mg/g for Cd(II), and 38.5 mg/g for Hg(II), following the selectivity order Cd(II) > Hg(II) > As(III). The high adsorption capacity was attributed to the synergistic interaction between TiO_2 and Fe_3O_4 phases and the oxygenated functional groups from Aloe vera biomolecules. The magnetic nature of the nanocomposite facilitated rapid and easy recovery after adsorption. This study demonstrates a sustainable and highly efficient approach for multi-metal removal from wastewater by integrating green synthesis and Taguchi-based process optimization, demonstrating scalability and environmental compatibility.

Abstract

Chronic spontaneous urticaria (CSU) is a heterogeneous condition characterized by recurrent wheals and/or angioedema. Objective assessment of disease severity is essential for guiding therapy, yet current tools rely primarily on patient-reported outcomes, which are subjective and variable. Artificial intelligence (AI) offers novel ways to integrate laboratory data into quantitative severity scoring. The aim was to develop a simple, robust, and quantitative severity index (SI) for CSU using routinely available laboratory parameters: eosinophils (EO), basophils (BA), and vitamin D (VIT D). The developed formula normalizes these values, applies nonlinear scaling to emphasize critical deficiencies, and sums them to give a robust, clinically interpretable severity score from 0 to 10. It works independently of CSU endotype type and can be tracked over time. This laboratory-based SI may offer a practical, quantitative, and reproducible method to assess CSU severity, but will need to be validated in clinical practice. Integration with artificial intelligence (AI) approaches could enhance SI predictive value, allowing automated calculation, pattern recognition, and longitudinal monitoring to support personalized management and optimize therapy.

Keywords: SI (Severity Index), CSU, artificial intelligence, basopenia, eosinopenia, Vitamin D

INTRODUCTION

CSU is a chronic inflammatory disorder with variable severity and clinical presentation. Existing severity scores, rely on patient-reported outcomes and may be influenced by subjective perception. Laboratory biomarkers reflecting immune and nutritional status, EO, BA, and VIT D are biologically relevant, but have not been systematically combined into a quantitative severity score.

Blood basophils are reduced in chronic urticaria(Puxeddu et al. 2019) and respond less well to immunologic stimuli. Active recruitment of basophils from peripheral blood into lesional skin may be important in wheal pathogenesis. (Grattan, 2001)Eosinopenia in patients with CSU is associated with type IIb autoimmunity, high disease activity, and poor response to treatment. Eosinophils should be explored as biomarkers and investigated for their contribution to the pathogenesis of CSU.(Kolkhir et al., 2020)vitamin D level is more likely to be critically low in patients with chronic urticaria, and an inverse relationship with disease severity and disease duration has been observed. (Woo et al., 2015) These findings may open up the possibility of the clinical use of vitamin D as a contributing factor in the pathogenesis of chronic urticaria and a predictive marker for disease activity in chronic urticaria.(Woo et al., 2015) There is no validated quantitative tool to assess the CSU severity.

MATERIALS AND METHODS

We aimed to present a simple, AI-generated severity index (SI) for CSU using routinely available laboratory parameters: eosinophil count (EO)cells/µL, basophil count (BA) cells/µL and vitamin D level in ng/mL (Vit D).

We implemented AI-assisted reasoning, and available current scientific data, evidencing role of eosinopenia and basopenia in CSU disease activity and decreased Vit D level as a biomarker of disease severity and disease duration to develop a Severity Index (SI).

EO cut off was set 200/µL and BA cut off 10/ µL to define probable clinically relevant eosinopenia and basopenia in CSU physiopathology. Cut off for Vit D level was set 30 ng/mL.

After considering all factors the below formula was developed. The SI is additive, endotype-independent, and robust against extreme lab values.

$$SI = (EOnorm)^{1.5} + (BAnorm)^{1.5} + \frac{30}{\min(\max(VitD,\ 5),\ 50)}$$

Where:

EO_norm = (200 – EO)/200, capped ≥0

BA_norm = (10 – BA)/10, capped ≥0

Vit D factor = 30 / Vit D, capped between 5–50 ng/mL

EO and BA are normalized and mildly nonlinearly weighted to emphasize clinically significant low counts, while Vit D inversely modulates severity.

The formula was designed by AI assisted step by step reasoning to meet these requirements:

EO and BA normalization: (200 − EO)/200 and (10 − BA)/10, capped ≥0

Nonlinear weighting: exponent 1.5 to emphasize low counts

Vitamin D inversion: 30 / Vit D, capped between 5–50 ng/mL to avoid extremeinfluence

RESULTS and DISCUSSION

This AI-generated formula severity index, offers a quantitative, objective approach to CSU severity assessment. The additive design and nonlinear weighting ensure low EO/BA counts meaningfully influence severity without exaggeration, while Vitamin D inversely modulates SI.

The index is scaled to 0–10 for clinical interpretation:

0–2: Mild

2–5: Moderate

5–7.5: Severe

7.5–10: Very severe

Using 1.5 exponent makes the SI sensitive enough to capture biologically meaningful EO/BA depletion, but not so sensitive that lab variability causes huge swings in the score.

Keeps the scale clinically interpretable (0–10) without needing arbitrary caps.

Results (Example Calculations)

PATIENT	EO	BA	VIT D	SI SCORE	SEVERITY
A	120	5	5.88	5.71	Severe
B	180	13	23	1.33	Mild
C	450	25	26	1.15	Mild

Role of AI:

AI identified optimal normalization, nonlinear weighting, and Vitamin D capping.

AI-assisted pattern recognition can automate SI calculation and integrate it with electronic health records.

This SI tool is cheap, as request only hemogram and Vit D in stead of more inflamatory markers. Machine learning models could combine SI with other laboratory and clinical features to refine predictions of disease course and therapeutic response.

The development of a standardized severity index for CSU is essential for improving clinical decision-making, optimizing treatment strategies, and facilitating consistent assessment across diverse patient populations. Integrating artificial intelligence into the creation of such an index offers several meaningful advantages. AI-driven models can analyze large, heterogeneous datasets to identify subtle patterns in symptom presentation, treatment response, and disease progression that may be overlooked by traditional scoring systems. This allows for a more precise, personalized assessment of disease severity.

Moreover, an AI-generated severity index can adapt over time as new clinical data become available, ensuring that the scoring model remains current and evidence-based. It can also improve objectivity, reducing variability between clinicians and enhancing the reliability of severity measurements in both clinical practice and research settings. Importantly, AI tools can integrate patient-reported outcomes, biomarker profiles, and real-time monitoring data to produce a more holistic view of disease burden.

CONCLUSION

This AI-assisted a simple Severity Index for chronic spontaneous urticaria using eosinophils, basophils, and Vitamin D. Low EO/BA counts and low Vitamin D increase severity. The formula normalizes these values, applies nonlinear scaling to emphasize critical deficiencies, and sums them to give a robust, clinically interpretable severity score from 0 to 10.

Leveraging AI to develop a CSU severity index has the potential to enhance diagnostic accuracy, support individualized treatment pathways, streamline clinical workflows, and ultimately improve patient outcomes. As these technologies continue to evolve, they hold significant promise in advancing the precision and effectiveness of CSU management.

Abstract

Atherosclerotic cardiovascular diseases, representing the major component of cardiovascular diseases, constitute a significant global health concern, as their morbidity and mortality rates are expected to increase in the coming years. Lipid-lowering drugs (LLDs) are beneficial for both the prevention and treatment of atherosclerotic diseases; consequently, several LLDs, including statins and fibrates, have been incorporated into the Reimbursed Drug List in Albania. This study aimed to identify and evaluate the utilization and reimbursement trends of antihyperlipidemic drugs in the Albanian pharmaceutical market within the context of clinical recommendations for dyslipidemia management. A retrospective, descriptive study was used to analyze LLD utilization and reimbursement costs in Albania from 2014 to 2024, using the Anatomical Therapeutic Chemical/Defined Daily Dose (ATC/DDD) methodology recommended by the World Health Organization. Data on LLDs were obtained from the Mandatory Health Care Insurance Fund database, while population data were sourced from the Institute of Statistics' database. Drug utilization was quantified as DDDs per 1,000 inhabitants per day, providing a standardized measure of consumption. Overall, both the utilization and reimbursement of LLDs increased over the study period. Statins were the most commonly used LLDs and accounted for the greatest proportion of total reimbursement for antihyperlipidemic drugs. Atorvastatin and fenofibrate were the most frequently consumed agents, jointly representing 92% of LLD utilization in 2024. Furthermore, their costs were high, accounting for 91% of total LLDs reimbursement in 2024. Atorvastatin appeared to be cost-effective, based on its average price per DDD. In conclusion, the utilization and reimbursement trends of LLDs in Albania align with international lipid management guideline recommendations. Moreover, other effective LLDs already authorized for sale in the country may be considered for future inclusion in the Reimbursed Drug List.

Keywords: lipid-lowering drugs, statins, fibrates, utilization, reimbursement trends.

INTRODUCTION

Cardiovascular diseases (CVDs) are the primary cause of death worldwide and a significant factor in disability. In 2022, CVDs accounted for approximately 32% of global deaths, of which 85% were attributable to ischemic heart disease (IHD) and stroke (WHO, CVDs, 2025). Moreover, CVD-related morbidity and mortality are expected to rise in the coming decades. Between 2025 and 2050, cardiovascular prevalence is projected to increase by 90%, and mortality by 73.4%, with atherosclerotic cardiovascular diseases (ASCVDs), such as IHD and stroke, anticipated to be the main causes of the growing burden of CVD (Chong et al., 2025).

Nowadays, it is well established that elevated levels of low-density lipoprotein cholesterol (LDL-C) are not merely a risk factor but a major causal determinant in the development of ASCVD. A 2015 study reported that the prevalence of dyslipidemia in Albania was 58.6%, indicating that approximately 1.4 million Albanians had at least one major risk factor for dyslipidemia. The study found that total hypercholesterolemia (TC ≥ 200 mg/dL) affected 44.3% of the population. The prevalence of LDL-C ≥ 130 mg/dL, high-density lipoprotein cholesterol (HDL-C) ≤ 40 mg/dL, and triglycerides (TG) ≥ 150 mg/dL was 34%, 17.2%, and 22.6%, respectively (Shurdha et al., 2015). The risk of both fatal and non-fatal myocardial infarctions and ischemic strokes, as well as peripheral arterial ischemic events, has been reduced by lowering LDL-C levels, as demonstrated in numerous randomized trials. Therefore, for preventing atherosclerotic cardiovascular events, the focus should be on lowering plasma LDL-C levels (Mach et al., 2025).

Given the substantial and persistent burden of dyslipidemia in Albania, as described above, the management of this condition is of particular importance. For this reason, several lipid-lowering drugs (LLDs) have been reimbursed in the country during the period 2014-2024. The Reimbursed Drug List has incorporated statin monotherapies (lovastatin, pravastatin, simvastatin, atorvastatin, and fluvastatin) as well as a combination of a statin with a calcium channel blocker, in addition to the fibrates (ciprofibrate and fenofibrate) (Drug List).

The study aimed to determine and evaluate the eleven-year trends in LLD utilization and reimbursement costs in Albania, identifying the most widely used and most costly drugs, within the context of international and national guideline recommendations for the management of dyslipidemia.

MATERIALS AND METHODS

The annual data for all drugs reimbursed in Albania during the years 2014–2024 were obtained from the Mandatory Health Care Insurance Fund (the Fund) database. The Fund is the sole legal, public, and autonomous entity responsible for managing compulsory health care insurance in the Republic of Albania. The standard package of health insurance services includes a Reimbursed Drug List, which is updated regularly, typically once per year, and approved by a decision of the Council of Ministers (Law No. 10383, dated 24.2.2011). Drugs on this list are classified according to their international nonproprietary name (INN), following the Anatomical Therapeutic Chemical (ATC) classification system. Prescribing reimbursed medications by generic name or INN is mandatory, except for veterans and war invalids. Data on LLDs within ATC code C10 were extracted from the full dataset of reimbursed drugs.

A retrospective, descriptive study was conducted using the ATC classification system and the Defined Daily Dose (DDD) as the measurement unit. The DDD represents the assumed average maintenance dose per day for a drug used for its main indication in adults. The ATC/DDD methodology, regarded as the World Health Organization (WHO) gold standard for drug utilization analysis, standardizes the assessment of drug consumption regardless of dose variations, enables comparisons, and facilitates the evaluation of utilization trends over time. Its main purpose is to provide a framework for presenting drug utilization statistics with the aim of improving rational drug use (WHO, Guidelines, 2025).

The DDD values were obtained from the electronic version of the ATC/DDD Index 2025 on the WHO website. Population data used in the study were sourced from the Institute of Statistics (INSTAT) database. Annual drug utilization was expressed as DDDs per 1,000 inhabitants per day (DIDs). Reimbursement values were analyzed as total drug expenditures over the study period, and the average price per DDD was calculated. Ethical review board approval was not needed, as the study relied exclusively on anonymous, aggregated data with no information at the patient level.

RESULTS

Statins and fibrates were reimbursed as LLDs in Albania from 2014 to 2024. Overall utilization of LLDs (ATC code C10) increased during the study period, rising from 6.7 DIDs in 2014 to 22.6 DIDs in 2024. A consistent annual growth pattern was observed in the use of both statins (C10AA) and fibrates (C10AB), whereas the statin and calcium channel blocker combination (C10BX) exhibited negligible consumption (Table 1). Statins accounted for the largest proportion of LLD utilization, representing more than 80% of total use.

Table 1. LLD utilization, expressed in DIDs, from 2014 to 2024

ATC codes	2014	2015	2016	2017	2018	2019	2020	2021	2022	2023	2024
C10	6.7	7.8	8.6	10	11.7	12.8	13.7	14.7	16.2	17.4	22.6
C10AA	5.92	6.9	7.5	8.63	10	10.8	11.5	12.3	13.5	14.7	19.2
C10AB	0.77	0.92	1.1	1.38	1.67	1.96	2.2	2.35	2.7	2.7	3.4
C10BX	0.002	0.004	0.007	0.008	0.015	0.03	0.034	0.03	0.03	0.016	0.01

Atorvastatin was the most widely used statin, accounting for the largest proportion of reimbursed statin consumption and reaching 91% of total statin use in 2023 and 2024 (Figure 1).

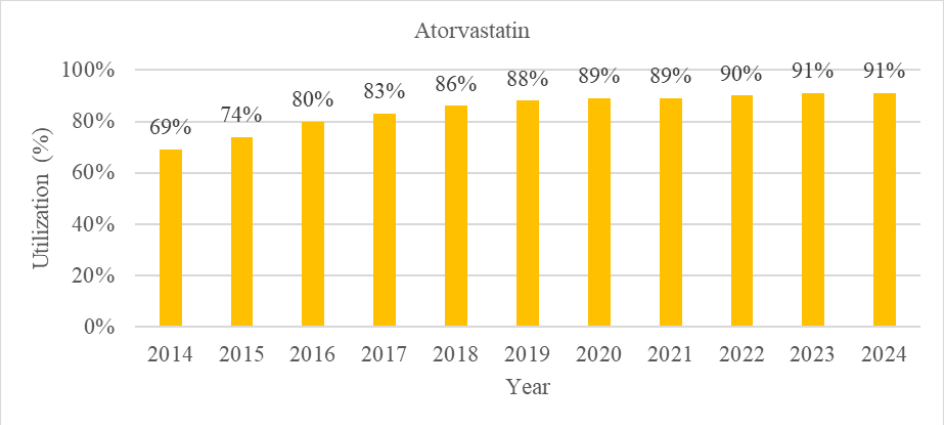

Figure 1. Atorvastatin use as percentage of statin utilization

Simvastatin was the second most frequently used statin, with relatively stable utilization across all years. Fluvastatin, pravastatin, and lovastatin exhibited negligible levels of consumption, and lovastatin has not been used since 2020 (Table 2).

Table 2. Statin utilization, expressed in DIDs, from 2014 to 2024

Statins	2014	2015	2016	2017	2018	2019	2020	2021	2022	2023	2024
C10AA	5.92	6.9	7.5	8.63	10	10.8	11.5	12.3	13.5	14.7	19.2
Simvastatin	1.1	1.12	1.1	1.07	1.1	1.1	1.1	1.1	1.1	1.1	1.3
Lovastatin	0.001	0.002	0.0002	0.0001	0.0003	0.0002	-	-	-	-	-
Pravastatin	0.01	0.01	0.0027	0.0016	0.0004	0.0002	0.0002	0.0005	0.01	0.03	0.05
Fluvastatin	0.7	0.63	0.4	0.38	0.28	0.2	0.2	0.2	0.2	0.2	0.3
Atorvastatin	4.11	5.13	6	7.18	8.61	9.46	10.2	11	12.2	13.4	17.5

Meanwhile, fenofibrate was the most commonly used fibrate, except in 2016 and 2017 when ciprofibrate consumption was higher. Fenofibrate utilization increased steadily throughout the study period, reaching its peak in 2024 (Table 3).

Table 3. Fibrate utilization, expressed in DIDs, from 2014 to 2024

Fibrates	2014	2015	2016	2017	2018	2019	2020	2021	2022	2023	2024
C10AB	0.77	0.92	1.1	1.38	1.67	1.96	2.2	2.35	2.7	2.7	3.4
Fenofibrate	0.55	0.5	0.5	0.65	1.13	1.21	1.4	1.5	1.8	2.4	3.3
Ciprofibrate	0.22	0.42	0.6	0.73	0.54	0.75	0.8	0.85	0.9	0.3	0.1

Fenofibrate consumption in 2024 was six times higher than in 2014 and accounted for 97% of total fibrate utilization in that year (Figure 2).

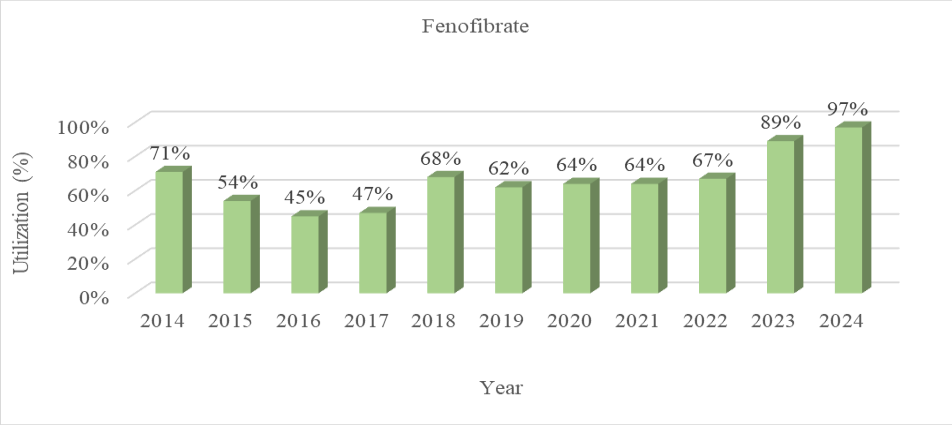

Figure 2. Fenofibrate use as percentage of fibrate utilization

Total reimbursement for LLDs increased over the study period. Although statins accounted for the majority of LLD reimbursement costs, their financial impact gradually declined from 79% in 2014 to 63.7% in 2024. In contrast, fibrate reimbursement expenditures in 2024 were 2.7 times higher than in 2014, whereas the increase for statins over the same period was only 27%. Consequently, fibrate reimbursement costs rose more rapidly than those of statins throughout the study period (Figure 3).

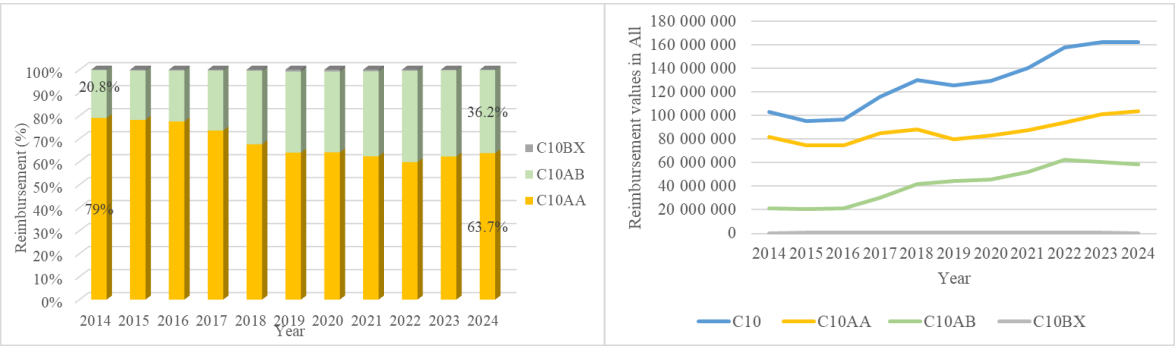

Figure 3. Reimbursement expenditure trends of LLDs from 2014 to 2024

Atorvastatin and fenofibrate expenditures accounted for the largest share of reimbursement costs within the statin and fibrate groups, respectively. The reimbursement gap between fenofibrate and ciprofibrate became more pronounced from 2018 to 2024, consistently favoring fenofibrate. Fenofibrate reimbursement increased steadily throughout the study period, reaching its highest value in 2024, when 99% of total fibrate reimbursement was attributed to fenofibrate alone (Figure 4).

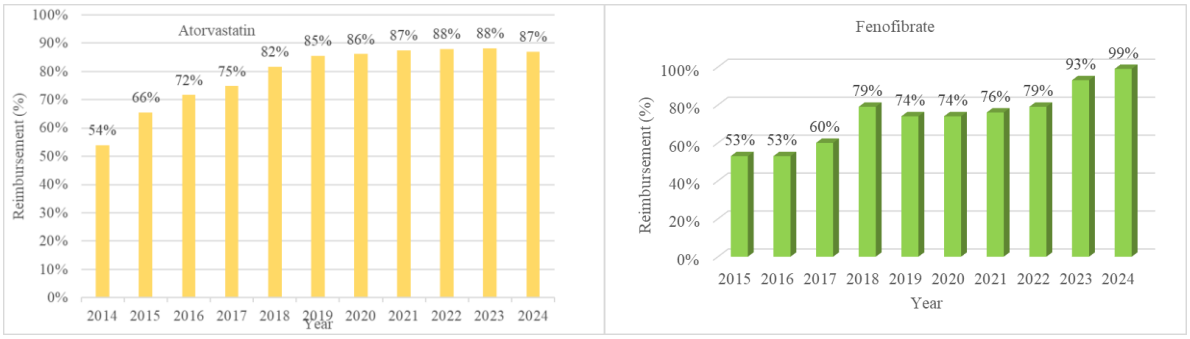

Figure 4. Atorvastatin and Fenofibrate expenditures as percentage of statin and fibrate reimbursement

Atorvastatin and simvastatin had the lowest average prices per DDD, indicating lower expenditures (Figure 5).

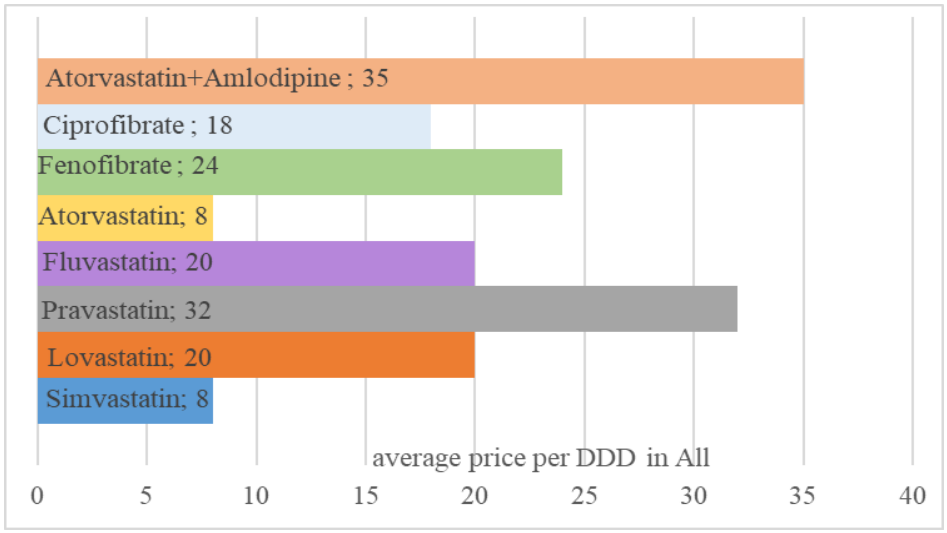

Figure 5. Average price per DDD

In 2024, 92% of LLD utilization and 91% of LLD reimbursement expenditures were attributable to the use and reimbursement of only two drugs, namely atorvastatin and fenofibrate (Figure 6).

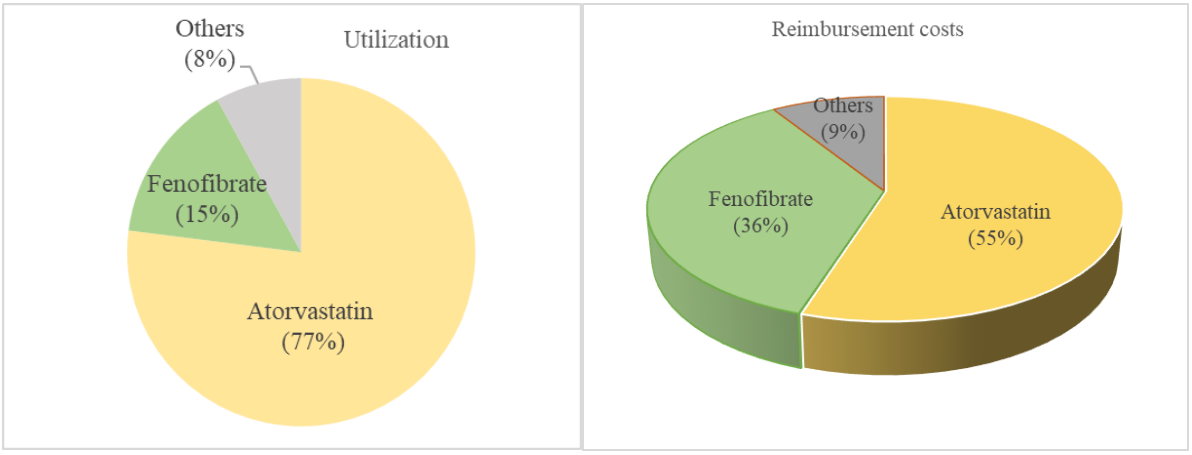

Figure 6. Atorvastatin and fenofibrate versus LLDs in 2024

DISCUSSION

The study demonstrated that the utilization of reimbursed LLDs increased steadily from 2014 to 2024, reaching its highest level in 2024, when consumption was more than threefold higher than in 2014. Statins were the most frequently used drugs, accounting for more than 80% of annual LLD utilization, followed by fibrates. These findings align with the global upward trend in LLD use (Joseph E. Blais et al., 2021), and reflect international and national clinical guideline recommendations that position statins as first-line therapy for the management of dyslipidemia (Mach F et al., 2019; Shehi et al., 2022).

Statins, through their LDL-C-lowering effects, reduce the risk of developing atherosclerotic diseases. Clinical guidelines state that patients at very high-risk and those at high-risk for ASCVD should attain LDL-C targets of <55 mg/dL and <70 mg/dL, respectively, along with at least a 50% reduction from baseline in both categories. The magnitude of LDL-C reduction differs among individual statins and is dose-dependent. High-intensity statin therapy is required to achieve a ≥50% LDL-C reduction, whereas moderate-intensity statin therapy typically results in a 30–50% decrease (Mach F et al., 2019; Shehi et al., 2022). The study found that atorvastatin was the most widely utilized statin, consistent with guideline recommendations that support the use of potent statins for primary and secondary prevention of ASCVD. Rosuvastatin and pitavastatin, two other potent statins, are legally authorized for commercial use in Albania (Drug Register), but neither is currently included in the Reimbursed Drug List.

For patients unable to tolerate the recommended statin intensity due to adverse effects, or for those who fail to achieve treatment goals, adding a non-statin lipid-modifying agent to the maximally tolerated statin dose is recommended. Current clinical guidelines recommend introducing ezetimibe in such cases (Mach F et al., 2019). The combination of ezetimibe with statin therapy produces additional LDL-C reductions (Mach F et al., 2019; Valvukis M. and Valvukis A., 2018). Although several ezetimibe-containing products, whether alone or in combination with a statin, are authorized for sale in the Albanian pharmaceutical market (Drug Register), ezetimibe is not yet reimbursed.

The study also showed that fenofibrate was the most commonly consumed fibrate, contributing substantially to reimbursement expenditures within this drug group. Fibrates are primarily used to reduce triglyceride (TG) levels, with decreases of up to 50%. Their cardiovascular benefits, however, require further confirmation. According to national and international lipid guidelines, fenofibrate or bezafibrate may be considered in combination with statins for high-risk patients who have achieved their LDL-C goal but continue to present with hypertriglyceridaemia [TG >2.3 mmol/L (200 mg/dL)]. When combining statins with fibrates, fenofibrate is preferred due to its minimal or absent skeletal muscle adverse effects (Mach F et al., 2019).

Reimbursement costs for LLDs increased by 57% over the 11-year study period. Although statin expenditures followed this upward trajectory, their overall increase was more modest at approximately 27%. The rise in reimbursement costs was more pronounced for fibrates than for statins, largely attributable to the higher prices of fibrate pharmaceutical products.

It can be anticipated that the actual use and costs of all LLDs marketed in Albania from 2014 to 2024 are considerably higher than the estimates provided in this study. This is because, beyond reimbursed drugs, several other LLDs authorized for marketing in the country are also purchased for effective patient treatment.

CONCLUSION

Over the 11 years from 2014 to 2024, both the utilization and the reimbursement costs of LLDs increased in Albania. Statins were the most widely used drugs and accounted for the highest proportion of reimbursement expenditures, followed by fibrates, which represented the second-largest contribution in terms of both utilization and financial impact. Atorvastatin, the most frequently used statin, appeared cost-effective when considering its average price per DDD. These findings align with international guideline recommendations for dyslipidemia management. In addition, the future inclusion of other effective LLDs within the reimbursement system may be considered with the aim of further enhancing the quality of health care provided to insured patients in Albania.

ORAL PRESENTATION

Identification and management of mold-induced allergies in indoor environments

Brikena Muja (Parllaku), Merita Xhetani, Etleva Hamzaraj, Mirela Lika

University of Tirana, Faculty of Natural Sciences, Department of Biology, Blvd "Zog I", 1001, Tirana, Albania

Abstract

Exposure to indoor air fungi has been increasingly recognized as a significant factor contributing to allergic responses, particularly among students who spend extended periods in educational environments. This study investigates the presence and concentration of airborne fungal spores in indoor settings, such as classrooms and dormitories, and their potential association with allergic symptoms in students. Air samples were collected from multiple indoor environments in a university setting and analyzed for fungal diversity and spore count using culture-based and molecular methods. Concurrently, a questionnaire-based health survey was conducted to assess the prevalence of allergy-related symptoms among students, including rhinitis, asthma, and skin irritation. The results revealed a predominance of fungal genera such as Aspergillus, Penicillium, and Cladosporium, with seasonal and environmental variations influencing their concentrations. A statistically significant correlation was observed between elevated fungal spore levels and the frequency of reported allergic symptoms. These findings highlight the need for improved indoor air quality monitoring and the implementation of preventive measures in academic institutions to reduce allergen exposure and promote student well-being.

Keywords: indoor environment, mold, allergy, symptoms, public health.

Introduction

Mold-induced allergies represent a significant and increasingly recognized public health concern, particularly within indoor environments where individuals spend most of their time. Mold spores are ubiquitous biological particles that proliferate in areas with excessive moisture, inadequate ventilation, or water damage (Beheshti R., *et al.,* 2024; WHO, 2009). When inhaled or in contact with the skin, these spores can trigger immunological reactions ranging from mild respiratory discomfort to severe allergic manifestations, especially in sensitized individuals. Over recent decades, factors such as urbanization, climate change, and the widespread use of energy-efficient but poorly ventilated buildings have contributed to higher concentrations of indoor mold, making the issue more prevalent and clinically relevant (Łukasz Grewling *et al*, 2025; Preuss CV, *et al*,. 2025; O'Connor A, *et al*., 2025).

Understanding mold-induced allergies requires examining both the biological characteristics of molds and the environmental conditions that promote their growth. Common indoor species, including *Aspergillus*, *Penicillium*, *Cladosporium*, and *Stachybotrys*, release spores and microbial volatile organic compounds (mVOCs) that can exacerbate allergic rhinitis, asthma, chronic sinusitis, and skin irritations. Children, the elderly, and individuals with pre-existing respiratory conditions are particularly vulnerable to these effects. Early identification of mold exposure—through environmental assessment, clinical evaluation, and symptom tracking—is essential for accurate diagnosis, prevention of complications, and implementation of targeted interventions (Beheshti R. *et al.*, 2025; C-E Pogner, *et al*, 2024; Mendell, M. J., *et al*. 2011).

Management strategies for mold-induced allergies must combine medical treatment with environmental control. Pharmacological approaches such as antihistamines, intranasal corticosteroids, and leukotriene modifiers can alleviate symptoms, while immunotherapy may provide long-term benefits for highly sensitized individuals. However, medical treatment alone is insufficient without addressing environmental triggers. Effective remediation requires moisture control, improved ventilation systems, removal of contaminated materials, and adherence to established indoor air quality guidelines. Preventive strategies—particularly in homes, workplaces, schools, and healthcare facilities—play a crucial role in reducing recurrence and protecting at-risk populations. (Bush, R. K., & Portnoy, J. M. 2001; Kew KM, *et al*., 2017; Patti MA, *et al*., 2025).

This article explores the mechanisms, clinical presentation, diagnostic methods, and evidence-based management of mold-induced allergies in indoor environments. By integrating environmental science with clinical practice, it aims to support more effective identification, intervention, and long-term control of this growing public health issue (Łukasz Grewling *et al*, 2025; Preuss CV, *et al*,. 2025).

Materials and Methods

A cross-sectional study was conducted involving 120 university students residing in dormitories and attending classes in selected buildings with varying ventilation and humidity conditions. Participants were aged between 18 and 25 years. Informed consent was obtained from all participants, and the study protocol was approved by the institutional ethics committee.

Indoor Air Sampling

Indoor air samples were collected from classrooms, study rooms, and dormitories using a volumetric air sampler (e.g., Andersen sampler). Sampling was conducted during both humid and dry seasons to assess environmental variation. Petri dishes with Sabouraud Dextrose Agar (SDA) were used to culture airborne fungi. Plates were incubated at 25°C for 5–7 days, and colonies were identified morphologically and microscopically. Common genera such as Aspergillus, Penicillium, and Cladosporium were recorded.

Assessment of Allergic Symptoms

Allergic symptoms among students were assessed using a standardized questionnaire based on the International Study of Asthma and Allergies in Childhood (ISAAC), adapted for young adults. Data collected included respiratory symptoms (e.g., sneezing, nasal congestion), dermatological reactions (e.g., eczema), and history of diagnosed allergies.

Immunological Methods

Blood Sample Collection

Venous blood samples (5 mL) were collected from 60 students reporting allergic symptoms and 30 asymptomatic controls. Samples were centrifuged, and serum was stored at -20°C until analysis.

Total and Specific IgE Measurement

Total IgE levels were measured using an enzyme-linked immunosorbent assay (ELISA) kit (e.g., from Thermo Fisher Scientific).

Specific IgE antibodies against common fungal allergens (Aspergillus fumigatus, Cladosporium herbarum, Penicillium notatum) were detected using ImmunoCAP (Phadia) or an equivalent fluorescent enzyme immunoassay system

Skin Prick Test (SPT)

A subset of students underwent skin prick testing using standardized fungal allergen extracts. The allergens tested included Aspergillus mix, Cladosporium, and Alternaria. Histamine and saline were used as positive and negative controls, respectively. A wheal diameter ≥3 mm compared to the negative control was considered positive.

Statistical Analysis

Data were analyzed using SPSS v26. IgE levels and symptom frequency were compared between exposed and non-exposed groups using t-tests and chi-square tests. Pearson correlation was used to assess the relationship between fungal load and IgE levels. A p-value < 0.05 was considered statistically significant.

Results and discussion

Firstly, we have studied Fungal Concentrations in Indoor Air. Air samples revealed the presence of Aspergillus, Penicillium, and Cladosporium in all locations. Dormitories showed the highest fungal concentrations, particularly for Aspergillus (up to 180 CFU/m³).

Table 1: Mean Fungal Spore Concentrations (CFU/m³) by Location

Location		Aspergillus.	Penicillium	Cladosporium
Classroom	A	120	80	60
Classroom	B	90	70	50
Dormitory	A	150	100	85
Dormitory	B	180	110	95

For total IgE Levels, Students reporting allergic symptoms had significantly higher total serum IgE levels (mean: 303 IU/mL) compared to asymptomatic controls (mean: 75 IU/mL).

Table 2: Total IgE (IU/mL) in Allergic vs Control Groups

Group	Mean	Std.Dev	Min	Max
Allergic	303	17.6	285	320
Control	75	15.3	60	90

We determine the Prevalence of Allergic Symptoms, the data are as follows:

Table 3: Reported Allergy Symptoms Among Students. A bar chart would display these values.

Symptom	% of Students Affected
Sneezing	52%
NasalCongestion	45%
Wheezing	30%
Eczema	25%

The findings demonstrate a clear association between exposure to indoor fungal spores and the presence of allergic symptoms in students. Dormitory environments, with typically poor ventilation and higher humidity, showed the highest concentrations of allergenic fungi. This aligns with previous studies linking Aspergillus and Cladosporium exposure to respiratory and dermal allergic responses.

The significantly elevated IgE levels in symptomatic students further support a Type I hypersensitivity reaction, likely mediated by fungal allergens. Skin prick testing and specific IgE assays would help confirm sensitization patterns in future research.

These results underscore the importance of monitoring indoor air quality in academic settings. Interventions such as improving ventilation, reducing indoor humidity, and regular cleaning could mitigate fungal proliferation and reduce allergen exposure among students.

Environmental studies consistently demonstrated a strong correlation between elevated indoor humidity levels above 60%, water-damaged structures, and increased mold proliferation. Homes lacking adequate ventilation exhibited significantly higher concentrations of airborne mold spores. Clinical studies showed that exposure to indoor mold contributes to increased rates of asthma exacerbations, allergic rhinitis, and chronic sinusitis. Diagnostic methods such as skin prick testing and serum IgE analysis were found to be reliable tools for identifying mold sensitization. Pharmacological treatments including antihistamines, leukotriene receptor antagonists, and intranasal corticosteroids were effective in managing symptoms. Environmental interventions—improving ventilation, reducing humidity, repairing leaks, and removing mold-contaminated materials—were shown to significantly reduce symptom recurrence and improve patient outcomes.

Table 4. Key environmental risk factors for indoor mold growth and recommended control measures.

Risk factor	Typical example	Recommended control measure
High relative humidity (>60%)	Poorly ventilated bathroom or kitchen	Use exhaust fans, dehumidifiers, and keep humidity between 40–60%.
Water intrusion or leaks	Leaking roof, pipe, or window frame	Repair leaks promptly and dry affected materials within 24–48 hours.
Condensation on cold surfaces	Condensation on windows, exterior walls, or pipes	Improve insulation, increase air circulation, and control indoor humidity.
Inadequate ventilation	Sealed windows and blocked vents	Open windows, when possible, maintain HVAC systems, and ensure fresh air exchange.
Porous materials staying damp	Wet carpets, drywall, or cardboard	Remove or replace contaminated materials; avoid long-term storage of paper and textiles in damp areas.

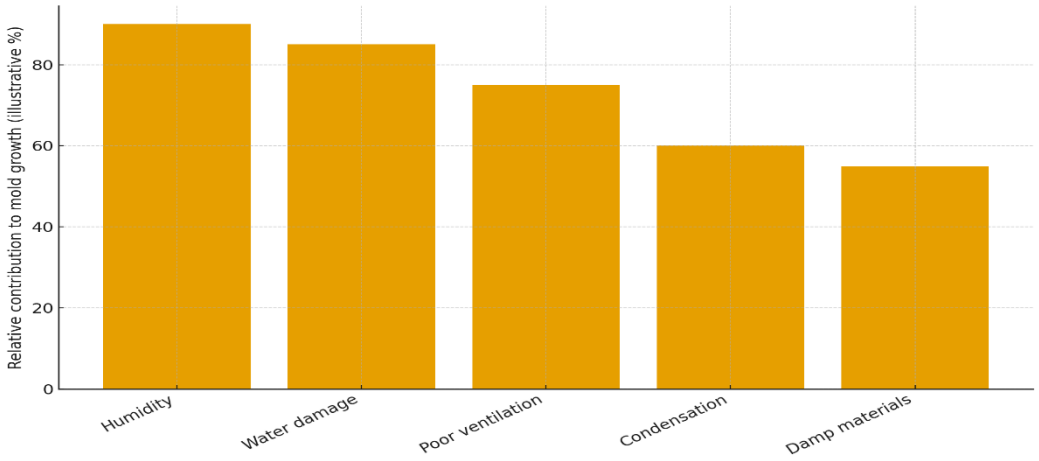

Figure 1. Illustrative relative contribution of key indoor factors to mold growth

This bar chart provides an illustrative comparison of how major indoor environmental factors contribute to mold growth. Actual values will vary by building type and climate, but the figure emphasizes the dominant role of humidity and water damage.

Conclusion

Mold-induced allergies remain a major public health issue in indoor environments. Findings from reviewed studies highlight the interplay between biological susceptibility and environmental conditions. Effective management requires a dual approach: medical treatment to alleviate symptoms and environmental remediation to eliminate mold sources. Improving indoor air quality through moisture reduction, ventilation enhancement, and prompt repair of water damage is essential. Future research should focus on creating standardized indoor mold assessment protocols and developing sustainable prevention strategies to reduce allergic disease burden.

ORAL PRESENTATION

"Challenges and opportunities in preserving natural resources" in Albania

*Silvana Nakuci[1] (Orcid: 0009-0008-6460-0028)

[1]Department of Economy and Rural Development Policies, Faculty of Economy and Agribusiness, Agricultural University of Tirana/ Tirana, Albania

Abstract

This study examines the key challenges associated with the conservation and management of natural resources. Drawing on qualitative methodologies, including semi-structured interviews and field observations, the research identifies the main factors contributing to environmental degradation, such as uncontrolled exploitation, pollution, climate change, and the absence of effective institutional mechanisms. The analysis reveals that local actors play a crucial role in perceiving and addressing these challenges; however, their efforts are often hindered by financial constraints, weak interinstitutional coordination, and limited public awareness. The study highlights the importance of community engagement and the strengthening of sustainable policies to ensure the effective and long-term management of natural resources.

Keywords: challenges, natural resources, sustainable management, local actors, environmental protection.

1.Introduction

This study aims to analyze the challenges associated with the conservation of natural resources by assessing the perceptions and concerns of local stakeholders and highlighting the importance of comprehensive approaches to sustainable resource management. Environmental degradation is emerging as a global threat, adversely affecting public health and quality of life. Population growth and increasing consumption intensify climate change, accelerating the depletion of natural resources and jeopardizing their long-term sustainability (Zhang, 2021).

To utilize natural resources effectively, individuals must possess adequate knowledge of the environment, its importance, and its underlying dynamics. Moreover, environmental action requires structured, functional support across multiple levels, as well as the provision of necessary financial resources to implement sustainable measures (Kozera-Kowalska, 2024). Although the expansion of protected areas is relatively easy to implement, it often overlooks biodiversity, ecosystem services, and social equity. Therefore, assessing the effectiveness of management and governance should be an essential component in achieving natural resource conservation objectives (Hoffmann, 2022). By assessing the extent of environmental indicator deterioration, policymakers can more accurately determine priorities for resource allocation and design more effective strategies for addressing environmental challenges. (Solangi, 2023). In this paper, we present the latest research and developments concerning the challenges and opportunities in natural resource conservation. The study was conducted based primarily on data collected from stakeholders in various regions of Albania, and the research method employed was a Google Forms–based survey.

2. Literature Review

Natural resources constitute the foundation of human existence and development. They not only sustain the biological and ecological processes of life but also drive the economic, social, and technological advancement of human societies. This study examines the challenges and opportunities in natural resource conservation, as well as the impact that natural resources have on the well-being of various communities. Digitalization and technological innovation offer substantial potential for sustainable resource management by reducing environmental impacts, increasing efficiency, and improving socio-economic outcomes. This stems from the transformative role that technology can play in contemporary resource management (Jianing, 2024). Among the most critical natural resources are air, forests, and water. Air not only provides oxygen but also offers protection from cosmic radiation and pollutants, while forests and oceans contribute to carbon dioxide absorption and the mitigation of climate change. Water, essential for consumption, agriculture, and industry, originates directly from the Earth's natural sources, supporting both ecosystem functioning and human activities (Thomas, 2023). Sustainable management of natural resources has gained critical importance as global ecosystems face continuous

pressures from human activities. Fundamental resources such as water, soil, forests, and biodiversity are being degraded at rapid rates due to industrialization, urbanization, and unsustainable agricultural practices (Zhang M. , 2025). In a period of declining natural resource availability, the implementation of more resilient and adaptable supply systems, including various energy conversion technologies such as solar thermal and photovoltaic panels, can lay the foundation for a less resource-intensive urban lifestyle (Zucaro, 2025).

3. Results of the study

Sustainable management of natural resources is increasingly essential today due to population growth, urbanization, and global environmental crises. Their uncontrolled exploitation threatens not only ecological balance but also social well-being and economic stability. This study relied on various stakeholders to assess their impact and readiness for natural resource conservation. Our research was based on the analysis of 85 questionnaires, with the results presented as follows:

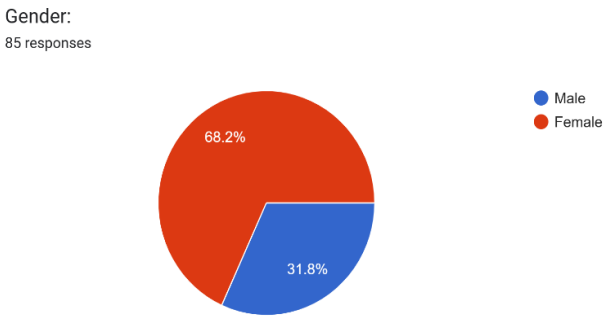

Figure 1. Gender of the respondents

The figure above shows the result of gender of the 85 interviews, 68.2% are female and 31.8% are male.

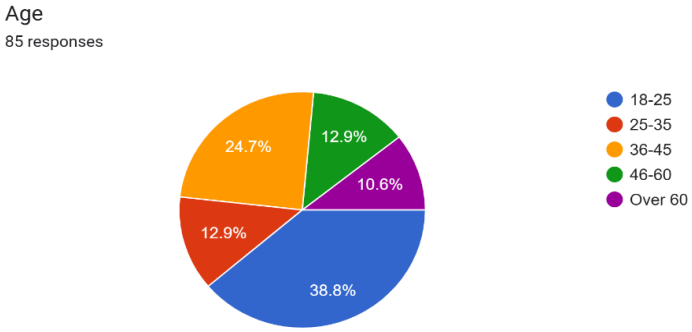

Figure 2. Age of the respondents

The figure above illustrates the age distribution of the respondents: 38.8% are 18–25 years old, 12.9% are 26–35 years old, 24.7% are 36–45 years old, 12.9% are 46–60 years old, and 10.6% are over 60 years old.

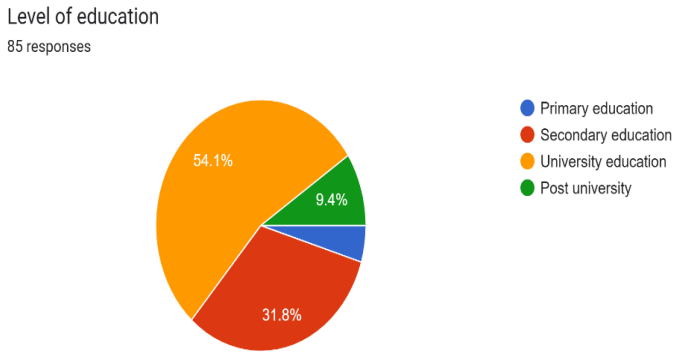

Figure 3. Education level of the respondents

The figure above shows the education levels of the respondents. Out of 100% of the participants, 54.1% have a university education, 31.8% have completed secondary education, 9.4% have postgraduate education, and 4.7% have primary education.

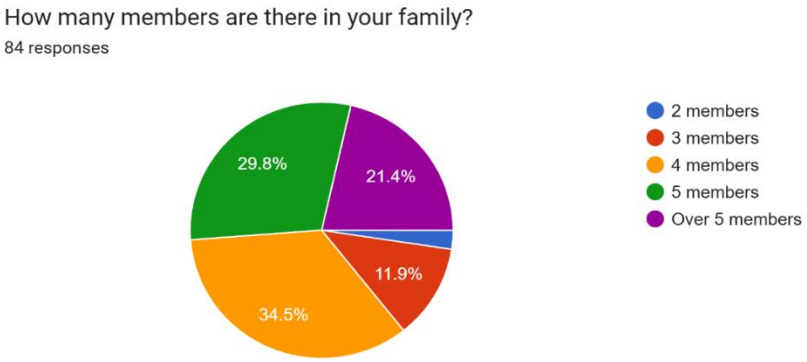

Figure 4. How many members are in your family?

The figure above shows the family size of the respondents. The largest group, 34.5%, lives in families with 4 members, 29.8% live in families with 5 members, 21.4% live in families with more than 5 members, 11.9% live in families with 3 members, and 2.3% live in families with 2 members.

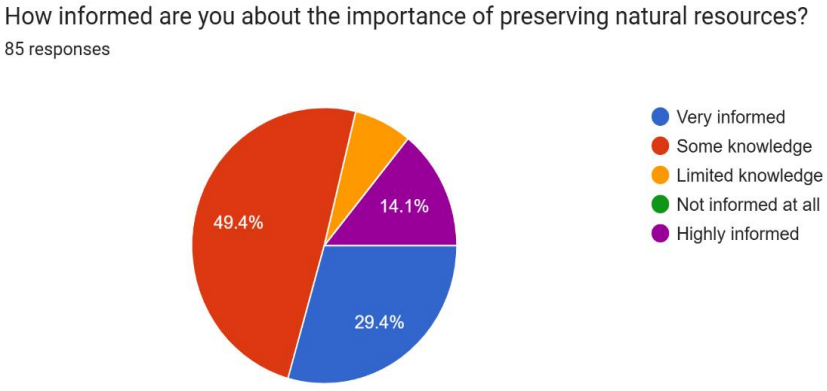

Figure 5. How informed are you about the importance of natural resource conservation?

Respondents were asked about their level of awareness regarding the importance of conserving natural resources. The results indicate that 49.4% of respondents have only some knowledge, 29.4% are informed, 14.1% consider themselves very well informed, and 7.1% report having little knowledge.

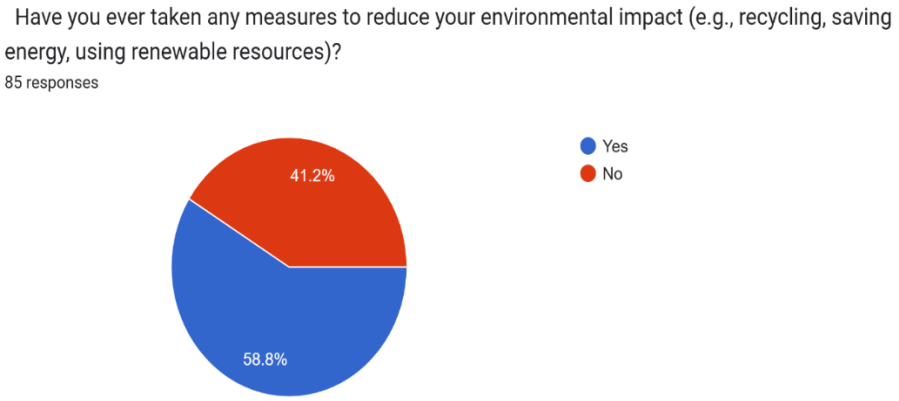

Figure 6. Have you ever taken measures to reduce your environmental impact (e.g., recycling, saving energy, using renewable resources)?

Regarding the measures respondents have taken to reduce their environmental impact, such as recycling, saving energy, or using renewable resources, 58.8% answered "Yes," while 41.2% indicated "No," reporting that they have never taken measures to reduce their environmental impact.

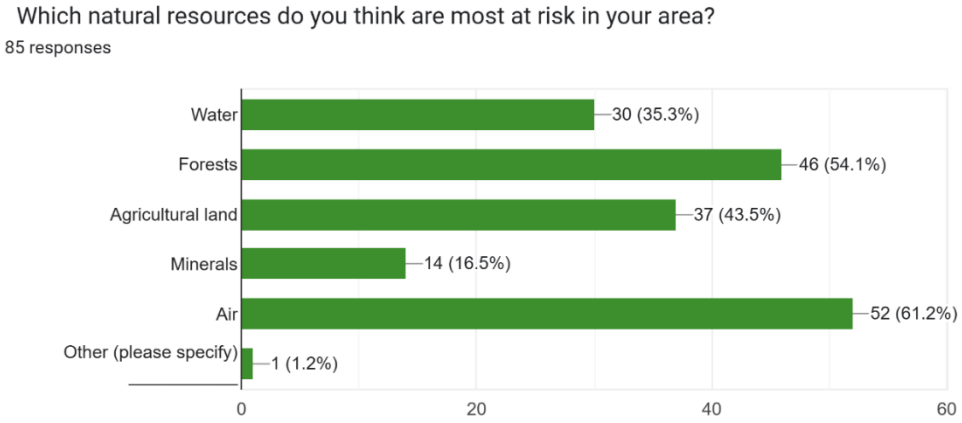

Figure 7. Which natural resources do you consider most at risk in your area?

Respondents were asked about the natural resources they consider most at risk in their areas. According to the study, the natural resources identified as most at risk were: air, forests, agricultural land, water, and minerals.

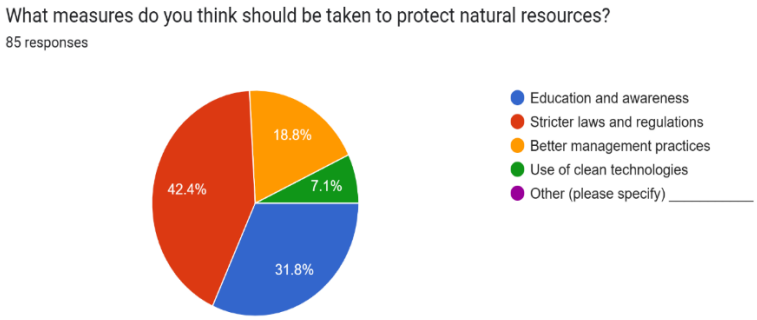

Figure 8. What measures do you think should be taken to protect natural resources?

The figure above illustrates the measures that respondents believe should be taken to protect natural resources. According to the survey results: 31.8% of respondents believe that measures should focus on education and awareness-raising among all stakeholders, 42.4% think that stricter laws and regulations should be implemented, 7.1% suggest using clean technologies, and 18.8% believe that measures should rely on best management practices.

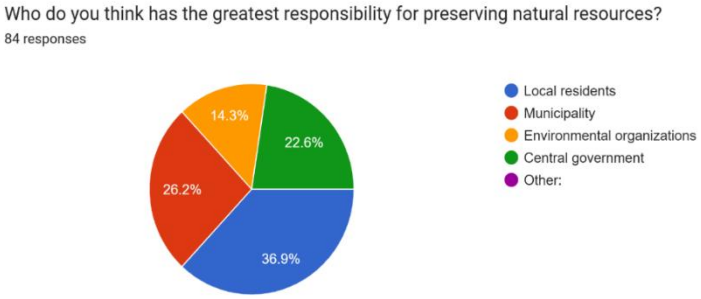

Figure 9. Who do you think holds the greatest responsibility for conserving natural resources?

Regarding the question of who holds the greatest responsibility for conserving natural resources, respondents answered as follows: 36.9% believe the responsibility lies with local residents, 26.2% with municipalities or communities, 14.3% with environmental organizations, and 22.6% with the central governmen.

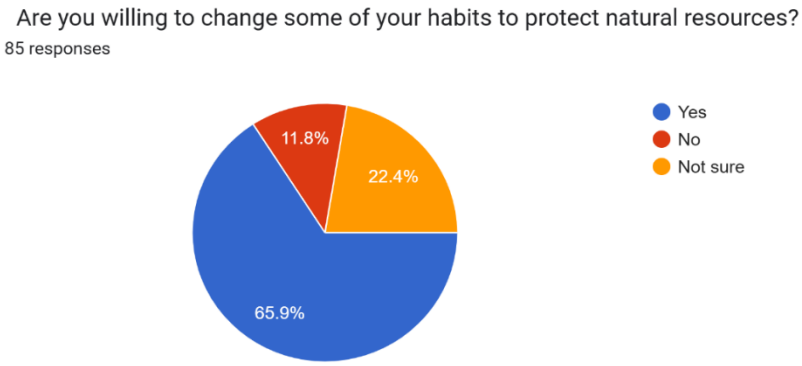

Figure 10. Are you willing to change some of your habits to protect natural resources?

The figure above illustrates respondents' willingness to change certain habits to protect natural resources. The results show that 65.9% are willing to change their habits, 11.8% are not willing, and 22.4% are uncertain about whether they want to modify their habits for natural resource conservation.

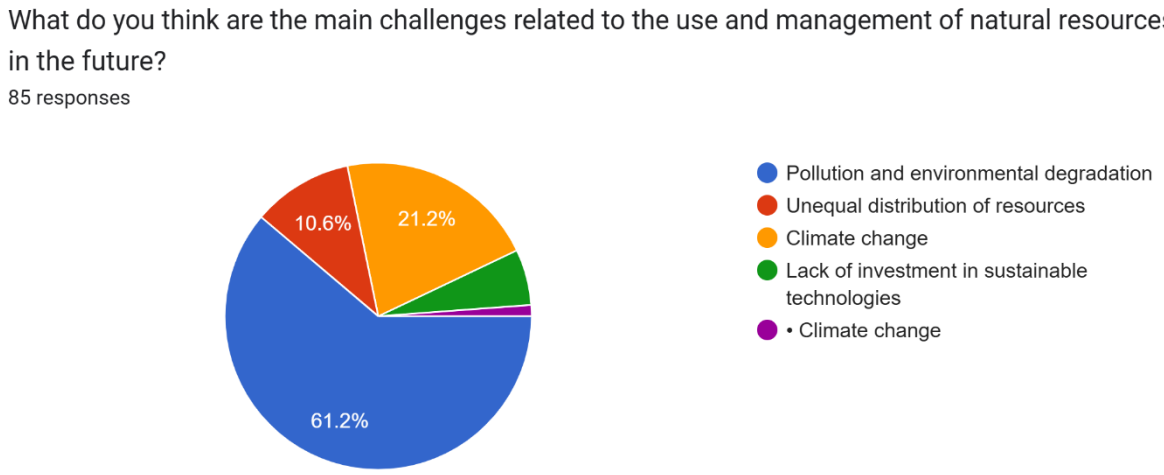

Figure 11. In your opinion, what are the main challenges related to the use and management of natural resources in the future?

Regarding the question of the main challenges related to the use and management of natural resources in the future, the responses from 100% of the participants were as follows: 61.2% believe the main challenge is pollution and environmental degradation, 21.2% consider climate change to be the primary challenge, 10.6% think the main challenge is the unequal distribution of resources, and 7% believe the primary challenge is the lack of investment in sustainable technologies

4.Conclusions

According to the study, out of 85 respondents, 68.2% were female and 31.8% were male. The age distribution of respondents was as follows: 38.8% were 18–25 years old, 12.9% were 26–35 years old, 24.7% were 36–45 years old, 12.9% were 46–60 years old, and 10.6% were over 60 years old.

Regarding education, 54.1% of respondents had a university-level education, 31.8% had completed secondary education, 9.4% had postgraduate education, and 4.7% had primary education.

Most respondents live in families with 4 members (34.5%), 29.8% live in families with 5 members, 21.4% live in families with more than 5 members, 11.9% live in families with 3 members, and 2.3% live in families with 2 members.

Respondents were asked about their level of awareness regarding the importance of conserving natural resources. The results show that 49.4% of respondents have only some knowledge, 29.4% are informed, 14.1% consider themselves very well informed, and 7.1% report having little knowledge. Regarding the measures respondents have taken to reduce their environmental impact (e.g., recycling, saving energy, using renewable resources), 58.8% of respondents answered Yes, while 41.2% stated that they have never taken any measures to reduce their environmental impact, answering No. Respondents were also asked about the natural resources they consider most at risk in their areas. According to the study, the most endangered resource was air, followed by forests, agricultural land, water, and minerals.

Regarding the measures that should be taken to protect natural resources, 31.8% of respondents believe that actions should focus on education and raising awareness among all stakeholders, 42.4% think stricter laws and regulations should be implemented, 7.1% suggest the use of clean technologies, and 18.8% believe measures should rely on best management practices Regarding the question of who holds the greatest responsibility for conserving natural resources, respondents answered as follows: 36.9% believe the responsibility lies with local residents, 26.2% with municipalities or communities, 14.3% with environmental organizations, and 22.6% with the central government. Additionally, concerning respondents' willingness to change certain habits to protect natural resources, 65.9% indicated they are willing to modify their habits, 11.8% stated they are not willing, and 22.4% were uncertain about whether they want to change their habits for the protection of natural resources. Regarding the question of the main challenges related to the use and management of natural resources in the future, the responses from 100% of

the participants were as follows: 61.2% believe the primary challenge is pollution and environmental degradation, 21.2% consider climate change to be the main challenge, 10.6% think the main challenge is the unequal distribution of resources, and 7% identify the lack of investment in sustainable technologies as the primary challenge.
According to the study, the data indicate that awareness of natural resources is partial, while the willingness to implement practical changes exists among a considerable portion of the community. The results also emphasize the importance of combined interventions through education, legislation, management practices, and the use of clean technologies to ensure the conservation and sustainable management of natural resources.

5. Recommendations

Enhancing Environmental Awareness and Education
Considering that a significant portion of respondents have limited knowledge about the importance of natural resources, it is recommended to develop educational programs and awareness campaigns that involve all local stakeholders and the wider community.
Strengthening Legislation and Enforcement of Regulations
Since 42.4% of respondents support stricter laws and regulations, it is necessary to reinforce the legal framework for natural resource protection and ensure its effective implementation by competent authorities.
Promoting Sustainable Practices and the Use of Clean Technologies
To reduce the negative impact of human activities on the environment, it is recommended to promote best management practices, recycling, energy saving, and the use of renewable resources, including the adoption of clean technologies.
Strengthening the Role of Local Actors
Given that a large portion of respondents consider local residents and municipalities responsible for natural resource conservation, active community participation in decision-making and resource management should be encouraged.
Monitoring Emerging Environmental Challenges
As pollution, environmental degradation, and climate change are identified as the main challenges, it is recommended to establish monitoring and reporting mechanisms for these issues, along with developing adaptation and prevention strategies.
Encouraging Willingness for Sustainable Changes in Individual Habits
Considering participants' willingness to modify their habits to protect natural resources, it is important to create policies and incentives that support sustainable behavioral changes.

Abstract

Induction of labor is a frequent obstetric intervention, yet its impact on maternal and neonatal outcomes remains debated. This study evaluated maternal and neonatal outcomes after induction of labor at term and contextualized the findings within contemporary international evidence. A retrospective analysis was conducted on 400 term pregnancies undergoing induction. Maternal variables included parity, Bishop score, intrapartum complications, and mode of delivery, while neonatal outcomes included Apgar scores, serious diagnoses, need for resuscitation, and NICU admission. Most women (92%) presented with a favorable Bishop score (≥6), and 273 women (68.3%) experienced no intrapartum complications. The most frequent complications were perineal rupture (53 cases) and umbilical cord–related events (51 cases). A total of 373 women (93.2%) delivered vaginally, whereas 27 (6.8%) required cesarean section, primarily due to ineffective induction or fetal distress. Neonatal outcomes were highly reassuring: 394 newborns (98.3%) had no serious diagnosis, only one infant had an Apgar score ≤3, one intrauterine fetal death occurred, and NICU admission was required in only one case (0.2%). Overall, induction of labor at term when performed for appropriate obstetric indications and supported by standardized monitoring was associated with low maternal complication rates, a very low cesarean rate, and excellent neonatal outcomes, supporting its role as a safe and effective strategy to prevent deterioration of maternal-fetal conditions when indicated.

Keywords: induction of labor, maternal outcomes, neonatal outcomes, cesarean delivery, bishop score

INTRODUCTION

Labor induction refers to the artificial initiation of uterine contractions with the purpose of achieving vaginal birth before the spontaneous onset of labor (ACOG, 2020). It is generally undertaken when the risks of continuing pregnancy outweigh the potential risks associated with induction. Common clinical indications include post-term pregnancy, hypertensive disorders of pregnancy, oligohydramnios, premature rupture of membranes, gestational diabetes, and intrauterine growth restriction (IUGR) (Caughey et al., 2022; World Health Organization [WHO], 2022). The decision to induce labor must therefore balance maternal and fetal risks while considering cervical readiness, typically assessed through the Bishop score.

Several induction methods exist, ranging from pharmacological techniques, such as prostaglandins (misoprostol, dinoprostone) and oxytocin, to mechanical approaches, including Foley catheter or double-balloon catheter insertion (Sheldon & Diedrich, 2021). Combined methods are often employed to improve cervical ripening and enhance the success of vaginal delivery. Evidence suggests that mechanical methods are associated with lower rates of uterine tachysystole, whereas prostaglandins may be more effective for cervical ripening in unfavorable cervices (Ten Eikelder et al., 2019).

In recent years, attention has increasingly focused on the outcomes of elective induction, especially at 39 weeks of gestation. Findings from large randomized trials and meta-analyses such as the ARRIVE Trial by Grobman et al. (2018) demonstrate that elective induction at 39 weeks may reduce the risk of cesarean delivery and hypertensive complications without increasing adverse neonatal outcomes. Subsequent analyses have supported

these observations, suggesting improved perinatal safety when induction is performed under standardized protocols and continuous monitoring (Walker et al., 2020; Stock & Norman, 2021). Despite this, controversy persists because results vary across populations, resource settings, and institutional practices.

Concerns frequently raised in the literature include the potential for increased medical interventions, prolonged labor, and higher use of analgesia among induced women (Boulvain et al., 2016). Conversely, expectant management may increase the likelihood of stillbirth, meconium aspiration, or neonatal morbidity in late-term and post-term pregnancies (Muglu et al., 2019). These conflicting findings underscore the importance of evaluating induction outcomes in diverse clinical settings.

Against this background, the present study aims to assess the maternal and neonatal outcomes among 400 women who underwent labor induction, as documented in the dataset. By comparing these findings with contemporary international evidence, this study seeks to determine whether induction of labor is associated with improved or worsened perinatal outcomes relative to spontaneous labor or expectant management. Ultimately, the goal is to contribute data-driven insights to the ongoing debate surrounding the safety, efficacy, and clinical appropriateness of labor induction.

MATERIALS AND METHODS

Study design and population

This study employed a retrospective observational design, analyzing clinical data from a cohort of 400 pregnant women who underwent induction of labor at term. All cases were extracted from institutional obstetric records and represented consecutive admissions during the study period. The dataset included information obtained from maternal electronic charts, intrapartum monitoring sheets, and neonatal outcome documentation, ensuring a complete overview of both maternal and neonatal parameters. Women with multiple gestations, major fetal anomalies, or incomplete medical records were excluded to preserve data consistency. The study population consisted of both primiparous and multiparous women, reflecting the parity structure presented in the institutional registry. Gestational age at the time of induction ranged from 38 to 41 weeks, consistent with the distribution illustrated in the uploaded report.

Induction procedures

Labor induction in this cohort was performed according to institutional protocols and international clinical guidelines. Several induction modalities were used, selected based on cervical favorability, maternal–fetal status, and clinical indications recorded prior to the procedure.

Pharmacological induction included the administration of oxytocin, initiated at a low dose of 1–2 mU/min with gradual titration every 30-40 minutes until adequate uterine activity defined as three to five contractions every ten minutes was achieved. Prostaglandin preparations (PGE1 or PGE2) were administered for cervical ripening, particularly in women presenting with an unfavorable Bishop score. Misoprostol or dinoprostone formulations were used in accordance with their respective dosing protocols specified in the clinical guidelines of the institution. Mechanical methods, such as the Foley catheter or double-balloon catheter, were applied in selected cases requiring mechanical cervical dilation, especially when prostaglandins were contraindicated or when the cervix was markedly unripe. In certain patients, combined approaches (e.g., prostaglandins followed by oxytocin augmentation) were employed to increase the likelihood of successful induction. All women underwent continuous fetal and maternal monitoring throughout the induction process, as per standard obstetric safety requirements.

Variables and outcome measures

Maternal and neonatal variables were identified based on availability in the clinical records and relevance to induction outcomes. Maternal variables included parity, Bishop score prior to induction, mode of delivery, and intrapartum complications. Complications were categorized into predefined groups such as perineal rupture, umbilical cord complications, hypertensive crises, cervical lacerations, and other obstetric events documented in real time by clinical staff. Mode of delivery was classified as spontaneous vaginal birth, instrumental delivery, or cesarean section, accompanied by the documented clinical indication (e.g., failed induction, fetal distress).

Neonatal outcome measures included Apgar scores at 1 and 5 minutes, presence of serious neonatal diagnoses, requirement for neonatal resuscitation, and admission to the Neonatal Intensive Care Unit (NICU). Data on fetal

demise, birth trauma, and other immediate postnatal complications were also collected. These variables allowed for a comprehensive assessment of perinatal safety following induction of labor.

Data analysis
A descriptive statistical approach was employed to evaluate the distribution of maternal and neonatal outcomes. Frequencies and proportions were calculated for categorical variables, while continuous variables (e.g., maternal age) were summarized using appropriate descriptive measures. Results obtained from the 400-case cohort were interpreted in relation to contemporary global literature published between 2019 and 2025, as summarized in the uploaded presentation. Comparative interpretation emphasized alignment or divergence between local institutional outcomes and findings of recent systematic reviews, randomized controlled trials, and meta-analyses addressing labor induction and perinatal safety. The analytical goal was not inferential hypothesis testing, but rather contextualization of observed patterns within the broader evidence base.

RESULTS

This study analyzed a total of 400 women undergoing induction of labor. The results describe maternal demographic characteristics, obstetric history, clinical indications for induction, intrapartum complications, delivery outcomes, and neonatal conditions. Figures and tables provided illustrate the quantitative distribution of each variable.

Maternal demographics

Figure 1 presents three key demographic and obstetric characteristics of the study population: age distribution, parity/gravida, and number of previous births.

The age distribution (Figure 1, left panel) shows that the majority of women undergoing induction of labor were between 24 and 35 years old. The highest concentration of patients was observed in the 25–28-year age group, representing the predominant reproductive-age population in this cohort. A smaller proportion of women were younger than 22 or older than 40 years, indicating that inductions were primarily performed among women in low- to moderate-risk age categories.

The parity distribution (Figure 1, center panel) demonstrates that multiparous women constituted the larger share of the sample. Specifically, approximately 260 women were multiparas, compared with about 140 primiparas. This 2:1 ratio suggests that induction was more commonly performed among women with prior childbirth experience. The predominance of multiparas is clinically relevant, as parity is strongly associated with cervical readiness and higher likelihood of successful vaginal delivery following induction.

The distribution of previous births (Figure 1, right panel) shows that most multiparous women had one or two prior deliveries, representing the largest portion of the histogram. A moderate number had three previous births, while cases of grand multiparity (≥4 births) were relatively uncommon. Only isolated cases were noted with 5, 6, or 7 prior births. This pattern indicates that the study population largely consisted of women with low to moderate parity levels, supporting a favorable obstetric risk profile and contributing to the overall success of induction outcomes.

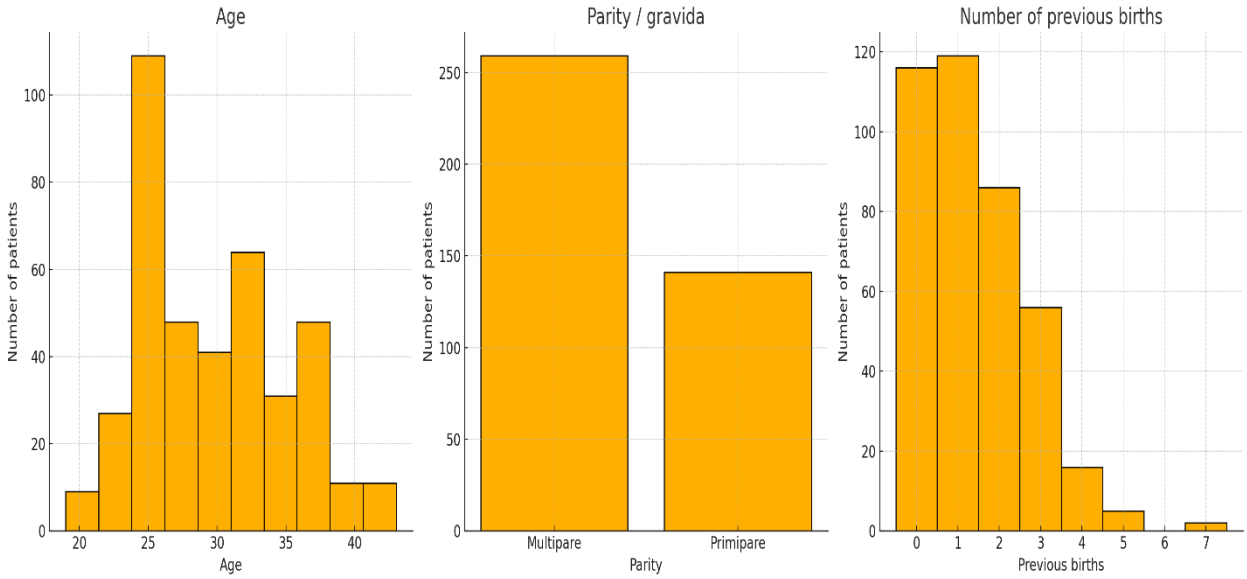

Figure 1. Age, Parity/Gravida, and Number of previous births

Gestational age at induction

Gestational ages ranged from 38.0 to 41.0 weeks. As shown in Figure 2, inductions peaked between 39 and 41 weeks, representing the majority of procedures. Only 9 cases were recorded at 38 weeks.

This distribution is consistent with international guidelines that recommend induction in late-term and early post-term pregnancies or when maternal-fetal complications arise.

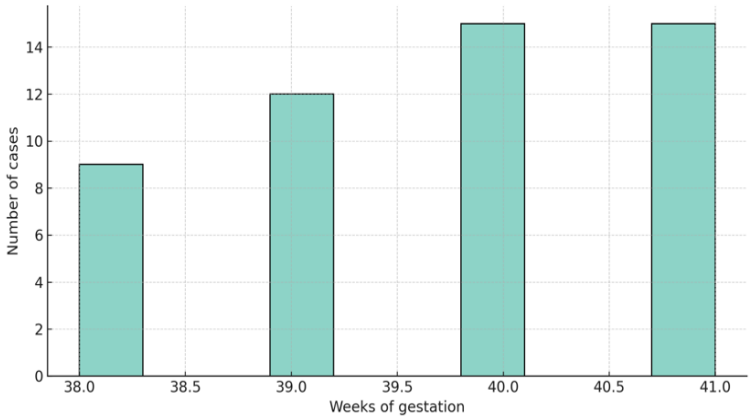

Figure 2. Gestational weeks at time of induction

Cervical readiness

The figure depicts cervical readiness assessed by the Bishop score. A substantial majority (92%) had a favorable score (≥6), suggesting a high likelihood of successful induction and lower risk of operative delivery. Only 8% demonstrated unfavorable cervical conditions, which typically predict longer induction times and increased need for augmentation. This distribution reflects strong candidate selection and contributes to the favorable outcomes observed in the study.

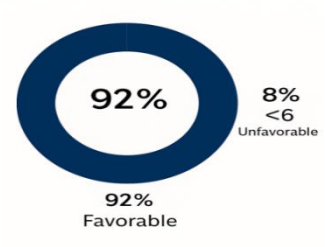

Figure 3. Bishop Score before induction

Intrapartum complications

Figure 4 presents the distribution of intrapartum complications among the study population. Most patients (273; 68.3%) experienced no complications during labor, demonstrating a favorable maternal safety profile associated with induction. The most frequent complications were perineal rupture (53 cases) and umbilical cord-related events (51 cases). Other complications, including cervical laceration, vaginal hematoma, pre-eclampsia, PIH syndrome, and anal sphincter rupture occurred at very low frequencies (1–3 cases each). These findings indicate that, although complications may arise during induced labor, their overall incidence in this cohort was low and within acceptable clinical ranges.

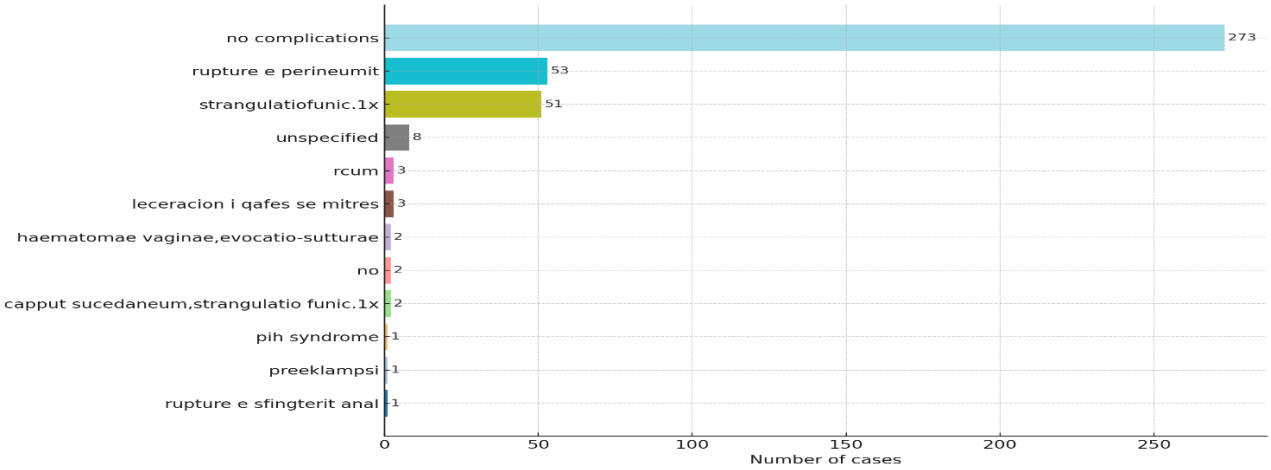

Figure 4. Complications during labor

Parity distribution and indications for induction

Figure 5 summarizes key baseline characteristics of the induced population. The parity distribution shows that multiparous women comprised the majority (65%), while primiparous women represented 35%. This is clinically relevant because multiparous women generally exhibit more favorable cervical conditions and higher induction success rates.

When interpreted together with the indications for induction, the data demonstrate that most inductions were medically warranted, with post-term pregnancy being the leading indication, followed by placenta previa, PIH syndrome, and meconium-stained fluid. The fact that a largely multiparous population required induction for these conditions suggests that many of the patients had prior childbirth experience but developed new pregnancy-related complications necessitating timely intervention.

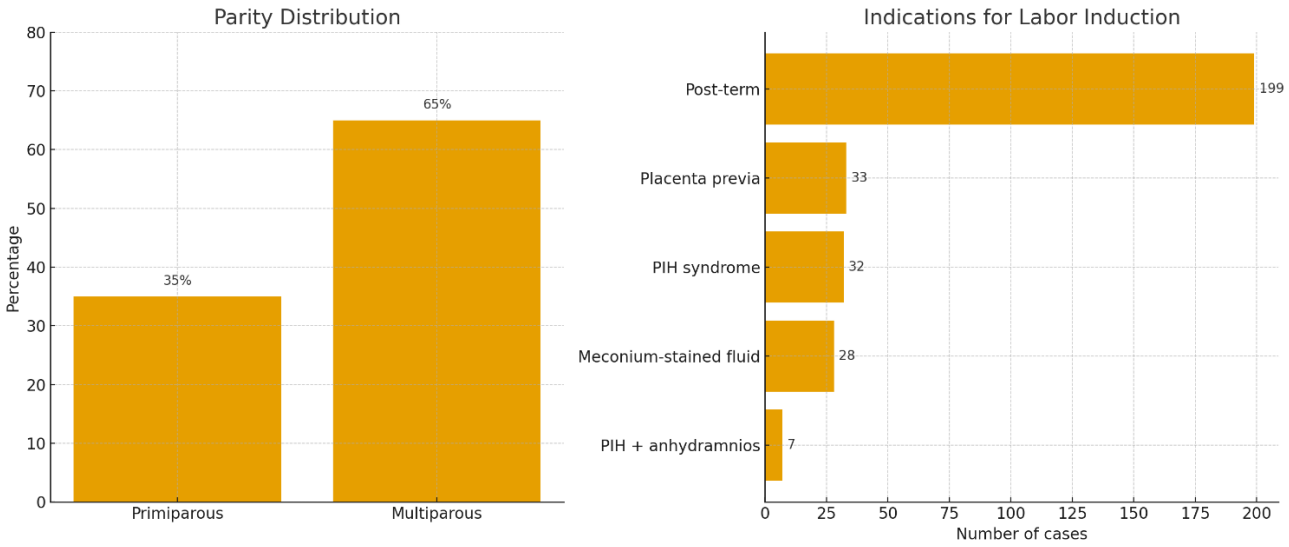

Figure 5. Parity distribution and Indications for labor induction

Maternal complications and delivery outcomes

Figure 6 presents a combined overview of maternal intrapartum complications and delivery outcomes following labor induction.

On the left, the chart shows that most women experienced no maternal complications during labor (273 cases; 66.9%), while 31.1% experienced some form of complication (127 cases). Only a small proportion (2%) was classified as "not specified." This distribution reflects a generally safe intrapartum course, with complications occurring in a minority of cases.

On the right, the figure demonstrates that the vast majority of induced labors resulted in vaginal delivery. Only 27 women (6.8%) underwent cesarean section, while 93.2% delivered through other (non-operative) modes. This very low cesarean rate aligns with the high proportion of women who had favorable cervical conditions and few complications.

Together, these two panels emphasize the overall safety and effectiveness of labor induction in the study population, showing low rates of complications and an excellent vaginal delivery success rate.

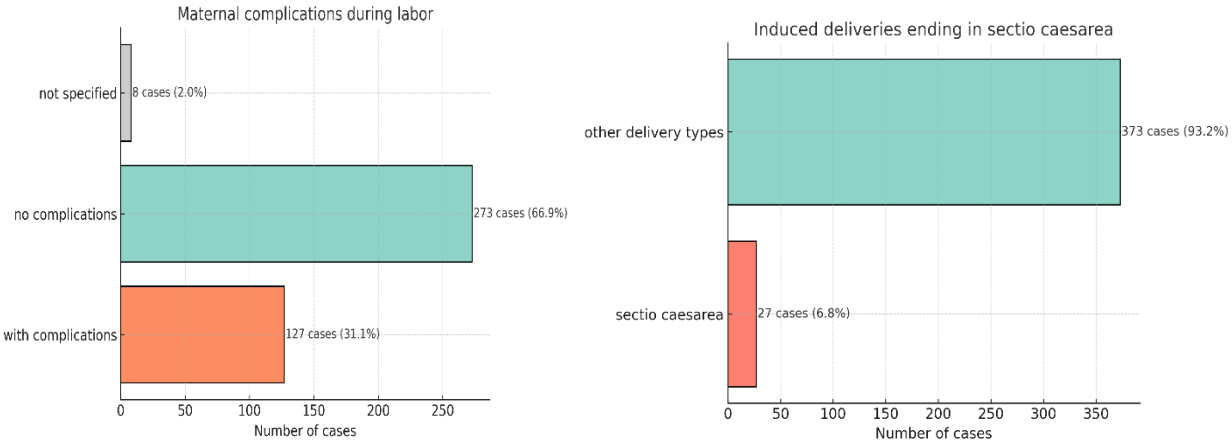

Figure 6. Maternal complications during labor Induced deliveries ending section caesarea

Clinical indications for cesarean section

Figure 7 shows the main reasons for cesarean section after labor induction. The most common indication was ineffective induction (20 cases), followed by fetal distress (6 cases). Only one case was attributed to abnormal

fetal presentation. Overall, the results indicate that most cesarean deliveries occurred due to inadequate labor progression rather than severe maternal or fetal complications.

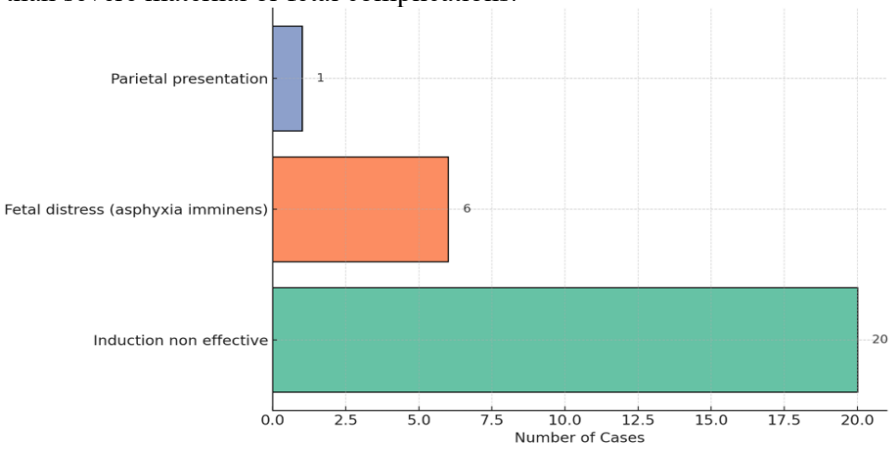

Figure 7. Clinical Indications for Cesarean Section After Induction

Maternal complications, cesarean distribution, and neonatal outcomes

These figures demonstrate a consistent pattern: maternal complications were uncommon (Figure 8), cesarean delivery was more influenced by primiparity than by complications (Figure 9), and neonatal outcomes were highly favorable across all groups (Figure 10). These findings suggest that the induction process was generally safe and effective, with limited adverse maternal or neonatal events.

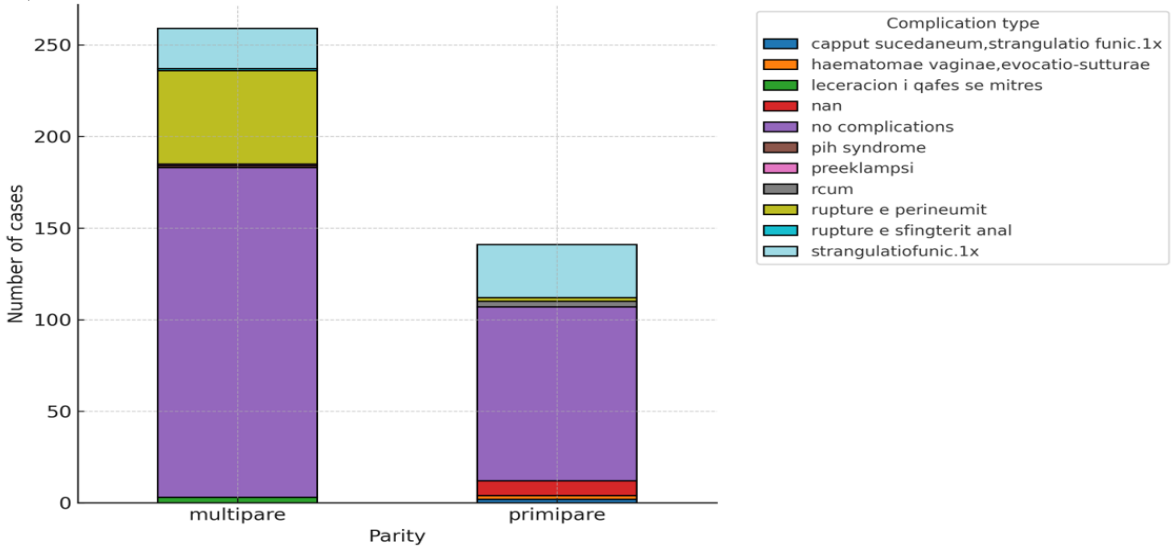

Figure 8. Parity vs. maternal compications during labor

Figure 8 illustrates the relationship between parity and maternal complications during labor. In both primiparous and multiparous women, the majority experienced no complications, although the absolute number of complications was higher among multiparas due to their larger representation in the study population. Overall, maternal complications were relatively infrequent in both groups.

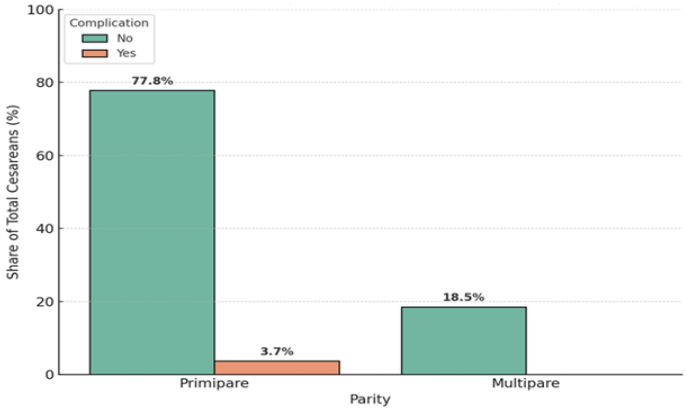

Figure 9. Cesarean distribution by parity and complication group

Figure 9 examines how parity and the presence of complications relate to cesarean section rates. The majority of cesarean deliveries occurred among primiparous women without complications (77.8%), while only a small proportion occurred in multiparas. This suggests that parity itself rather than intrapartum complications, was a stronger contributor to cesarean delivery risk in this cohort.

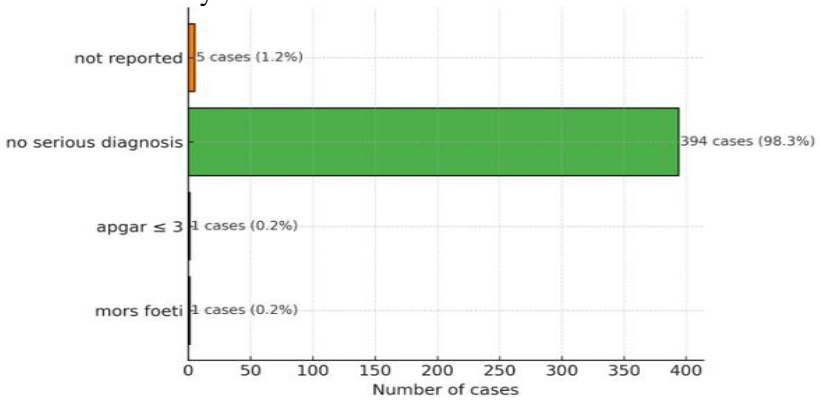

Figure 10. Neonatal serious diagnoses

Figure 10 presents neonatal outcomes, showing overwhelmingly favorable results. The vast majority of newborns (98.3%) had no serious diagnosis, with only isolated cases of low Apgar score or fetal death. Importantly, neonatal complications remained rare regardless of maternal parity or the occurrence of maternal complications.

DISCUSSION

This study provides a comprehensive overview of maternal and neonatal outcomes following induction of labor in 400 term pregnancies. Overall, the findings indicate that appropriately indicated and carefully monitored induction is a safe and effective intervention in this setting.

Maternal outcomes

The high proportion of women with a favorable Bishop score (92%) reflects good clinical selection for induction and likely explains, in part, the very low cesarean section rate of 6.8%. In many randomized trials and large cohort studies, cesarean rates after induction range from 15–25% or higher, depending on parity and cervical status (Grobman et al., 2018; Ten Eikelder et al., 2019). The lower rate in our population suggests that strict attention to cervical readiness and protocolized oxytocin titration can substantially reduce the likelihood of operative delivery. Most women (68.3%) experienced no intrapartum complications, and those that did occur were predominantly perineal ruptures and umbilical cord events, which are common in obstetric practice and mostly self-limiting. Serious events such as severe genital tract trauma, hypertensive crises, or anal sphincter rupture were exceedingly rare, supporting previous evidence that medically indicated induction does not inherently increase maternal

morbidity compared with expectant management when guideline-based monitoring is in place (ACOG, 2020; Sheldon & Diedrich, 2021).
Parity patterns also contributed to this favorable profile. The cohort was predominantly multiparous (65%), and parity is known to correlate with shorter labors, better cervical favorability and higher vaginal delivery rates. Nonetheless, detailed analysis showed that primiparity itself was a stronger driver of cesarean delivery than the presence of intrapartum complications, consistent with international data identifying primiparous women as a key group at higher risk of operative birth (Boulvain et al., 2016; Caughey et al., 2022).
Neonatal outcomes
Neonatal outcomes in this cohort were excellent. Almost all newborns (98.3%) were discharged without serious diagnosis; only a single infant had a low Apgar score and one intrauterine fetal death was recorded. NICU admission was required in only one case. These figures are at least comparable—and in some instances more favorable—than those reported in large trials of elective or indicated induction at term, where induction has been associated with stable or improved neonatal outcomes when compared with expectant management (Grobman et al., 2018; Stock & Norman, 2021; Walker et al., 2020).
Importantly, many inductions in this cohort were performed for conditions that themselves increase perinatal risk, including post-term pregnancy, hypertensive disorders and meconium-stained fluid. The absence of excess neonatal morbidity despite these indications supports the notion that induction can mitigate, rather than exacerbate, the risks associated with prolonged pregnancy or evolving maternal–fetal compromise (Muglu et al., 2019; WHO, 2022).
Comparison with existing literature
Our results are broadly consistent with contemporary evidence suggesting that induction at or beyond 39 weeks can reduce rates of cesarean delivery and hypertensive complications without increasing adverse neonatal outcomes (Grobman et al., 2018; Walker et al., 2020). The particularly low cesarean rate in this study compares favorably even with the ARRIVE trial and may reflect context-specific factors such as:
high prevalence of favorable Bishop scores
predominance of multiparous women
adherence to an institutional culture that prioritizes vaginal birth where safe
At the same time, the findings reinforce meta-analytic data indicating lower stillbirth and perinatal mortality with planned induction beyond 39 weeks compared with expectant management (Muglu et al., 2019).
Clinical implications
From a clinical standpoint, these results highlight several key points:
Careful selection and preparation-particularly assessment of cervical favorability are central to maximizing induction success and minimizing cesarean delivery.
Standardized protocols for oxytocin administration, prostaglandin use and mechanical methods, coupled with continuous fetal and maternal monitoring, can maintain a very low rate of serious complications.
Primiparous women remain the subgroup at highest risk of cesarean section; they may benefit most from individualized counseling, closer labor surveillance and, where appropriate, early cervical ripening strategies.

CONCLUSION

In this cohort of 400 term pregnancies, induction of labor carried out according to standardized institutional protocols and for clearly defined obstetric indications was associated with a favorable maternal and neonatal safety profile. Nearly 70% of women experienced no intrapartum complications, serious maternal morbidity was rare, and the overall cesarean section rate was notably low at 6.8%. These findings indicate that, when cervical readiness is appropriately assessed and clinical decision-making is optimized, induction of labor does not inherently increase the likelihood of operative delivery.
Neonatal outcomes were similarly reassuring. More than 98% of newborns had no serious clinical diagnosis, the need for resuscitation or NICU admission was minimal, and perinatal mortality was very low. This is particularly important given that many women in the cohort had conditions known to increase perinatal risk, such as post-term pregnancy and hypertensive disorders, yet no meaningful excess of adverse neonatal events attributable to induction was observed.
Overall, this study supports the judicious use of labor induction as a safe and effective component of modern obstetric practice, especially in late-term and post-term pregnancies or when maternal–fetal status warrants timely delivery. Induction should not be viewed as an intervention that inherently elevates risk but rather as a valuable

strategy when individualized to gestational age, cervical status, and patient-specific risk factors. Future prospective, comparative studies including cohorts with spontaneous onset of labor are warranted to further refine patient selection, optimize induction protocols, and clarify the balance between induction and expectant management across different healthcare settings.

ORAL PRESENTATION

Environmental evaluation of outdoor pollen and its association with allergic asthma in a population group

Brikena Muja (Parllaku), Etleva Hamzaraj, Mirela Lika (Çekani)

Department of Biology, Faculty of Natural Sciences, University of Tirana, Boulevard "Zogu i Parë", no. 25/1, 1001 Tirana, Albania

Abstract

Outdoor pollen is a major environmental trigger of allergic asthma, with seasonal peaks strongly linked to increased respiratory symptoms, medication use, and emergency healthcare visits. This study evaluates outdoor pollen concentrations and examines their association with allergic asthma in a defined population group. Aerobiological monitoring was conducted using standardized volumetric sampling, while clinical and epidemiological data were collected from symptom diaries, patient records, and healthcare reports. The study of allergic asthma by immunological methods, and the determination of pollens as allergens is important in determining the diagnosis and avoiding, or treating, asthma. These allergens contact our body through the skin, airways and food. Pollen enters the lungs through the air and meets the mucous membranes of the nose, throat and bronchi. It has been noticed that the presence of allergens such as pollen in our country is very high. Meteorological variables were analyzed to understand environmental interactions. Findings indicate a strong correlation between elevated pollen levels—particularly from grasses and selected weed species—and increased asthma exacerbations and symptom severity. The study emphasizes the importance of integrated pollen monitoring, early-warning systems, and targeted public health strategies to reduce exposure and improve disease management for individuals affected by pollen-induced asthma. Through biostatistical analyses we have seen the association of allergic asthma in relation to their age group, gender and place of residence.

Keywords: Allergic asthma, pollen, pollution, immune test, allergies, public health

Introduction

Allergic asthma is a chronic inflammatory condition of the airways characterized by episodes of wheezing, dyspnea, chest tightness, and coughing triggered by exposure to specific allergens. Allergy is a disease which is related to immunological reactions, which are carried out in the body and because of an inflammation appear clinical signs such as: redness, swelling, itching, etc. It depends on several factors such as age, gender, lifestyle and genetic predispositions (Brehler & Kütting, 2001; Griffiths & Ducharme, 2013). Asthma is a long-term inflammatory disease of the airways of the lungs (Martinez, 2007; Scott & Peters-Golden 2013).

Outdoor pollen remains one of the most potent and widespread environmental triggers, affecting millions of sensitized individuals globally. Pollen grains, released seasonally by trees, grasses, and weeds, contain allergenic proteins capable of provoking strong IgE-mediated immunological responses upon inhalation. In sensitized individuals, this leads to airway inflammation, bronchial hyperresponsiveness, and acute asthma symptoms. It is characterized by variable and recurring symptoms, reversible airflow obstruction, and easily triggered bronchospasms (Kumar *et al*., 2010; Robbins & Cotran, 2010). Symptoms include episodes of wheezing, coughing, chest tightness, and shortness of breath (Anandan *et al*., (2010); Manniche, 1999). These may occur a few times a day or a few times per week (Cox *et al.,* 2008; Parsons *et al*., 2013). Depending on the person, asthma symptoms may become worse at night or with exercise (Cox *et al*., 2008).

The distribution and concentration of outdoor pollen vary across regions due to climate, vegetation, and meteorological factors. Climate change has intensified these effects, contributing to earlier and longer pollen seasons, increased pollen productivity, and elevated allergenic potency. These changes raise significant public health concerns, particularly for populations already vulnerable to respiratory disorders. Asthma is thought to be caused by a combination of genetic and environmental factors (Griffiths & Ducharme, 2013; Lemanske *et al*.,

2010). Environmental factors include exposure to air pollution and allergens (Teoh *et al*., 2012; Yawn, 2008). Other potential triggers include medications such as aspirin and beta blockers (Murray & John, 2010). Diagnosis is usually based on the pattern of symptoms, response to therapy over time, and spirometry lung function testing (Parsons *et al*.,2013). Asthma is classified according to the frequency of symptoms, forced expiratory volume in one second (FEV1), and peak expiratory flow rate (Teoh *et al*., 2012). It may also be classified as atopic or non-atopic, where atopy refers to a predisposition toward developing a type 1 hypersensitivity reaction (Martinez, 2007; Vézina *et al*., 2014).

Existing literature demonstrates consistent associations between high outdoor pollen counts and increased asthma morbidity. However, the strength of this relationship varies by region, vegetation type, air quality, and socio-demographic characteristics. Air pollutants may interact synergistically with pollen, enhancing allergenic activity and worsening respiratory outcomes. Despite substantial global evidence, many local communities lack integrated monitoring systems that combine pollen data with clinical indicators. In most cases it happens that some people who have skin irritations or redness, classify it as allergy or vice versa. All this comes because of not performing diagnostic tests and not being aware of these diseases. (Rusznak *et al*.,1998; Scott &Peters-Golden, 2013).

The present study aims to evaluate outdoor pollen concentrations and their association with allergic asthma in a defined population. The objectives of this study are to: characterize seasonal pollen variability, assess asthma symptom patterns in relation to pollen exposure, identify specific pollen types most strongly linked to asthma exacerbations, and evaluate meteorological influences on pollen levels and asthma outcomes. The findings aim to guide environmental health planning, improve clinical management strategies, and strengthen public health preparedness.

An allergic response occurs when immune system proteins (antibodies) mistakenly identify a harmless substance, such as tree pollen, as an invader. To protect your body from the substance, antibodies bind to the allergen (Holgate, 1998; Janeway *et al*., 2001).

The chemicals released by your immune system led to allergy signs and symptoms, such as nasal congestion, runny nose, itchy eyes or skin reactions (Fig, 3). For some people, this same reaction also affects the lungs and airways, leading to asthma symptoms (Vézina *et al*., 2014; Yawn, 2008).

Materials and Methods

In this study, biological samples were collected and taken, according to the relevant procedures and stored according to appropriate conditions. During the period January -November 2024, 100 blood samples suspected of the presence of allergens were analyzed, where 59 came out positive and they received the appropriate treatment.

Two methods were used to achieve the objectives of our study:

(1) Alleisascreen Tec (MEDWISS Analytic GmbH); (2) Surveys.

The AlleisaScreen test is a very simple test to use. It is a test that analyzes blood serum and is not applied directly to the skin thus avoiding side effects (Figure 4). This test measures the amount of IgE antibodies formed as a result of a suspected allergen using a series of allergens in its composition. There are 30 types of allergens on the panel, so with a single analysis we can detect a series of allergens, which affect us in different seasons and at different times of the year. It measures the amount of IgE with the unit of measurement iU/ml; as well as measuring food and inhaler allergens. The first step is to take the blood of a person who is suspected of having allergies. Once the blood is taken, the normal procedure for obtaining blood serum is performed.

The procedure for assessing the present allergens is done by several methods: Improvio scanners, CubeScreen Reader or RapidReader. Concentration of Immunoglobulin IgE in our sample is done by dividing into several classes or ranks.

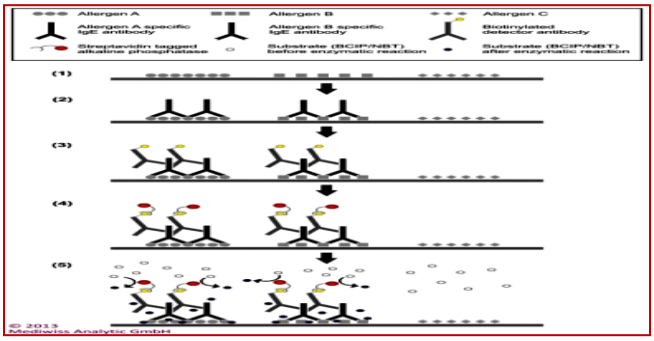

Figure 1. The scheme of action of pollen with IgE antibodies in a Allesiascreen test

Realization and discussion

Outdoor pollen has long been recognized as a key environmental factor influencing asthma prevalence and severity. Studies across Europe, North America, and Asia demonstrate clear seasonal patterns of asthma exacerbations that coincide with peak pollen release from regional vegetation. Grass pollen is frequently identified as one of the most potent asthma triggers, while certain tree and weed pollens also contribute significantly depending on geographical context.

Air pollution interacts with pollen allergens, modifying their protein structures and increasing airway vulnerability. Particulate matter and ozone have been shown to intensify allergic respiratory responses, creating synergistic health impacts. Despite these insights, localized studies remain essential, as pollen composition, meteorological trends, and exposure risks differ substantially across regions.

The observed data were presented in mean value and in standard deviation. Discrete data were presented in absolute value and in percentage. The data were presented by means of tables and graphs of different types, type diagrams and surface diagrams. SPSS statistical package is used for data analysis. After application of the Alleisascreen test, most patients tested positive for one or more pollens, with varying degrees of positivity.

Table 1. Comparison of age groups in relation to cases of allergies

Age Groups	No. of cases	Percentage	Cum.
10-15 years old	47	91%	91%
16-24 years old	12	7.5%	98.5%
< 25 years old	7	1.5%	100.00%
Total	66	100.00%	

In Table 1, in the three groups of age 10-15 years, 16-24 years and more than 25 years old, an unequal number of patients with allergies is observed. The largest number of cases is observed in the first age group from 10-15 years, with 91% of cases, the second age group with 7.5% and the third age group with 1.5% of the sample.

In figures from 2 to 6 are presented the main tree which produced pollen, the causer of alergic asthma in Tirana. In our study, the number of women who underwent Allesisascreen surgery was higher than that of men (54% compared to 46% of men).

The age group most affected by any type of allergy is the first one, which includes children. Even from a study the most affected age group is that of children with twice the cases of adults (Lemanske et al., 2010). This is due to the complete failure of the immune system and the signs of the appearance of these symptoms such as irritation, rash to asthma are more frequent and more evident in children.

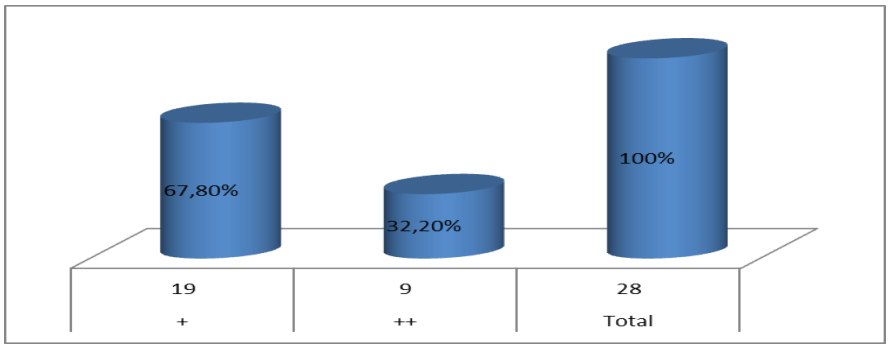

Figure 7. Division of cases according to the degree of presence of the allergen.

From the Figure 7 above we see that in 67.8% of cases we have a mild allergy, which appears with slight irritation while in 32% of cases of the tested we have a high presence of allergens. + (low presence), ++ (high presence)

Allergic asthma is very common and out of 100 individuals taken for analysis 70 of them have come to perform a test related to allergic asthma. Out of 70 individuals analyzed, 38 were positive.

Of the 38 individuals analyzed 8 are positive males and 30 are female (Table 3). So, it is obvious that women are more affected by the surveys done. This also comes as a result of the care they have for themselves by not letting an irritation pass as a common symptom.

Table 3. The degree of positivity in allergen-positive patients

Alesiascreen test positivity rate Allergic Asthma	Number of positive cases	Percentage in the group
+	32	84%
++	6	16%
Total	38	

Each analysis performed has a degree of presence of the allergen. With a (+) we will denote the lowest degree of presence of the allergen, with two (+) we will denote the highest degree of the presence of the allergen. From the analyzes performed, our test manages to capture even the lowest degree of allergen, so we have divided them into several categories: not at all or little present [0.00-0.34 IU / ml], minimum limit [0.35-0.69 IU / ml], low presence

[0.70-3.49 IU / ml] sensitive presence [3.50-17.49 IU / ml], high [17.5-49.9 IU / ml], very high [50.0-100.0 IU / ml]. But since in the tests performed the low presence and sensitive presence groups were dominant, we divided them into 2 large groups.

From the table above we have marked with (+) the low degree of allergic asthma and with (++) the high degree. 84% of cases are in the low rate, while 16% are in the high rate.

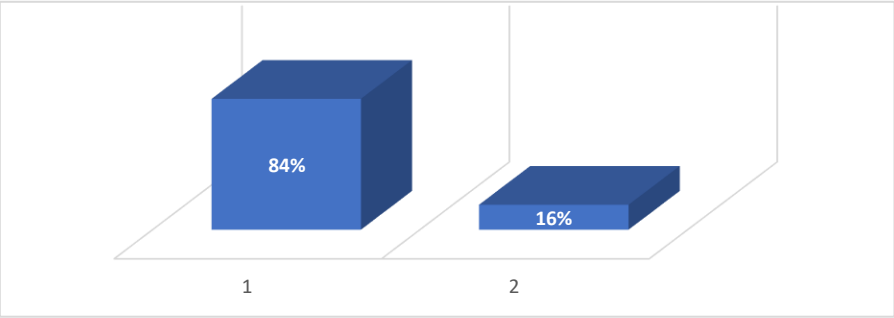

Figure 8. The degree of positivity of cases with allergies.

From the figure 8, we see that the number of cases with a low rate of allergic asthma constitute the largest number with 32 cases (84%) and those with a high rate of allergies account for 6 cases (16%).
To observe the relationship that exists between gender and allergic asthma, we will use a statistical test $\chi 2$ since we have qualitative variables presented in Table 4. In this test on Table 5, what is important is the significance value, which indicates the accuracy of the test.

Table 4. The χ^2 link between gender and allergic asthma cases

		Allergic asthma cases		
		Yes	No	Total
Gender	Female	41	13	54
	Male	25	21	46
Total		66	34	100

Table 5. The Signifivance value

	Value	Df	Asymp. Sig. (2-sided)	Exact Sig. (2-sided)	Exact Sig. (1-sided)
Pearson Chi-Square	5.154[a]	1	0.023		
Continuity Correction[b]	4.237	1	0.040		
Likelihood Ratio	5.177	1	0.023		
Fisher's Exact Test				0.034	0.020
Linear-by-Linear Association	5.1031		0.024		
N of Valid Cases	100				

Test value $X^2_{(1)}=5.154;p=0.023$
Since $p < 0.05$, then gender is related to allergic asthma.

The results support existing evidence that outdoor pollen plays a significant role in triggering allergic asthma. The observed seasonal variations highlight the importance of monitoring pollen distribution and preparing targeted health interventions during peak exposure periods.

Grass pollen, identified as the primary contributor to asthma exacerbations in this study, aligns with global research demonstrating its high allergenic potential. The correlation between meteorological patterns and pollen levels further emphasizes the need for environmental surveillance systems capable of forecasting high-risk periods.

Public health strategies should incorporate pollen warnings, patient education, and preventive clinical measures to reduce exposure and mitigate asthma severity. Integration of pollen data with digital health technologies may support personalized asthma management and improve outcomes.

In conclusion we can say:

This study demonstrates a significant association between outdoor pollen levels and allergic asthma outcomes in the studied population. The findings highlight the importance of integrated pollen monitoring, environmental forecasting, and targeted public health strategies to reduce exposure and improve disease management. Enhanced aerobiological surveillance and better integration of clinical data can strengthen early-warning systems and support more effective interventions for individuals with pollen-induced asthma.

Abstract

The corrosion behavior of carbon steel in a CO_2-saturated environment was investigated using the Tafel polarization method in the presence of 10% solutions (prepared in 70% isopropyl alcohol) of amino complexes and their corresponding salts synthesized from the first fraction of natural petroleum acids. The experiments were carried out using a "CorrTest" electrochemical potentiostat in a 1% sodium chloride (NaCl) solution saturated with CO_2 at a pressure of 0.9 bar, a temperature of 50°C, and a duration of 1 hour. The aim of the study was to evaluate the inhibitive performance of the newly synthesized reagents and to elucidate the structure–property relationship governing their protective capabilities. In the uninhibited sample, the corrosion rate was 0.675 mm/year, confirming the highly aggressive nature of the CO_2-saturated medium and the necessity for an efficient corrosion inhibitor. Comparative analysis of the synthesized complexes showed that the N-1 compound (butylamine complex) exhibited the highest protective activity. At a concentration of 1000 ppm, it achieved 98.8% inhibition efficiency and reduced the corrosion current density (Icorr) to 5.763×10^{-7} A/cm², indicating strong adsorption and effective surface coverage on the metal. The N-2 complex (octylamine derivative) demonstrated 84.9% efficiency, attributed to the increased hydrophobicity provided by its long alkyl chain, which facilitated the formation of a partially compact barrier layer. The N-3 complex (diethylamine derivative) showed 92.5% inhibition efficiency, suggesting that both electronic and steric effects influence its adsorption behavior. The N-4 complex (dibutylamine derivative) provided approximately 75% protection; however, its performance decreased due to weaker adsorption associated with the spatial configuration of the molecule, which likely hindered the formation of a uniform protective film.

Keywords: carbon steel corrosion, CO_2 corrosion, amino complexes, corrosion inhibitors, Tafel polarization, adsorption mechanism

Introduction

In most subsea developments, oil and gas production is transported from the subsea well to the platform in a multiphase flow without a separation process. Corrosion is a growing problem in the operation of subsea pipelines. Corrosion can be defined as the deterioration of a metal due to chemical or electrochemical reactions between the metal and the surrounding environment [9]. The susceptibility of a metal to corrosion depends on the environment and the type of metal. The presence of carbon dioxide (CO_2), hydrogen sulfide (H_2S), and free water in the production fluid can cause severe corrosion problems in oil and subsea pipelines. Integrity and risk management of internal corrosion in wells and pipelines depends on temperature, CO_2 and H_2S content, water chemistry, flow rate, oil or water wetting, as well as the composition and condition of the steel surface [1-3].

Corrosion-resistant alloys, such as 13% chromium steel and duplex stainless steels, are often used in well tubing, subsea manifolds, and structures. However, for long-distance pipelines, carbon steel remains the only economically viable option, and corrosion must be controlled, with pipelines protected from both internal and external corrosion. This article discusses the development of predictive models for corrosion defects and the reliability-based design and reassessment criteria for evaluating corroded pipelines [8]. As part of this assessment, the main focus is placed on the following interrelated issues:

• Growth of corrosion defects.
• Verification of burst strength (allowable vs. maximum internal operating pressure).
• Verification of bending capacity (allowable and maximum external pressure, bending moment, and axial load).
• Assessment of the adequacy of remaining corrosion allowance for the expected service life.
• Inspection of corrosion defects.
• Updated inspection and maintenance programs [4].

When CO_2 and H_2S are present in the hydrocarbon fluid, two types of corrosion may occur: acid corrosion and low-sulfur corrosion [7]. CO_2 corrosion occurs in systems containing only carbon dioxide or trace amounts of hydrogen sulfide (partial pressure of $H_2S < 0.05$ psi). Acid corrosion occurs in systems containing hydrogen sulfide above a partial pressure of 0.05 psi (0.34 kPa) along with carbon dioxide. When corrosion products do not precipitate on the steel surface, extremely high corrosion rates several millimeters per year may occur [10]. This "worst-case" type of corrosion is the easiest to study and reproduce in laboratory conditions.

When CO_2 dominates the corrosion activity, the corrosion rate can be significantly reduced under conditions where iron carbonate can precipitate on the steel surface and form a dense, protective corrosion-product film. This occurs more readily at higher temperatures or higher pH values in the aqueous phase. When H_2S is present in addition to CO_2, iron sulfide films form instead of iron carbonate, and protective films may develop at lower temperatures, since iron sulfide precipitates much more easily than iron carbonate. Localized corrosion with very high corrosion rates may occur when the corrosion-product film does not provide sufficient protection, making this the most dangerous type of corrosion in oil and gas pipelines.

Carbon dioxide consists of one carbon atom and two oxygen atoms. It is a corrosive compound found in natural gas, crude oil, condensate, and formation water. It is one of the most common environments in the oilfield industry where corrosion occurs. CO_2 corrosion is intensified in the presence of both oxygen and organic acids, which can dissolve iron carbonate scale and prevent further scale formation. Carbon dioxide is a weak acid gas and becomes corrosive when dissolved in water. However, CO_2 must first hydrate to form carbonic acid (H_2CO_3) a relatively slow process before it becomes acidic. Carbonic acid lowers the pH of the water and causes corrosion upon contact with steel.

Areas where CO_2 corrosion is most prevalent include producing wells, gas-condensate wells, regions where water condensation occurs, CO_2-filled vessels, CO_2-saturated formation water, and pipelines, which generally corrode more slowly due to lower temperatures and pressures [6]. CO_2 corrosion is intensified in the presence of oxygen and organic acids, which dissolve iron carbonate scale and inhibit scale re-formation. The maximum solubility of CO_2 in water is 800 ppm. When CO_2 is present, the most common forms of corrosion include uniform corrosion, pitting, wormhole attack, galvanic mesa-corrosion, thermal corrosion, mesa attack, droplet corrosion, erosion-corrosion, and corrosion fatigue. The presence of CO_2 usually indicates the absence of hydrogen embrittlement. The corrosion rate in CO_2 environments is higher than that caused by carbonic acid alone. Corrosion rates in CO_2 systems can reach extremely high levels (several millimeters per year), but can be effectively inhibited.

Flow effects are very important in CO_2 systems. Turbulence is often a critical factor driving the system into a corrosive regime because it either prevents the formation of, or removes, the protective iron carbonate (siderite) scale. CO_2 corrosion products include iron carbonate (siderite, $FeCO_3$), iron oxide, and magnetite. The colors of corrosion products may appear green, brown, or black. Under certain conditions, these products may form protective layers. The scale itself can be soluble. Conditions that promote the formation of protective scale include elevated temperatures, increased pH as occurs in bicarbonate-containing waters and the absence of turbulence, allowing the scale film to remain intact. Turbulence is often a critical factor in the formation or retention of the protective iron carbonate film [5].

Iron carbonate is nonconductive; therefore, galvanic corrosion cannot occur. Corrosion develops only where the protective iron carbonate film is absent and is relatively uniform across the exposed metal surface. Crevice and pitting corrosion occur in the presence of carbonic acid. Carbon dioxide can also cause embrittlement, leading to stress corrosion cracking.

MATERIAL AND METHODS

1. The amines used in the synthesis of the corrosion inhibitors were obtained from Sigma-Aldrich.); the spectrum is shown in Figure 1-4
2. . The freezing point of the 10% solutions of the synthesized amine complexes in 70% IPA was determined according to GOST 20287-74, the relative density according to GOST 3900-2000, and the refractive index using an IRF-22 No. 700060 refractometer in accordance with GOST 18995.2-73.
3. The experiments were carried out using a "CorrTest" electrochemical potentiostat in a 1% sodium chloride (NaCl) solution saturated with CO2 at a pressure of 0.9 bar, a temperature of 50°C, and a duration of 1 hour. During the study, the main electrochemical parameters corrosion potential (Ecorr), current density (Icorr), and protection efficiency (η) obtained at different inhibitor concentrations were used to determine the adsorption behavior of the complexes on the metal surface and to elucidate their corrosion inhibition mechanisms. Electrochemical studies were conducted to investigate the corrosion-inhibiting efficiency of amino complexes (butylamine, octylamine diethylamine and dibutylamine) synthesized from the first fraction of natural petroleum acids (NPA) using the Tafel polarization method (Fig. 5-8).

Experimental Part

During the research conducted at the Institute of Petrochemical Processes named after Academician Y.H. Mammadaliyev (IPCP), four fractions (I, II, III, and IV) of natural petroleum acids (NPA) were isolated from the kerosene fraction obtained from a mixture of Baku crude oils, and alkyl and dialkylamine complexes were synthesized based on Fraction I. The following primary amines were used for the synthesis of the complexes: butylamine ($C_4H_9NH_2$), octylamine ($C_8H_{17}NH_2$), diethylamine ($(C_2H_5)_2NH$), and dibutylamine ($(C_4H_9)_2NH$).

The synthesis of the complexes was carried out as follows:

Natural petroleum acids and the alkyl or dialkylamines were taken in a 1:1 molar ratio and intensively stirred for 20–25 minutes, resulting in the formation of organic complexes. External heating was not required during the reaction, as it is an exothermic process accompanied by the release of a significant amount of energy. The resulting complexes are yellowish liquids with yields of 99.1–99.8%. The general schemes of the synthesis of NPA alkyl and dialkylamine complexes in a 1:1 molar ratio are presented below (Scheme 1 and Scheme 2).

$$RCOOH + R'NH_2 \longrightarrow RCO\overset{-}{O}\overset{+}{N}H_3R' \quad (1)$$

Where: R = residue of natural petroleum acid, R' = C_4H_9, C_8H_{17}

$$RCOOH + (R')_2NH \longrightarrow RCO\overset{-}{O}\overset{+}{N}H_2(R')_2 \quad (2)$$

Where: R = residue of natural petroleum acid, R' = $(C_2H_5)_2$, $(C_4H_9)_2$

The physicochemical properties of the solutions of the reagents obtained from Fraction I of natural petroleum acid are presented in Table 1.

Table 1. Physicochemical properties of 10% solutions of amine complexes of Fraction I of NPA in 70% IPA

Names of indicators:	N-1	N-2	N-3	N-4
Density (g/cm³)	0.8862	0.8833	0.8913	0,8908
Refractive index (at 20°C)	1.3803	1.3811	1.3813	1,3809
Freezing point, °C	-38	-44	-48	-40

The graphical representations of the IR spectra of the alkyl- and dialkylamine complexes of NPA are presented in Figures 1–4.

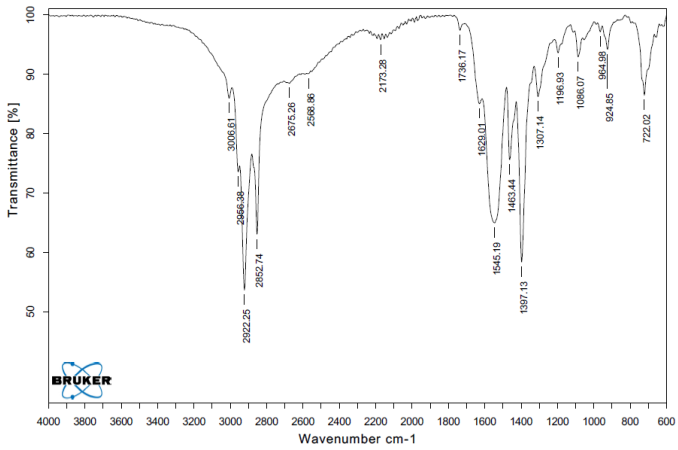

Fig. 1. Graphical representation of the IR spectrum of the butylamine complex of Fraction I of NPA

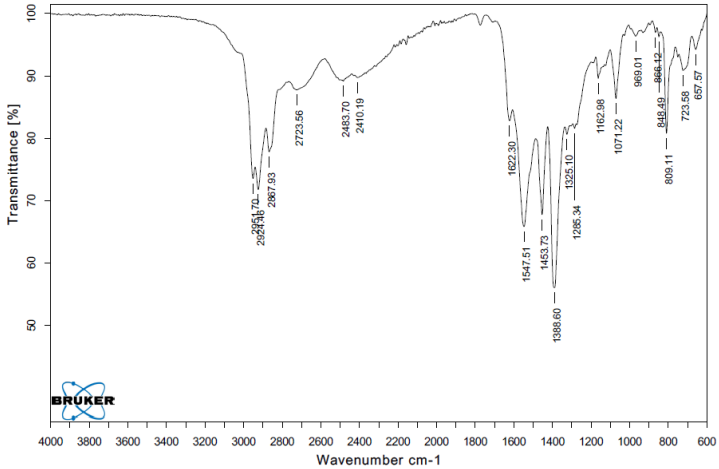

Fig.2 Graphical representation of the IR spectrum of the octylamine complex of Fraction I of NPA

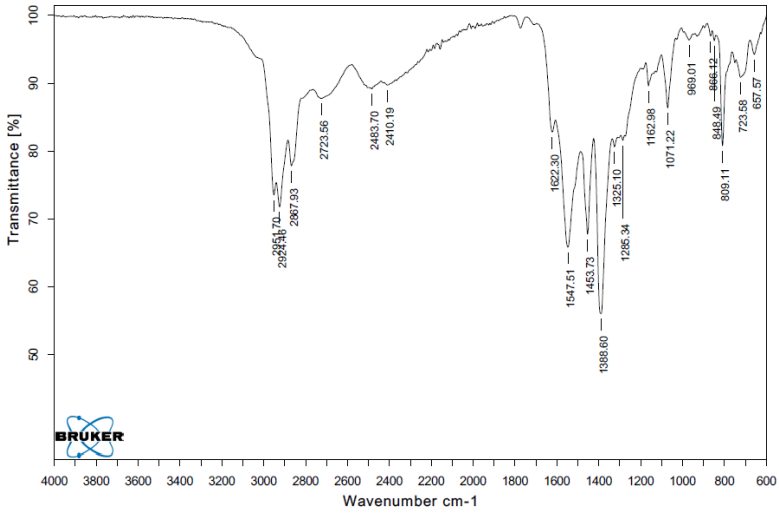

Fig.3. Graphical representation of the IR spectrum of the diethylamine complex of Fraction I of NPA

The structures of the obtained complexes were investigated using IR spectroscopy.

In the IR spectrum of the butylamine complex (N-1) of Fraction I of natural petroleum acid, the deformation and stretching vibrations of the C–H bonds of CH_3 and CH_2 groups were observed at 722, 1453, 2870, 2922, and 2956 cm^{-1}; the deformation vibration of the N–H bond at 1629 cm^{-1}; the stretching vibrations of the COO^- group at

1307, 1397, and 1549 cm^{-1}; and the stretching vibration of the NH^+ group (ammonium band) at 2414, 2477, and 2584 cm^{-1}.

In the IR spectrum of the octylamine complex (N-2) of Fraction I of natural petroleum acid, the deformation and stretching vibrations of the C–H bonds of CH_3 and CH_2 groups were detected at 723, 1453, 2867, 2924, and 2951 cm^{-1}; the deformation vibration of the N–H bond at 1622 cm^{-1}; the stretching vibrations of the COO^- group at 1388 and 1547 cm^{-1}; and the stretching vibrations of the NH^+ group (ammonium band) at 2483 and 2723 cm^{-1}.

In the IR spectra of the diethylamine and dibutylamine complexes (N-3 and N-4) of Fraction I of natural petroleum acid, the deformation and stretching vibrations of the C–H bonds of CH_3 and CH_2 groups appeared at 723, 1453, 2867, 2924, and 2951 cm^{-1}; the deformation vibration of the N–H bond at 1622 cm^{-1}; the stretching vibrations of the COO^- group at 1325, 1388, and 1547 cm^{-1}; and the stretching vibrations of the NH^+ group (ammonium band) at 2410, 2483, and 2723 cm^{-1}.

Discussion of the Results Obtained

The results obtained from studying the effect of 10% solutions of the amine complexes derived from Fraction I of natural petroleum acid in 70% IPA on the corrosion process in a carbon dioxide environment by the Tafel method are presented in Table 2.

Table 2. Results obtained from the Tafel method study of the effect of amine complexes derived from Fraction I of NPA on the corrosion process

Name of substances	Concentration, ppm	E_{cor} mV	$İ_{corr}$ A/sm²	Corrosion rate, mm/year	Protection efficiency, %
Without inhibitor	–	-731	5.7576×10^{-5}	0.675	–
N-1 (butylamine complex)	500	-730	5.3056×10^{-6}	0.062	90.7
	1000	-670	5.763×10^{-7}	0.006	98.8
N-2 (octylamine complex)	500	-748	1.8098×10^{-5}	0.212	67.7
	1000	-742	8.8093×10^{-6}	0.103	84.9
N-3 (diethylamine complex)	500	-755	3.5405×10^{-5}	0.415	40.0
	1000	-731	4.2819×10^{-6}	0.050	92.5
N-4 (dibutylamine complex)	500	-745	1.4139×10^{-5}	0.165	75.8
	1000	-747	1.4545×10^{-5}	0.170	75.3

As seen from table 2, in the control sample without inhibitor (blank test), the corrosion current density was 5.7576×10^{-5} A/cm², and the corrosion rate was 0.675 mm/year. These values indicate that the medium exhibits an aggressive character toward carbon steel. When the inhibitor was added to the medium, the results changed as follows:

N-1 (NPA + Butylamine complex)-At a concentration of 1000 ppm, this complex reduced Icorr to 5.763×10^{-7} A/cm², and the corrosion rate decreased to 0.006 mm/year. This corresponds to a protection efficiency of 98.8%. This effect is attributed to the electron-donating role of the primary amine group in the structure of butylamine and its strong adsorption onto the metal surface when forming a complex with NPA. Additionally, the shift of Ecorr from –731 mV to –670 mV indicates the suppression of anodic processes.

N-2 (NPA + Octylamine complex)-The long alkyl chain of octylamine increases the hydrophobicity of the complex, limiting the transport of corrosive ions to the metal surface. At 1000 ppm, this complex exhibited a protection efficiency of 84.9%. However, the solubility and adsorption characteristics of long-chain amines create certain difficulties in achieving dense molecular packing on the metal surface.

N-3 (NPA + Diethylamine complex)-At 500 ppm, the protection efficiency was only 40%, but at 1000 ppm, it increased sharply to 92.5%. This demonstrates that the inhibitor's efficiency strongly depends on its concentration. It should be noted that the two alkyl chains of the diethylamine molecule may somewhat weaken adsorption onto the metal surface; however, as the concentration increases, a denser and more stable protective layer forms on the surface.

N-4 (NPA + Dibutylamine complex)-The protection efficiency of this complex ranged between 75–76%. Although the presence of two butyl groups enhances its spreading ability on the surface, conformational limitations affecting molecular arrangement weaken adsorption, resulting in lower protection efficiency.

The graphical representations of the Tafel curves for the inhibitors are presented below (Fig. 5–8).

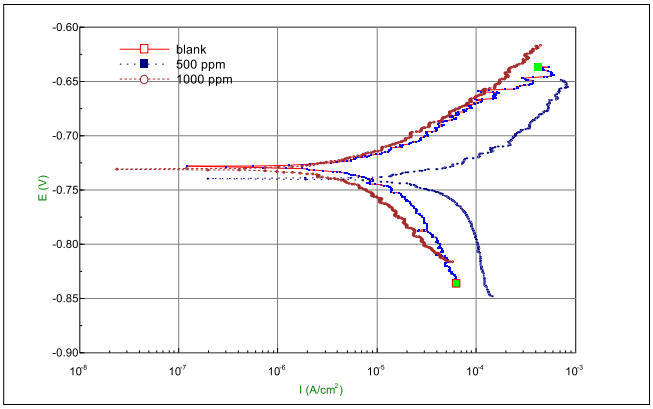

Fig. 4. Tafel polarization curves of the 10% solution of the butylamine complex (N-1) of Fraction I of NPA in 70% IPA.

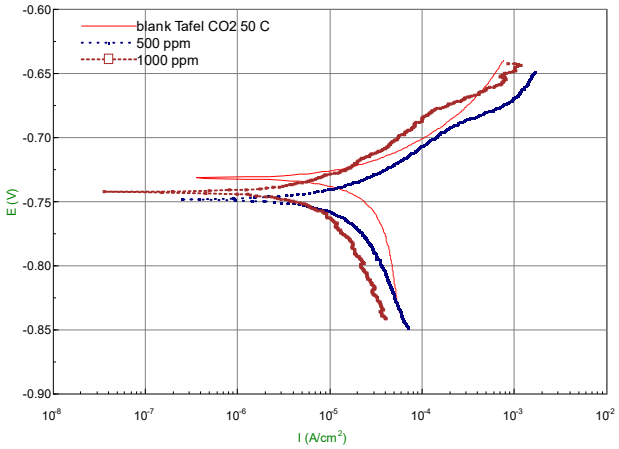

Fig. 5. Tafel polarization curves of the 10% solution of the octylamine complex (N-2) of Fraction I of NPA in 70% IPA.

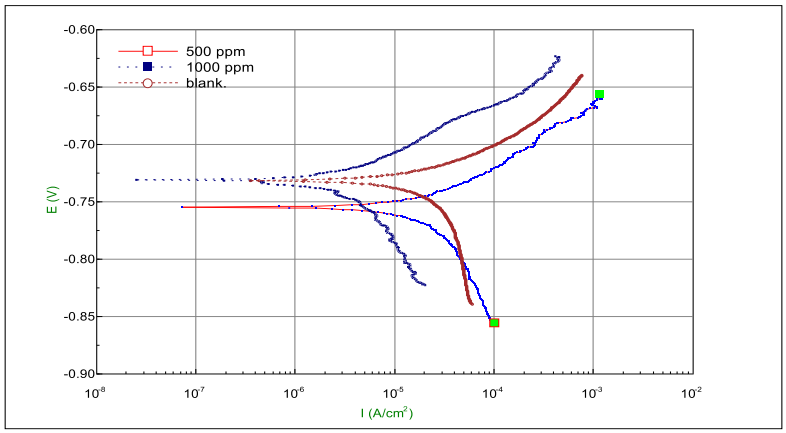

Fig. 6. Tafel polarization curves of the 10% solution of the diethylamine complex (N-3) of Fraction I of NPAin 70% IPA

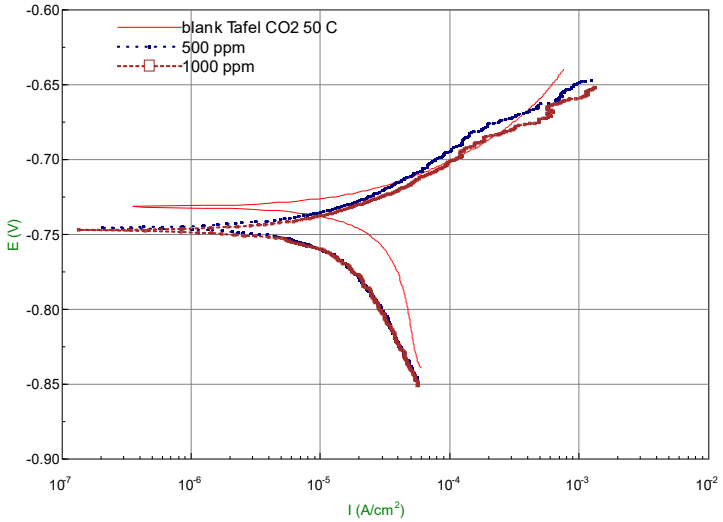

Fig. 7. Tafel polarization curves of the 10% solution of the dibutylamine complex (N-4) of Fraction I of NPA in 70% IPA.

RESULTS

Thus, the obtained results show that the amine complexes (especially butylamine and diethylamine) can significantly reduce the corrosion process when applied at high concentrations. The data obtained from the Tafel curves indicate that these substances decrease the rate of metal degradation by suppressing both anodic and cathodic reactions, demonstrating their high efficiency as corrosion inhibitors.

The simple synthesis procedure of these complexes, their derivation from natural raw materials, and their environmental safety make them suitable for industrial-scale application.

Abstract

Postural deviations from the physiological spinal curves are common, especially among individuals who remain in static positions for extended periods, as is often the case with students. In this context, students at "Aldent" University, due to the nature of their studies in the field of medicine, represent a high-risk group for developing such issues as a result of repetitive positions and prolonged sitting during theoretical lessons or clinical practice.
The aim of this study is to assess students of Aldent University regarding potential spinal problems in the sagittal plane, raise awareness on the importance of correct posture, and promote postural education, counseling, and physiotherapeutic treatment.
The study was conducted over a one-month period and included 300 students aged 19–25. All participants shared the common characteristic of sitting for more than 5 hours per day and maintaining forced postures during most of the day.
The data were statistically processed by analyzing gender, employment status, spinal deviations, the presence of pain, and the spinal regions affected.
Results showed that 63% of students had postural deviations; of these, 52.9% were female and 47.1% male. Based on gender and spinal region, the findings were as follows:
- Cervical hyperlordosis: 7% of females and 3.37% of males
- Cervical hypolordosis: 25% of females and 17.97% of males
- Thoracic hyperkyphosis: 39% of females and 6.74% of males
- Lumbar hyperlordosis with increased pelvic anteversion: 27% of females and 2.24% of males
- Lumbar hypolordosis with pelvic retroversion: 18% of females and 29.21% of males

Keywords: Spine, postural deviation, assessment, sagittal plane, physiotherapy

INTRODUCTION

The assessment of the spinal column in the sagittal plane among students of Aldent University holds particular importance, as it is closely related to their daily activities, the positions they maintain during studies, and their professional obligations in the medical field.
Postural deviations in this plane are associated with alterations in the physiological curves of the spine, such as kyphosis, lordosis, pelvic anteversion, and retroversion.
Physiotherapy plays a fundamental role in the assessment, education, counseling, and treatment of these issues, helping to correct deviations and alleviate pain that may arise within this age group.

MATERIALS AND METHODS

The study was conducted with students of Aldent University over a one-month period, in December 2024. A total of 300 students aged 19–25 years were included. All participants shared the common characteristic of sitting for more than 5 hours per day and maintaining a static, forced posture for a significant part of the day.
The data were processed statistically by analyzing variables such as gender, employment status, spinal deviations, presence of pain, and the regions where these deviations appeared.

RESULTS

Table 1: Incidence of employed and unemployed participants

	Number of participants	Percentage
Employed	216	72%
Unemployed	84	28%

Table 2: Incidence of employed in the profession and outside the profession

	Number of participants	Percentage
Employement in the profession	38	17.59%
Employement outside the profession	178	82.4%

Table 3: Participants by gender

	Number of participants	Percentage
Male	150	50%
Female	150	50%

Table 4: Participants who tested positive for spinal deviations

	Number of participants	Percentage
Spinal deviations	189	63%
No spinal deviations	111	37%

Table 5: Participants who tested positive for spinal deviations according to gender

	Number of participants	Percentage
Female	100	52.9%
Male	89	47.08%

Table 6: Regions of the spine that tested positive for spinal deviations

		Number of participants	Percentage
Female	Cervical Hyperlordosis	7	7%
	Cervical Hypolordosis	25	25%
	Thoracic Hyperkyphosis	39	39%
	Thoracic Hypokyphosis	0	0%
	Lumbar Hyperlordosis	27	27%
	Lumbar Hypolordosis	18	18%
	Increased pelvic anteversion	27	27%
	Pelvic retroversion	18	18%

	Cervical Hypolordosis	16	17.97%
	Thoracic Hyperlordosis	6	6.74%
	Thoracic Hypokyphosis	0	0%
	Lumbar Hyperlordosis	2	2.24%
	Lumbar Hypolordosis	26	29.21%
	Increased pelvic anteversion	2	2.24%
	Pelvic retroversion	26	29.21%

Chart 1: Incidence of Spinal Problems in the Sagittal Plane

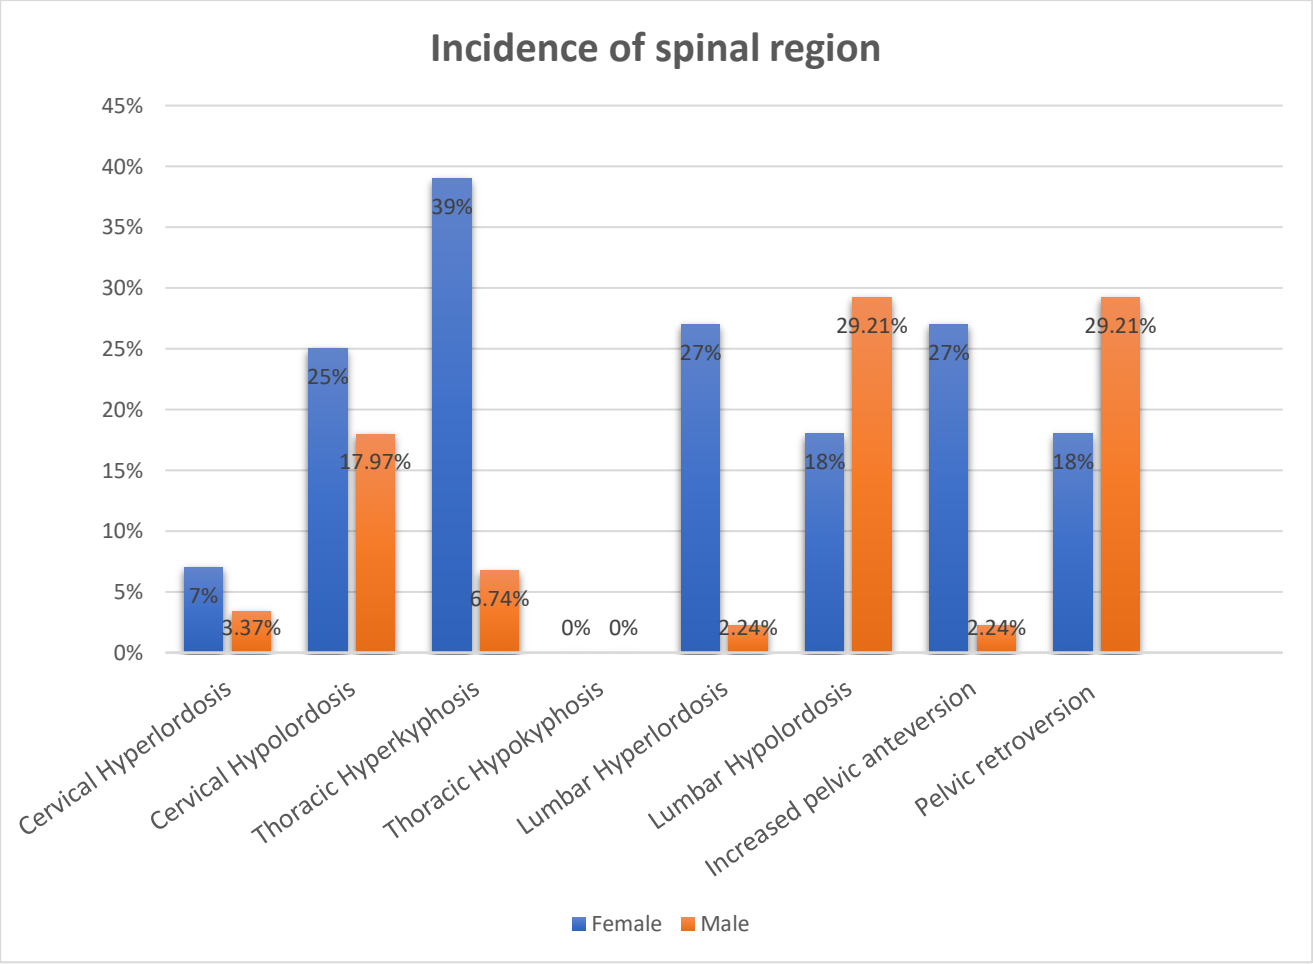

Table 7: Participants with pain and without pain

	Number of participants	Percentage
With pain	163	86.24%
Without pain	26	13.75%

CONCLUSIONS

Postural deviations are common, especially among the student population. Out of 300 evaluated students, 63% showed spinal deviations.

Postural deviations are associated with several factors; among the 300 assessed students, 72% were employed, of whom 17.59% were working in their professional field.

Gender was equally represented, with 50% females and 50% males. Among those with postural deviations (63%), 52.9% were female and 47.08% male. Postural deviations, based on gender and spinal regions, showed the following:

- 7% of females and 3.37% of males had cervical hyperlordosis
- 25% of females and 17.97% of males had cervical hypolordosis
- 39% of females and 6.74% of males had thoracic hyperkyphosis
- 27% of females and 2.24% of males had lumbar hyperlordosis and increased pelvic anteversion
- 18% of females and 29.21% of males had lumbar hypolordosis and pelvic retroversion

Abstract

Activation of the deep stabilizing trunk muscles, such as the Multifidus and Transversus Abdominis (TrA), is essential for maintaining lumbopelvic stability and reducing lower back pain. Proprioceptive Neuromuscular Facilitation (PNF) protocols are known for their effectiveness in enhancing neuromuscular control and postural strength.
The aim of this study is to evaluate the impact of a PNF-based exercise protocol on increasing the activation of the Multifidus and Transversus Abdominis muscles, using physiotherapeutic functional tests as assessment tools.
The study included 10 participants (aged 20–25) presenting with mild symptoms of lumbar instability. Over a 4-week period, they underwent a PNF exercise program focused on trunk stabilization. Muscle activation was assessed before and after the intervention using dynamic functional tests:
- Prone Instability Test
- Active Straight Leg Raise (ASLR)
- Trunk Flexion Control Test
Post-intervention results showed improvements in all participants, with better performance in the functional tests, increased stability, and improved movement control. Participants also reported a noticeable reduction in fatigue and discomfort in the lumbar region.
PNF exercises have a positive impact on enhancing the function and control of the Multifidus and Transversus Abdominis muscles. Functional physiotherapeutic testing proved to be a practical and effective method for evaluating changes in muscle activation.

Keywords: PNF, Multifidus, Transversus Abdominis, muscle activation, lumbar stability

INTRODUCTION

The stability of the vertebral column plays a crucial role in preventing and managing lower back pain. Two of the most important muscles contributing to this function are the Multifidus and Transversus Abdominis, which are considered key muscles for segmental trunk stabilization. Poor activation of these muscles is often associated with muscular imbalances and an increased incidence of injuries in the lumbar region.

One therapeutic approach that has gained attention in the field of physiotherapy is Proprioceptive Neuromuscular Facilitation (PNF). This method aims to enhance neuromuscular control, strength, and flexibility through functional movement patterns that stimulate the nervous and muscular systems in an integrated way.

This case study aims to assess the impact of a treatment protocol using PNF techniques on improving the functional activation of the Multifidus and Transversus Abdominis muscles, through dynamic physiotherapeutic assessment tests, in individuals with reduced trunk stability. The findings of this study may contribute to the improvement of clinical treatment and rehabilitation practices in musculoskeletal disorders affecting the lumbar area.

MATERIALS AND METHODS

This is a case study conducted with 10 students from Aldent University (ages 20–25), including 5 females and 5 males. The participants presented signs of reduced trunk stability and reported low back pain. Inclusion criteria required that participants had no significant associated muscular or neurological pathologies. All participants provided informed consent prior to their involvement in the study.

Each participant underwent a 4-week PNF exercise protocol, with sessions held three times per week. The protocol included diagonal trunk and pelvic movement patterns, progressive resistance exercises, and the rhythmic stabilization technique.

Data were processed statistically by evaluating muscle tone and pain levels before and after the application of PNF techniques. The aim was to assess the effect of PNF in improving the functional activation of the Multifidus and Transversus Abdominis muscles.

RESULTS

Table 1: Pain intensity before and after the application of PNF

	VAS before PNF	VAS after PNF
The patient 1	7	3
The patient 2	6	2

The patient 7	3	5	3	5
The patient 8	1	3	1	4
The patient 9	4	5	3	5
The patient 10	3	4	2	4

Note: 0-no muscle activation, 1-very weak activation, 2- weak activation, 3-moderate activation, 4-good activation, 5-optimal activation.

Table 6: Dynamic assessment of patients through the Trunk Flexion Control test

	Multifidus muscles		Transversus abdomini muscle	
	Muscle tone before PNF	**Muscle tone after PNF**	**Muscle tone before PNF**	**Muscle tone after PNF**
The patient 1	1	4	1	33
The patient 2	3	5	2	4
The patient 3	1	3	1	3
The patient 4	4	5	3	5
The patient 5	1	2	3	4
The patient 6	2	4	2	3
The patient 7	3	5	3	5
The patient 8	1	3	1	4
The patient 9	4	5	3	5
The patient 10	3	4	2	4

Note: 0-no muscle activation, 1-very weak activation, 2- weak activation, 3-moderate activation, 4-good activation, 5-optimal activation.

CONCLUSIONS

Following the application of PNF protocols, a noticeable improvement was observed in the activation of the Multifidus and Transversus Abdominis muscles in all 10 participants. Dynamic assessments through the Prone Instability Test, Active Straight Leg Raise, and Trunk Flexion Control Test showed increased muscle tone and functionality, reflected in the improvement of numerical scores from pre- to post-treatment.

These improvements are significant for enhancing lumbar stability and reducing pain symptoms, thereby increasing functional capacity and overall quality of life. The results support the effectiveness of PNF protocols as a physiotherapeutic method for activating the core stabilizing muscles of the spine and abdomen.

However, the small sample size highlights the need for larger and more comprehensive studies to confirm these findings and to determine the optimal parameters for treatment.

It is recommended that PNF techniques be implemented regularly and periodically for the maintenance of lumbar stability, with individualized adaptation of protocols according to each patient's specific needs.

ORAL PRESENTATION

Maternal and Infant Outcomes of Breastfeeding and Formula Feeding: A Quantitative Comparative Study

Mirva Hoxha (ORCID: https://orcid.org/0009-0004-2757-3340)

Aldent University, Faculty of Medical Tecnical Sciences, Department of Nursing, Tirana, Albania.

Abstract

Infant feeding during the first months of life plays a crucial role in healthy growth and directly influences the physical and emotional well-being of both the newborn and the mother. This study aims to explore and compare the impact of two common feeding methods—breastfeeding and formula feeding—on both maternal and infant outcomes (Krol et al., 2018; Sánchez-Vincitore et al., 2024). A quantitative approach was applied using an anonymous questionnaire distributed to mothers with diverse infant feeding experiences. The survey assessed variables such as type of feeding in the first six months, duration of breastfeeding, maternal emotional responses, feeding-related challenges, social support, and mothers' perceptions of infant health and bonding (Can et al., 2025; Chambers et al., 2023). Results showed that breastfeeding was strongly associated with positive effects on infant emotional development, reduced digestive problems, and enhanced bonding with the mother (Krol et al., 2018). Breastfeeding mothers reported greater emotional fulfillment, fewer feelings of guilt, and additional physical benefits such as postpartum recovery and weight loss, although some experienced difficulties including nipple pain and fatigue (Rowles et al., 2025; Wheeler et al., 2024). Conversely, formula feeding was valued for its practical convenience but was more often linked to infant digestive discomfort and maternal insecurity, especially when it was not the first-choice method (Fallon et al., 2016). Across both groups, the level of social and partner support emerged as a decisive factor shaping the maternal emotional experience (Tessema et al., 2025). This study emphasizes the importance of structured healthcare and educational interventions to guide and support mothers in their feeding choices. Promoting awareness of breastfeeding benefits, providing assistance in overcoming lactation challenges, and ensuring non-judgmental acceptance of different approaches are essential for fostering a healthier and more supportive environment for mothers and infants (Hussain et al., 2025).

Keywords*:* breastfeeding, formula feeding, infant health, maternal well-being, nursing role

INTRODUCTION

Infant feeding during the first months of life is a fundamental determinant of health and well-being, influencing both immediate and long-term outcomes for the child as well as the mother (Krol et al., 2018). Nutrition in early infancy shapes the immune system, supports growth, and fosters neurological development while affecting emotional security and the quality of the mother–infant bond (Sánchez-Vincitore et al., 2024). Among the most common methods of infant feeding are breastfeeding and formula feeding, each associated with distinct benefits and challenges (Fallon et al., 2016).

The primary aim of this study is to analyze and compare the effects of breastfeeding and formula feeding on the physical and emotional health of infants during the early stages of life. In addition to evaluating physiological outcomes, the study seeks to explore the emotional impact of these feeding practices on both infants and mothers (Can et al., 2025). By adopting a multidimensional perspective, the research addresses biological, psychological, and social aspects of feeding choices.

Breastfeeding is recognized for its protective role in infant immunity, optimal growth, and maternal bonding, mediated by hormones such as oxytocin and prolactin (Krol et al., 2018). Conversely, formula feeding may provide practical advantages but can be associated with digestive issues and maternal stress or guilt when not the preferred option (Fallon et al., 2016; Wheeler et al., 2024). Parental decisions are also shaped by social, economic, and cultural factors, making evidence-based guidance essential for healthcare professionals, parents, and policymakers (Chambers et al., 2023; Tessema et al., 2025).

MATERIALS AND METHODS:

Literature Review

A systematic review of peer-reviewed articles, WHO reports, and national health documents was conducted to establish the theoretical framework of the study (Hussain et al., 2025). The review focused on breastfeeding and formula feeding and their effects on maternal and infant physical and emotional health (Krol et al., 2018; Fallon et al., 2016).

Quantitative Study

A descriptive quantitative design was employed using a structured anonymous questionnaire distributed to mothers with diverse feeding experiences. The questionnaire collected data on feeding type, breastfeeding duration, maternal emotional responses, feeding difficulties, perceived infant health and bonding, and social/partner support (Can et al., 2025; Chambers et al., 2023). Responses were analyzed using descriptive statistics and presented via tables, and summaries.

RESULTS

Table 1: Dermografic datas

	Age group	Marital status	Number of children	Education
<20	5			
21-30	70			
31-40	25			
Married		78		
Divorced		13		
Cohabiting		9		
1 child			50	
2 children			35	
3 or more			15	
University				60
Secondary				30
Primary				10

This section presents the demographic data of the mothers who participated in the study.

The majority of respondents belong to the age group 21–30 years, while other groups such as those aged 31–40 years and under 20 years are represented in smaller proportions.

2, 78% of mothers are married, making up the overwhelming majority of participants. 13% are divorced, while 9% live in cohabitation without formal marriage. These data are significant in understanding the social and emotional context of the mother–child relationship within this study.

A considerable proportion of mothers have one child, while another large share have two children. Mothers with more than three children make up a smaller, but important percentage for analysis, since emotional and physical demands vary according to the number of children.

Most of mothers have completed university education, followed by those with secondary education. A smaller proportion have only 9-year education, but they are included to provide a full overview of the participants' educational levels.

Table 2: Infant Feeding Practices, Physical and Emotional Experiences, Social and Emotional Support and Infant Health and Future Feeding Intentions

	Feeding method (0-6 months)	Breastfeeding duration	Reasons for not breastfeeding	Breastfeeding experience	Emotional bonding
Exclusive breastfeeding	47				
Breast+formula	53				
<1 month		6			
1-3 months		16			
4-6 months		25			
>6 months		53			
Insufficient milk			19		
Personal choice			19		
Infant refusal			10		
Medical problems			3		
Other reasons			49		
Very easy				34	
Easy				53	
Difficult				10	
Very difficult				3	
Very strong					97
Moderate					3

This section presents data on how mothers fed their infants during the first six months of life, 53% of mothers chose a combination of breastfeeding and formula, while 47% exclusively breastfed during the first six months.
Most of mothers breastfed their infants for more than six months. A small minority (6%) breastfed for less than one month, while 25% breastfed for 4–6 months and 16% for 1–3 months. This distribution reflects a variety of practices influenced by factors such as maternal/infant health, social pressure, work demands, and family support.
49% of mothers reported other reasons for not breastfeeding beyond the main categories provided in the questionnaire. These may include stress, lack of support, or particular family/economic circumstances. The most common specific reasons were insufficient milk production (19%) and personal choice (19%), indicating that the decision not to breastfeed often extends beyond health factors. 10% reported infant refusal, and only 3% cited health problems.
The majority of mothers found breastfeeding to be a positive experience, describing it as easy (53%) or very easy (34%). However, 10% considered it difficult and 3% very difficult, highlighting challenges such as pain, stress, or insufficient support.
44% of mothers reported no physical discomfort during breastfeeding, which is a positive indicator of their experience. Nonetheless, 34% experienced discomfort rarely, 16% occasionally, and 6% frequently, emphasizing the need for medical and psychological support in some cases.
55% did not experience any of the listed breastfeeding-related issues. However: 26% reported physical fatigue, likely due to frequent feeding or lack of practical support. 10% experienced nipple cracking. 9% reported breast pain or mastitis, a condition requiring medical attention.
Breastfeeding had varying effects on maternal weight: 44% reported no change, maintaining balance in metabolism and daily activity. 44% reported weight loss, consistent with studies suggesting breastfeeding aids postpartum weight reduction. 12% reported weight gain, possibly due to stress, unbalanced diet, or limited physical activity. The majority perceived breastfeeding as very positive (69%) or positive (22%), describing it as emotionally fulfilling. A small proportion reported neutral (6%) or negative experiences (3%), often linked to

physical difficulties or lack of support. 13, 97% of mothers felt strongly emotionally connected to their infant while breastfeeding. Only 3% reported feeling somewhat connected, suggesting a generally strong emotional bond in this process. 72% did not experience feelings of guilt about how they fed their infant, reflecting confidence and adequate support. However, 28% did report feelings of guilt, likely linked to social pressures, comparisons, or inability to breastfeed as desired. 84% of mothers felt strongly supported by their partner and family in their feeding choice, showing the importance of a positive support system. 16% felt little support, which may negatively affect emotional well-being.

59% reported no digestive problems in their infants. Among the remainder, 38% noted digestive issues during formula feeding, while only 3% reported such problems during breastfeeding. The majority (72%) would choose exclusive breastfeeding if they had another child, indicating strong trust in its nutritional and emotional benefits. 19% remain undecided, while 9% would choose a combination of breastfeeding and formula.

DISCUSSION

The findings of this study provide valuable insights into maternal and infant experiences related to breastfeeding and formula feeding, highlighting both the benefits and challenges of each method.

Breastfeeding was associated with emotional and physical benefits for both mother and infant (Krol et al., 2018; Rowles et al., 2025). Formula feeding provided a safe alternative but was more often linked to maternal guilt and infant digestive discomfort (Fallon et al., 2016; Wheeler et al., 2024). Social support from partners, family, and healthcare professionals significantly influenced maternal confidence and satisfaction (Can et al., 2025; Chambers et al., 2023; Tessema et al., 2025).

Practical Implications

Strengthen pre- and postnatal education programs (Hussain et al., 2025).

Expand access to lactation support.

Implement workplace policies supporting breastfeeding.

Normalize safe feeding choices without stigma.

Limitations and Future Research

While the study provides meaningful insights, limitations include the relatively small sample size and the specific socio-cultural context, which may limit generalizability. Future research should examine larger, more diverse populations and investigate long-term outcomes of different feeding practices on child development and maternal well-being. Additionally, qualitative approaches could further illuminate personal experiences, challenges, and decision-making processes surrounding infant feeding.

CONCLUSIONS AND RECOMMENDATIONS

Based on the literature review and analysis of data collected through a structured questionnaire, this study has drawn several significant conclusions regarding the impact of breastfeeding and formula feeding on the physical and emotional well-being of infants and mothers:

Breastfeeding as the Optimal Feeding Method: Breastfeeding is recognized as the most beneficial form of infant feeding, not only for its nutritional and disease-protective benefits but also for fostering a strong emotional bond between mother and child.

This form of feeding has been associated with reduced stress and anxiety levels in mothers, as well as positive emotional regulation in infants.

Formula Feeding and Maternal Emotions: While formula feeding serves as a necessary alternative in certain situations, it has been linked to higher levels of insecurity and, at times, guilt among mothers.

However, in circumstances where breastfeeding is not feasible, formula feeding provides a viable option to ensure the infant's health by offering a balanced nutritional profile.

Influence of Socioeconomic and Cultural Factors: Social, economic, and cultural factors play a crucial role in maternal feeding decisions. Support from healthcare professionals, access to reliable information, and the absence of social stigmas have been identified as key determinants in the positive breastfeeding experiences of mothers.

Statistical Analysis of Maternal and Infant Well-being: Quantitative data analysis revealed clear trends linking feeding methods to various aspects of physical and emotional well-being in both mothers and infants. These findings underscore the importance of providing adequate support to mothers during this critical period.

Recommendations

Healthcare systems should strengthen educational programs to provide mothers with balanced information on breastfeeding and formula feeding, while also expanding access to postpartum professional support such as lactation consultants. Supportive workplace policies, including flexible hours, breaks, and designated spaces, are essential to help mothers maintain healthy feeding practices after returning to work. Equally important is fostering a culture that normalizes and respects all feeding choices, reducing stigma and promoting informed decision-making. Finally, further research involving diverse populations is needed to guide effective interventions and policies that enhance maternal and infant health.

ORAL PRESENTATION

The role of biology in promoting education for sustainable development in upper secondary education

Sara Pupe

Department of Biology, Aldent University, Albania

Abstract

Biology education plays a crucial role in developing students' scientific knowledge and their ability to analyze and apply theoretical concepts in real-life contexts. A key aspect of this subject is the integration of practical work, which enables students to understand biological phenomena through direct experience. This study aims to examine the impact of practical activities on learning outcomes in biology, assessing how such methods support knowledge acquisition and the development of students' competencies.The study also explores the central role of biology education in promoting sustainable development at the secondary education level. Education for sustainability requires the cultivation of competencies such as systems thinking, forecasting, and solving complex problems. Biology, through modules such as evolution, biodiversity, ecology, and health, provides both theoretical and practical foundations for environmental awareness and sustainable development. Pedagogical strategies supporting these objectives include field trips, laboratory work, project-based learning, socio-scientific discussions, and the integration of scientific competencies.The research was conducted at the University of Tirana (Faculty of Natural Sciences), Aldent University, and five high schools (*Ismail Qemali*, *Sami Frashëri*, *Sinan Tafaj*, *18 Tetori*, and *Vath Korreshi*). A total of 180 biology teachers, 10 school leaders, 60 high school students, and 90 university students participated, using anonymized data from learning management systems.The findings provide recommendations for educational policy and curriculum development: promoting teacher training in education for sustainability, providing appropriate tools and resources for biology teaching, and scaling up the use of active and collaborative learning methods.

Keywords: education, teaching, sustainable development, competency development, learning outcomes

Study Aim: The primary aim of this study is to explore and evaluate the ways in which biology, as a scientific subject, contributes to the promotion of education for sustainable development (ESD) at the upper secondary education level. Specifically, the study seeks to:

Identify existing pedagogical practices that integrate sustainability concepts into biology instruction, such as fieldwork, ecological laboratories, and topics including biodiversity and ecosystem conservation;

Analyze the challenges and barriers encountered when incorporating sustainability into biology teaching, including limited teacher training, time constraints for extracurricular content, insufficient resources, and resistance to pedagogical change.

Methodology

This study employs a mixed-methods approach, combining quantitative and qualitative strategies. Quantitative data were collected through questionnaires administered to students and university learners, while qualitative insights were gathered through interviews with biology teachers. This integrated approach allows for a comprehensive understanding of both individual perceptions regarding sustainability factors and realistic pedagogical practices, thereby substantially enhancing the interpretability and validity of the findings.

Conclusion

The role of biology in promoting education for sustainable development (ESD) at the upper secondary education level is crucial for the scientific and professional formation of students. Integrating sustainability into biology education fosters greater awareness and encourages active engagement towards a more sustainable future. Achieving this requires close collaboration among teachers, students, and policymakers to enhance the quality and effectiveness of instruction in this field.

Keywords: education, teaching, sustainable development, competency development, learning outcomes

Introduction

One of the most important objectives of humanity in the 21st century is the construction of a sustainable society. Education plays a key role in achieving sustainability and is itself a cornerstone for building a sustainable society. In a period of rapid ecological and social transformation, education is crucial for shaping students who are engaged, responsible, and capable of addressing complex environmental and societal challenges.In this context, biology—as a discipline that studies life and its interactions with the environment—provides an exceptional opportunity to integrate the principles of sustainable development into upper secondary education. Through biology education, students can develop the knowledge and skills necessary to understand and respond to environmental and social challenges affecting everyday life. This integration aligns with the United Nations Sustainable Development Goals (SDGs), which aim to ensure that all learners acquire the knowledge and competencies required to promote sustainable development.This study aims to examine how biology education can contribute to education for sustainable development (ESD) in upper secondary schools. Using a mixed-methods approach, including questionnaires with students and university learners as well as interviews with biology teachers, the study analyzes perceptions, knowledge, and practices related to integrating sustainability themes into biology instruction. The research provides a clear overview of the effectiveness of biology teaching in promoting sustainable development and identifies opportunities to enhance this process within the context of upper secondary education.

The study was conducted at the University of Tirana (Faculty of Natural Sciences), Aldent University, and five high schools (*Ismail Qemali*, *Sami Frashëri*, *Sinan Tafaj*, *18 Tetori*, and *Vath Korreshi*). In total, 180 biology teachers, 10 school leaders, 60 high school students, and 90 university students participated, using anonymized data from learning management systems.

This research addresses several key questions:

What are the current pedagogical practices of biology teachers in integrating sustainable development concepts into their teaching?

What challenges do biology teachers face when attempting to incorporate sustainability concepts into their instructional practices?

What resources and support are provided to biology teachers and students for teaching sustainability concepts in the classroom, and what challenges are encountered in integrating these topics into the biology curriculum?

Literature Review

The concept of sustainable development was first introduced in the Brundtland Report by the World Commission on Environment and Development (Brundtland et al., 1987). Since then, it has become increasingly important in addressing the complex challenges faced by humanity in the 21st century. According to Filho et al. (2018), pursuing sustainable development has become vital due to growing concerns about environmental degradation, social inequality, and economic instability.Education plays a critical role in shaping beliefs, attitudes, and

behaviors toward sustainability. Hogan and O'Flaherty (2021) assert that education is a key tool for achieving the objectives of sustainable development. Within this context, biology education is particularly significant, given its focus on biodiversity, ecological systems, and the interdependence of all species on Earth.Active learning approaches, such as outdoor education and project-based learning, have been highlighted as effective methods for promoting sustainable development concepts in secondary education (Jeronen et al., 2016). These approaches help students develop critical thinking skills and adopt a systems perspective when addressing environmental and social issues. Empirical evidence from Sweden indicates that integrating sustainability-related topics into biology instruction enables students to gain a deeper understanding of the connections between human activities and their environmental impacts. Furthermore, Cebrián, Junyent, and Mulà (2021) emphasize that education across all levels and disciplines must be fundamentally reoriented to advance sustainable living, democracy, and human well-being. Incorporating sustainability into biology education not only fosters scientific literacy but also encourages active, responsible participation in addressing societal and environmental challenges.

Methodology

This study employs a mixed-methods approach, integrating both quantitative and qualitative strategies to collect and analyze data.

For students:

Questionnaires: Both closed- and open-ended questions were used to assess students' knowledge of environmental issues and sustainability concepts.

In-depth interviews: Conducted to explore students' perceptions of the importance of sustainable development and the role of biology in shaping these perceptions.

For teachers:

Questionnaires: Focused on teaching practices and the integration of sustainability-related topics into biology instruction.

Interviews: Conducted to examine teachers' experiences in delivering biology lessons and the challenges encountered in integrating sustainable development concepts.

Data Analysis:

Quantitative analysis: Statistical analyses were performed using SPSS to examine numerical data and identify correlations between students' environmental knowledge and their attitudes toward sustainability.

Qualitative analysis: Thematic coding was applied to interview responses to identify key themes regarding the impact of biology education on fostering sustainable development awareness and competencies.

This integrated methodological approach allows for a comprehensive understanding of both the pedagogical practices in biology education and the perceptions of students regarding sustainability, thereby enhancing the validity and depth of the study's findings.

Results and Discussion

Student Questionnaires:

Frequency of sustainability-related topics in biology: According to the survey, 21% of students reported that topics on the impact of human activities on the environment were covered, 37% indicated biodiversity and its conservation, 18% cited natural resource management, 14% mentioned climate change, while 10% reported that these topics were not addressed.

Frequency of sustainability discussions by biology teachers: 37% of students stated that their teachers always discussed sustainable development topics, 32% reported discussions often, 21% occasionally, and 10% never.

Perceived importance of sustainability topics for the future: 36% of students considered sustainability topics very important, 43% moderately important, and 21% not important.

Motivation to act in environmental protection after biology lessons: 47% of students felt always motivated, 32% often motivated, 11% rarely motivated, and 10% never motivated.

Actions undertaken to contribute to sustainable development: 33% reported engaging in recycling practices, 22% in the use of renewable energy, 43% participated in school environmental activities, and 2% did not engage in any of these activities.

Teacher Questionnaires:

Frequency of integrating sustainability topics in biology lessons: 48% of teachers reported always integrating these topics, 23% often, 19% rarely, and 10% never.

Perceived scientific preparedness to teach sustainability: 46% of teachers felt always prepared, 30% often prepared, 17% rarely prepared, and 7% never prepared.

Resources used for teaching sustainability concepts: 45% of teachers used textbooks, 20% online resources, 25% practical activities, and 10% did not use any of these resources.

Training related to sustainability teaching: 36% of teachers reported always receiving training, 38% often, 15% rarely, and 11% never.

Assessment of student engagement in sustainability-related lessons: 52% of teachers perceived students as always highly engaged, 22% often engaged, 18% occasionally engaged, and 8% never engaged.

Conclusions

The role of biology in promoting education for sustainable development (ESD) in upper secondary education is both significant and timely, given contemporary environmental challenges and the need to raise awareness among younger generations. Biology, as the science of life and ecological interactions, plays a central role in developing competencies necessary for sustainable development. It enables students to understand natural processes and the impacts of human activities on the environment, providing the foundational knowledge required to foster responsible attitudes and behaviors. Concepts such as life cycles, biodiversity, and ecosystems form the basis for understanding the importance of environmental conservation.To promote ESD, biology teachers employ various pedagogical methods, including group work, discussions, practical projects, and laboratory experiments. In this study, 21% of students reported coverage of human impact on the environment, 37% biodiversity and its conservation, 18% natural resource management, and 14% climate change. These approaches help students link theoretical knowledge with practical applications and develop problem-solving skills related to environmental challenges. Thematic teaching that addresses socio-scientific issues—such as biodiversity, climate change, natural resources, and global health—enhances critical thinking and environmental awareness, empowering students to actively engage in solution-finding.Survey results indicate that approximately 57% of participants perceive a supportive emotional learning environment as highly motivating, fostering long-term learning. Students with positive perceptions of their competence in biology perform better academically and develop constructive attitudes toward the subject. ESD integration within biology and secondary education is widely accepted by teachers (88%), with over two-thirds (61–75%) incorporating sustainability topics into curricula and practical activities. However, a notable gap remains, as 45% of respondents consider the coverage of sustainability topics in regular lessons insufficient.These findings underscore the importance of structured, supportive, and resource-rich pedagogical practices in biology to maximize the development of students' knowledge, skills, and attitudes toward sustainable

development. Effective integration of ESD requires not only curriculum design but also continuous teacher training, appropriate teaching resources, and a learning environment that motivates and empowers students to take an active role in environmental stewardship.

Learning through analysis in education: Using data to improve student learning

Sara Pupe

Department of Biology, Aldent University, Albania

Abstract

In today's technology-driven world, information is continuously collected regarding individuals' activities both online and offline, leading us into the era of big data. This development has made it possible for learning analytics to revolutionize modern education by transforming data into actionable knowledge. It is the key to understanding how students learn, enabling subject instructors to adapt educational experiences to individual needs and enhance overall learner performance.This study examines the impact of data analytics on improving student learning in both pre-university and higher education in Albania. Institutions can use learning analytics to monitor student engagement, participation, and performance during a lesson. The research was conducted at the University of Tirana, Faculty of Natural Sciences, Aldent University, as well as at several secondary schools: "Petro Nini Luarasi," "Andon Zako Cajupi," "Sinan Tafaj," "18 Tetori," and "Jani Nushi."In total, the study included: 12 subject teachers (Mathematics, Albanian Language, Computer Science, Biology), 8 school principals, 50 high school students, and 60 university students, using anonymized data from learning management systems. The results indicate that the use of pedagogical dashboards and predictive analytics assists teachers in timely identification of struggling learners and in personalizing interventions, while also impacting students' comprehension and overall learning outcomes.Furthermore, the study highlights challenges such as the lack of teacher training in data interpretation and the absence of integrated school-level strategies. The conclusions emphasize the necessity of fostering a data-use culture in education, one that is grounded in ethics, transparency, and technological competence.

Keywords: analysis, educational data, performance, assessment, competencies, strategy

Objective of the Study

The aim of this paper is to analyze the ways educational data can be used for the systematic improvement of learning outcomes, to evaluate the effect of analytical interventions on motivation and performance, to identify challenges and opportunities related to the integration of data analytics into educational decision-making, and to produce a correlational report on institutional, technical, and ethical challenges.

Methodology

This study combines qualitative and quantitative approaches to analyze the use of data in improving learning in secondary education in Albania.

Conclusion

The findings of this study demonstrate that the use of data analytics in education can serve as a powerful tool for improving student outcomes, provided it is implemented carefully and in a structured manner.

Keywords: Analysis, Educational Data, Performance, Assessment, Competencies, Strategy

Introduction

Over the past decade, education has undergone a profound technological transformation, with particular emphasis on the integration of Learning Analytics (LA) as a means to enhance learning outcomes in both secondary and higher education. Contemporary approaches increasingly capitalize on the processing of vast quantities of digital traces—ranging from platform logins, time on task, and assignment performance to forum participation and reading duration. These traces enable educational systems to move beyond a reactive, content-delivery orientation toward a proactive, personalized, and evidence-based model of instruction. Consequently, the incorporation of data-driven approaches is reshaping how teaching and learning processes are conceptualized, monitored, and supported.The field of Learning Analytics has consolidated itself internationally as a pivotal instrument for guiding evidence-informed decision-making among educators, learners, and policymakers (Siemens & Long, 2011). While

initially prominent in technologically advanced contexts, LA has increasingly been applied in emerging educational systems such as Albania, where the gradual digitalization of learning environments has generated new opportunities for systematic analysis of learner performance and engagement.The present study seeks to investigate the extent to which the implementation of learning analytics contributes to the improvement of student learning in Albanian upper secondary schools and universities. Data were collected from five public high schools in Tirana—"Petro Nini Luarasi," "Andon Zako Çajupi," "Sinan Tafaj," "18 Tetori," and "Jani Nushi"—as well as from the University of Tirana and Aldent University. Employing a mixed-methods design, the study combined quantitative data (surveys administered to 70 secondary school pupils, 100 university students, 20 teachers, and 10 institutional leaders) with qualitative insights (interviews with school principals and document analysis). Findings revealed a statistically significant improvement in academic performance, with an average increase of 12% in quarterly results among students who received data-driven interventions.Aligned with international scholarship (Papamitsiou & Economides, 2014; Ifenthaler & Yau, 2020), the findings underscore that the effective use of data in educational settings extends beyond technological access. It requires sustained professional development, the cultivation of evidence-based decision-making cultures, and the strengthening of teacher–student relationships. At the same time, several systemic challenges were identified, including the absence of structured training for educators in data interpretation, a lack of standardized evaluative instruments, and persistent ethical concerns related to transparency, accountability, and data privacy (Slade & Prinsloo, 2013).Accordingly, this research is guided by two overarching questions:

To what extent does the use of individualized dashboards—providing learners with real-time insights into their engagement and progress—affect self-regulation and academic performance?

How do teachers utilize pedagogical analytics to diagnose learner engagement and progress, and what types of interventions are subsequently implemented based on these insights?

Literature Review

Within the scholarly discourse, *Educational Data Mining* (EDM) and *Learning Analytics* (LA) are widely recognized as two interrelated yet distinct fields that leverage data from diverse learning environments with the overarching aim of understanding and enhancing teaching and learning processes. Romero and Ventura (2024) provide a comprehensive overview of the evolution of these domains, detailing methodological approaches, learning contexts, and emerging research trajectories. Their synthesis highlights that while EDM predominantly focuses on uncovering hidden patterns in educational data through classification and clustering algorithms, LA emphasizes the transformation of these patterns into actionable insights for instructors, learners, and policymakers.A systematic review conducted by Kaliisa et al. (2023) on Learning Analytics Dashboards (LADs) revealed that their direct impact on academic achievement has generally been modest. Nevertheless, LADs demonstrated a stronger influence on learner engagement and participation, thereby underscoring their potential as motivational and self-regulatory tools. Complementarily, Viberg and Grönlund (2021) argue that despite growing interest, empirical evidence concerning the large-scale pedagogical impact of LA remains scarce. They call for deeper exploration into pedagogical practices and educators' needs to ensure the meaningful integration of LA into teaching and learning.Kaliisa et al. (2023), in their review of 38 studies, examined the effects of LA dashboards on academic achievement, motivation, participation, and student behavior, concluding that dashboards contribute variably across these dimensions. Similarly, Pathirana et al. (2024) report that the adoption of data analytics in higher education—particularly during the COVID-19 pandemic—has supported improvements in student performance, informed pedagogical interventions, and guided institutional decision-making.Furthermore, a large-scale review of 400 studies in distance education (2023) indicated that more than 52% of the included research reported positive effects of LA, such as enhanced academic outcomes, behavioral analysis, and early prediction of academic failure. However, the review also noted contextual limitations, including restricted implementation in resource-constrained environments and significant financial costs associated with LA adoption.Romero and Ventura (2024) additionally emphasize that the dual trajectories of EDM and LA must be understood in relation to one another. While EDM advances the technical frontier of pattern discovery, LA seeks to translate such discoveries into pedagogically meaningful practices, thereby positioning itself as a critical bridge between data-driven insights and evidence-based educational decision-making

Methodology

This study adopted a mixed-methods approach, combining quantitative and qualitative strategies to investigate the relationship between the use of learning analytics tools and academic performance, as well as teacher perceptions of student engagement. The central premise of the research is that students and university learners who utilize learning analytics tools demonstrate higher academic performance, while teachers who integrate data analytics into their instructional practices report increased student engagement.

Data Collection Instruments – The primary instrument for this study was a structured questionnaire, designed to capture both quantitative and qualitative data. The questionnaire included:

Closed-ended questions to collect quantitative data and facilitate statistical analysis;

Open-ended questions to elicit in-depth insights, perceptions, and comments from participants.

Sampling – A random sample was selected, comprising 70 high school students, 100 university students, 20 teachers, and 10 institutional leaders. Data collection was conducted over a two-week period.

Data Analysis – Quantitative data were analyzed using statistical software (SPSS), allowing for descriptive and inferential analyses of numerical responses. Qualitative data from open-ended questions were coded and categorized to identify recurring themes and patterns, enabling thematic analysis.

Ethical Considerations – Participants' personal information was handled with strict confidentiality, ensuring compliance with ethical research standards and data protection protocols.

Results and Discussion

The findings from the survey provide comprehensive insights into the use and perceived impact of learning analytics (LA) among teachers, school leaders, and students in both secondary and higher education contexts in Albania.

Teacher and Leadership Use of Data – A majority of educators (68%) reported that they fully use data to improve instructional practices or learner support, while 13% disagreed and 11% were neutral. This indicates a generally positive adoption of data-driven instructional practices, though some educators remain hesitant.

Impact on Student Learning Outcomes – Regarding the effect of data analytics on student results, 59% of respondents strongly agreed that it contributed to performance improvement, 33% disagreed, and 8% were neutral. Additionally, 58% reported that the use of data always enhanced students' learning outcomes, 29% observed improvement frequently, and 13% noted no effect.

Preferred Applications of Data – Teachers and students indicated that learning analytics should be more extensively used for: individualized support (27%), fairer assessment (48%), and quicker feedback (23%), while 2% were unsure.

Training and Professional Development – Regarding data interpretation training, 43% of institutions provide formal training by specialists, 36% do not offer training, and 21% provide informal peer-based guidance. These findings underscore the need for structured professional development to maximize LA effectiveness.

Practical Use of Data in Instruction – Data were primarily used for lesson planning (51%), grouping students by similar proficiency (21%), and preparing supplementary materials (26%), whereas 2% of educators did not use the data at all. Monitoring student performance on learning platforms occurred daily for 47%, weekly for 36%, occasionally when grading (13%), and not at all for 4% of respondents.

Adaptation and Feedback – Data-driven adaptation of teaching to students' needs was fully endorsed by 47% of respondents, while 17% strongly disagreed and 36% were neutral. Feedback from students was perceived as consistently helpful by 41%, frequently helpful by 15%, rarely helpful by 30%, and never helpful by 14%.

Motivation and Support – The use of learning analytics was reported to positively influence motivation, with 49% indicating a strong positive effect, 22% often, 25% occasionally, and 4% never. Support to enhance data use included additional training (60%), technological tools (31%), and peer support (9%).

Frequency and Tools for Data Analysis – Teachers adapted instructional methods based on data always (29%), often (27%), rarely (21%), and never (23%). Tools for analysis included Excel (38%), learning management platforms (39%), and specialized analytics software (23%).

Student Understanding and Perceived Usefulness – In terms of supporting students' comprehension of their progress, 23% reported that teachers always assist them, 27% sometimes, 30% rarely, and 20% never. Students perceived the platforms as always useful (29%), often useful (27%), and not useful (27%

Conclusions

In an era where education faces increasingly complex challenges and rising expectations, learning analytics (LA) emerges as a powerful tool to enhance quality and equity in learning. Beyond a technical procedure, LA represents a strategic approach that places the learner at the center of the educational process, empowers teachers, and fosters collaboration among educational leaders. When combined with critical reflection and human-centered practices, the use of data has the potential to transform traditional schools into dynamic learning environments where every student has a genuine opportunity to reach their full potential.The findings of this study demonstrate that the implementation of data analytics can significantly improve instructional practices and directly influence student outcomes, provided it is applied systematically and thoughtfully. Specifically, approximately 47% of students and university learners had access to their performance data on learning platforms, enabling more informed self-monitoring. Teachers with access to detailed dashboards on student progress were able to identify learners facing difficulties earlier and implement more effective support strategies.A recurring challenge observed among teachers and institutional leaders is the limited availability of ongoing professional training by field specialists, which constrains lesson planning and instructional strategy. Consequently, 60% of educators and leaders reported the need for additional structured training, 31% emphasized the need for improved technological tools, and 9% identified peer support as necessary.Moreover, 49% of respondents indicated that the use of learning analytics positively influenced student motivation. However, the role of teachers in helping students interpret their progress remains limited, with only 23% regularly assisting learners in understanding their academic development.Overall, these benefits and challenges suggest that, when implemented effectively, learning analytics can substantially enhance both student learning and the quality of instruction. The findings underscore the need for ongoing professional development, robust technological infrastructure, and active teacher engagement to fully realize the potential of data-driven educational practices.

ORAL PRESENTATION

Wine sector in Albania: Challenges and opportunities for geographical indications protection

Aleksander Petre[1], Dritan Topi[2]*

[1]Faculty of Natural Sciences, University of Tirana, Department of Industrial Chemistry, Blvd Zogu 1, 1000, Tirana, Albania
[3]Faculty of Natural Sciences, University of Tirana, Department of Chemistry, Blvd Zogu 1, 1000, Tirana, Albania

Abstract

Albania's wine industry benefits from favorable Mediterranean climate and a rich cultural heritage, yet it faces obstacles in modernization, market competition, and protecting geographical indications (GIs). This review explores historical and current trends in grape growing and winemaking, based on FAOSTAT data and national development strategies. Indigenous varieties like Kallmet, Sheshi i Zi, and Shesh i Bardhë are central to Albania's wine identity, setting it apart from international cultivars. The paper also investigates global trade patterns, authentication methods, and legal frameworks to combat counterfeiting and safeguard product authenticity. The results highlight the importance of developing strong traceability systems and aligning with EU standards to boost consumer trust and elevate Albania's wine reputation worldwide. Recommendations focus on promoting native grape varieties and enhancing GI protections to maintain competitiveness in international markets.

Keywords: Albanian wine sector, Autochthonous grape varieties, Geographical indication, traceability

Overvie of Wine Production in Albania

Albania's Mediterranean climate—with hot summers and mild winters—supports perennial crops and a long tradition of viticulture. In 2009, vineyards covered 9,800 acres, and under the national plan, 300–500 acres of new vineyards are planted each year. Currently, 90 enterprises produce wine, 77% of which process less than 100 tons per year. About 70 are family-run micro-wineries, while the 20 largest producers account for 80% of processed grapes.

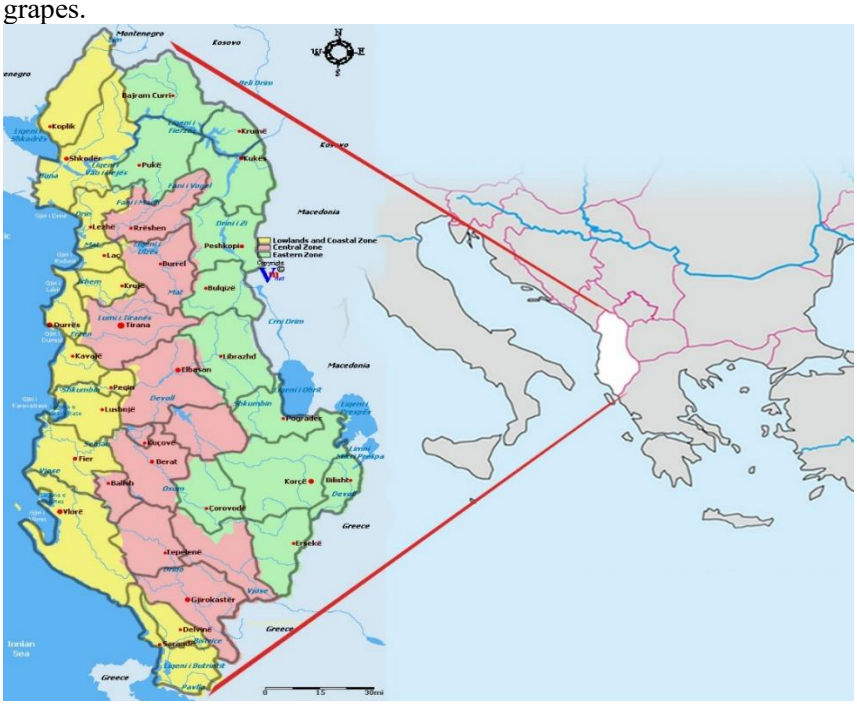

Figure 1. Wine regions of Albania according to Vinnet.

Production of raw material (grapes)

According to statistics, 90 enterprises in our country are engaged in wine processing and production. Of these, about 77% have a processing capacity of less than 100 tons/year, and 70 enterprises are considered family-run micro-wineries. It is emphasized that the 20 largest producers account for 80% of the processed grapes.

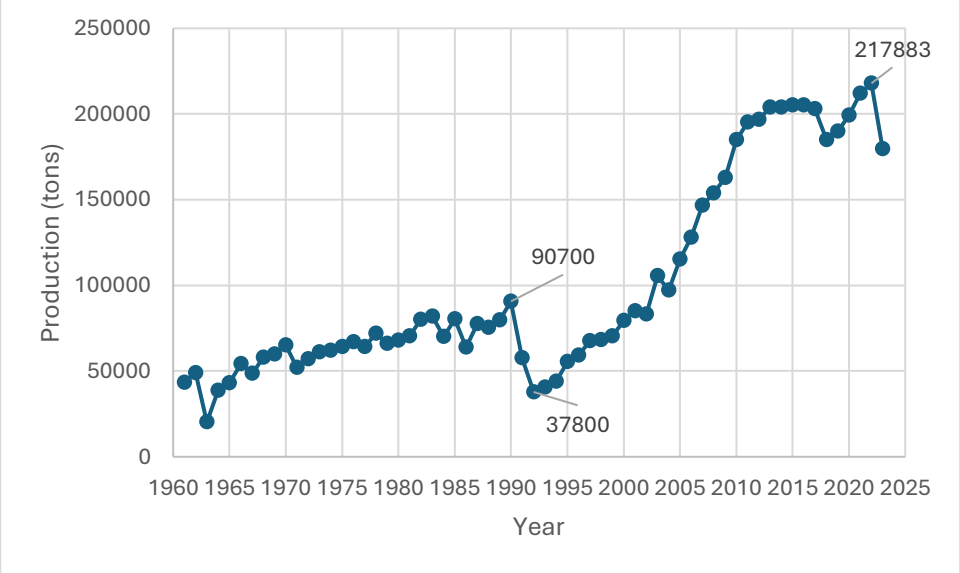

Figure 3. Grape production according to FAOSTAT, 1961-2022 period.

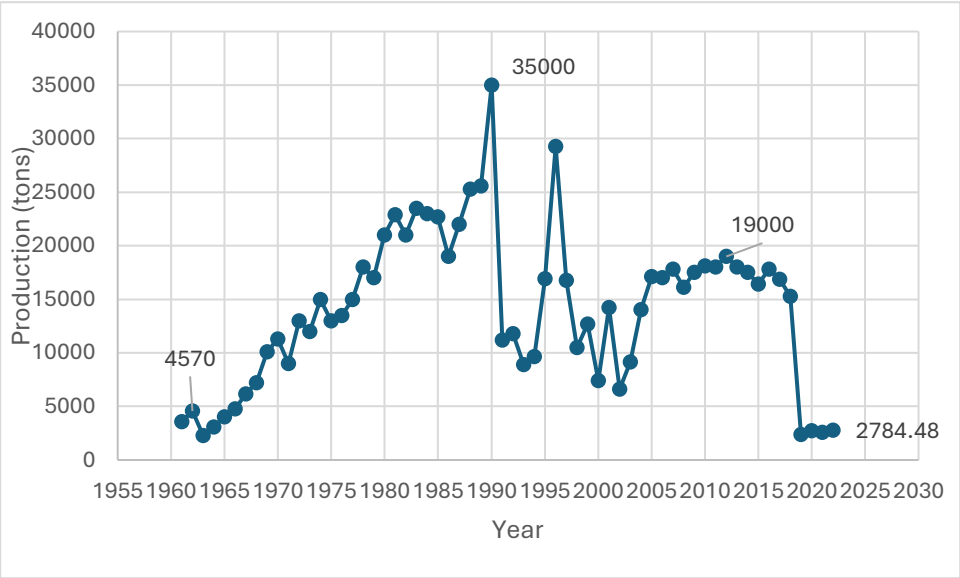

Figure 4: Wine production in Albania, 1961-2022 (Source: FAOSTAT, 2024)

Albania's Viticulture Advantage

The pedoclimatic conditions in Albania are conducive to viticulture, supporting a range of local cultivars recognized for their quality and productivity. Red wines crafted from Vlosh grapes stand out distinctly, whereas the local white varieties differ significantly from Chardonnay (Sotiri et al., 1996; Cakalli et al., 2003).

Viticultural Advantages and Indigenous Varieties

Albania's pedoclimatic conditions favor high-quality local cultivars. Notable white varieties include Shesh i Bardhë, Debina e Bardhë Leskoviku, Serina e Bardhë, and Kryqësi, while red varieties include Vlosh, Kallmet, Sheshi i Zi, Mavrud, Koteka e Zezë, and Serina e Zezë. These grapes have high sugar content and distinctive aromas, producing wines with unique profiles that set Albanian products apart in global markets.

Varieties of local origin (autochthonous) for the production of white wines

Sheshi i Bardhë

The most notable local variety, cultivated for centuries in Tirana, Durrës, and Kavaja regions of central Albania, thrives in a Mediterranean climate near the Adriatic Sea. It is named after the village of Shesh in the Ndroqi area, where it is traditionally grown. When fully ripe, it contains 24-26% sugar and 6-7% acidity. In the lower coastal zone, this variety produces high-quality white wines, both dry and semi-dry, characterized by a rich aroma and body.

Figure 5. Wine regions of Albania, and indigenous grape varieties.

Debina e bardhë Leskoviku
Debina Leskoviku is one of the oldest local grape varieties in southeastern Albania. It is primarily grown in regions such as Përmeti, Leskoviku, Korçë, Skrapar, and Berat. When fully ripe, it contains 22-24% sugar and 5.5-6% acidity, and it is known for producing high-quality dry table wines with a desirable alcohol content.

Serina e bardhë

This white grape variety is among the oldest local types, commonly found throughout southern and southeastern Albania. It serves as a cornerstone for viticulture in the Korça, Skrapar, Berat, and Kolonja regions. This variety is used to produce high-quality table wines. It has a sugar content of 22-24% and an acidity level of 5.8-6.2%.

Kryqësi (Sinambel)
This local variety has been developed through the efforts and selection of our ancestors. It is commonly found in the administrative regions of Leskovik, Këlcyra, Përmet, and Tepelena. It ripens in the medium-late period and has a strong ability to accumulate sugar in the grain. In Leskovik and Përmet, it has produced 23-26% sugar content and an overall acidity of 6.2-6.7%.

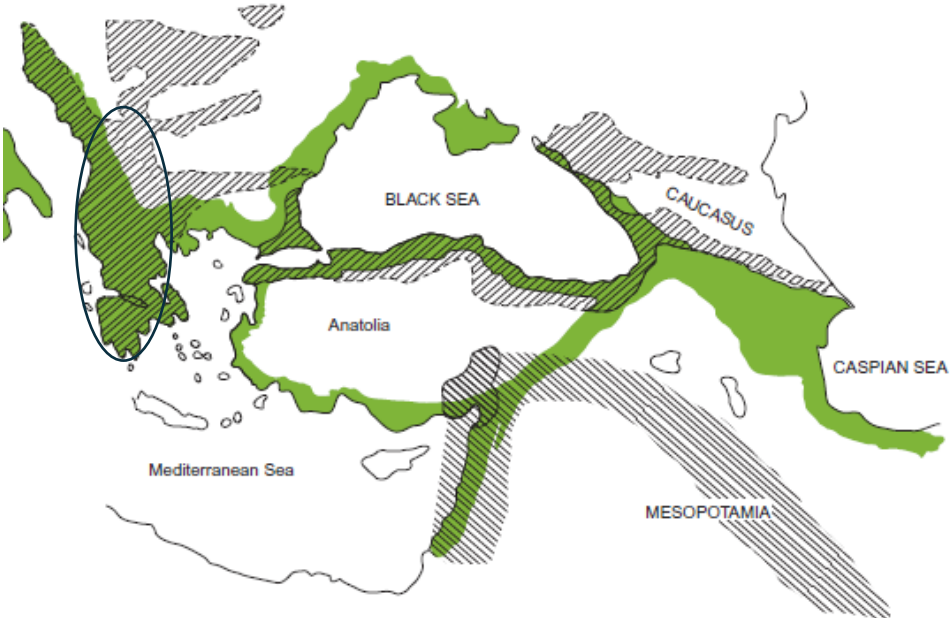

Figure 5. Comparison of the geographic distribution of *Vitis vinifera* L. sylvestris (Shaded). Quercus sessilis (right-slanted lines) and the origin of agriculture (left-slanted lines), based on the data from Levadoux (1956).

Local varieties for the production of red wine

Vlosh

It is one of the oldest red grape varieties grown in the regions of Vlora, Himara, Narta, Saranda, Berat, Lushnja, Gjirokastra, and Përmet. It holds the largest share of vineyards in our country. This variety ripens late, with an active growing period of about 180 days and a high-temperature tolerance of 36.0–37.0 °C. In these areas, Vlosh has accumulated 22-25% sugar and low acidity levels of 3.4-4.5%. It is used to produce dessert wines, alcoholic wines, and liqueurs. A drawback of this variety is its weak color; therefore, blending it with wines from more intensely colored varieties, such as Mavrud, is recommended.

2. Kallmet

Kallmet, also known as Gjashore, Zadrimore, and Kallmete, is an ancient local grape variety commonly found in the hills of Lezha and Shkodra, as well as around Lake Shkodra, where it has been cultivated for centuries due to its high quality. The Romans brought it to Central Europe, where it acquired various names such as Gemza, Tokai (Nero di Scutari), Kadarka, Branicevka, and Lugojane. In addition, Kallmet is cultivated in Tirana, Lushnja, Përmet, and Leskovik. This variety produces high-quality, dry table wines that are well-balanced, with good color and a distinctive bouquet, making it a prized grape in local winemaking.

Shesh i Zi

It is a variety of local origin, cultivated in the Ndroqi, Shesh, and Tirana areas, from which it gets its name. Today, it is widespread throughout many parts of Albania, including Krujë, Shkodër, Lezhë, Elbasan, Lushnja, and Durrës. Sheshi i zi performs well in loose soils with a high limestone content. Under such conditions, it accumulates 23–25% sugar. This variety yields very high-quality dry alcoholic wines with a distinctive taste and aroma.

Mavrud cv.

It is believed to have originated in Thrace; today, it is regarded as one of the oldest varieties among the Balkan peoples. It is common in Shkodër, Lushnja, and Tirana. It reaches high sugar levels (22–25%). The wine made from this variety is very full-bodied, dark in color, rich in flavor, and well-balanced, especially when aged. It also functions as a complementary variety for pairing with lighter-colored wines.

Koteka e Zezë cv.
It is one of the oldest grape varieties in our country, and it is common in the Përmet and Leskovik regions. In these areas, it ripens by the end of September. It accumulates high sugar levels (22-27%) and is used to produce high-quality table wines.

Serina e Zezë cv.
It is locally produced and has long been known in the regions of Korca, Pogradec, Leskovik, Berat, and Skrapar. It is a medium-ripening variety that accumulates sugars at a good level of 19-21%. It produces high-quality, balanced wines with distinctive characteristics upon aging.

Global Wine Trade Overview
By 2010, the export market accounted for more than 30% of total global production, indicating that the international wine trade had experienced significant growth since 2000. This boom was spurred on by a rise in consumption in North America and Northern Europe in the 1990s, as well as an increase in exports from manufacturers in the Americas. The OIV research states that world wine production in 2017 was around 246.7 million hectoliters. In contrast, global imports reached 22.6 billion euros for 3.4 million hectoliters by 2011. Italy, France, and Spain have remained the top producers (Mariani, Pomarici, and Boatto, 2012).

Wine Authentication and Traceability
Guaranteeing the authenticity and traceability of wine is a significant global issue. Quality control procedures are obligatory in numerous nations, including the EU and the USA, to safeguard customers against production faults and to avert illicit adulteration. Traceability guarantees that products can be monitored throughout all phases of manufacture and distribution, hence augmenting consumer confidence in health, quality, and safety. Key legislation encompass Directive (EU) 178/2002, which establishes a comprehensive framework for food safety and traceability, and EC Directive 986/89, which governs the transit of wine throughout the EU, mandating authenticity documentation. ISO Standards: ISO 22000:2005 incorporates traceability inside HACCP systems; ISO/FDIS 22005:2007 delineates principles for food chain traceability.
.
Elements of a Traceability System
Six core components include the following:
- Product Traceability – Tracking the physical location.
- Process Traceability – Documents activities throughout the production process.
- Genetic Traceability – Determines the genetic source.
- Input Traceability – Monitors the movement of additives and raw materials.
- Disease and Pest Tracking – Monitors risks of contamination.
- Analytical Measurement Traceability – Guarantees the precision of measurements (Opara, 2003).

Geographic Indication and Viniculture Promotion in Albania
Geographical indications (GIs) play a crucial role in the wine sector because they legally protect the name of a product that originates from a specific region and possesses qualities or a reputation linked to that origin. For Albanian wines, GIs help differentiate local products from international competitors by emphasizing the unique characteristics of indigenous grape varieties and traditional production methods, which strengthens brand identity and cultural heritage. Additionally, robust GI protections build consumer trust, prevent counterfeiting, and align national standards with EU legislation. Making it easier for producers with EU regulations. Making it easier for producers to access global markets and maintain competitiveness. Some key outcomes are:
1. Modernization of Facilities – Upgrading equipment and processes to improve quality and efficiency.
2. Strengthening Geographical Indication (GI) Protection – Ensuring authenticity and origin claims to differentiate Albanian wines globally.
3. Implementing Traceability Systems – Aligning with international standards to secure supply chains and prevent fraud.
Additionally, promoting indigenous grape varieties is highlighted as a way to enhance market differentiation and build trust internationally. In short, the sector needs modernization, robust GI frameworks, and traceability to compete globally and protect its cultural heritage.

Wine Counterfeiting and Legislation

Counterfeiting encompasses dilution, adulteration, blending with inferior wines, and misrepresentation of provenance (Holmberg, 2010). Legislation differs throughout several states. California, USA, allows limited water addition during fermentation, although EU legislation forbids it. Specific terminology
is interpreted variably; for instance, Italy and Chile differentiate between 'adulteration' (modifications) and 'falsification' (counterfeit items).

Conclusions

Albania's wine sector holds significant potential due to its favorable Mediterranean climate and diverse autochthonous grape varieties. However, modernization challenges, limited market competitiveness, and insufficient protection of geographical indications remain critical obstacles. Strengthening traceability systems and harmonizing national legislation with EU standards are essential to ensuring authenticity, preventing counterfeiting, and building consumer trust. Promoting indigenous varieties such as Vlosh, Kallmet, and Sheshi can be a strategic advantage for differentiating Albanian wines in global markets. Future efforts should focus on integrating advanced quality control measures, expanding export opportunities, and leveraging geographical indications to support sustainable economic growth and cultural preservation.

*Sorumlu yazar e-mail: osman.ozsahin@uskudar.edu.tr

Özet

Sitomegalovirüs (CMV), Herpesviridae ailesine ait, zarflı ve çift zincirli DNA yapısına sahip bir virüs olup konjenital enfeksiyonların en yaygın nedenlerinden biridir. Bu çalışmada, prenatal dönemde amniyotik sıvı örneğinde CMV DNA varlığının araştırılması ve elde edilen bulguların literatür verileriyle karşılaştırılması amaçlanmıştır. Ocak 2022 – Ocak 2024 tarihleri arasında İstanbul Üniversitesi İstanbul Tıp Fakültesi Kadın Hastalıkları ve Doğum Anabilim Dalı'na başvuran 20–52 yaş aralığındaki toplam 234 hastanın amniyotik sıvı örnekleri incelenmiş ve gerçekleştirilen analizler sonucunda 11 hastada (%4,7) CMV DNA pozitifliği saptanmıştır. Pozitif olguların yaş aralığı 21–31 olarak belirlenmiştir. Elde edilen pozitiflik oranı, literatürde bildirilen (Goegebuer ve ark., 2009) %14,5 ve (Simonazzi ve ark., 2017) %13,4 çalışmalarında bildirilen oranlardan düşük bulunmuştur. Bu farklılığın popülasyon özellikleri, bölgesel değişkenlikler, örneklem büyüklüğü ve tanı yöntemlerindeki farklılıklardan kaynaklandığı düşünülmektedir. Sonuçlar, prenatal dönemde CMV enfeksiyonlarının sıklığının azalma eğiliminde olabileceğini, ancak enfeksiyonun doğurganlık çağındaki kadınlarda hâlen görüldüğünü göstermektedir. CMV enfeksiyonu, konjenital enfeksiyonların en önemli etkenlerinden biri olmaya devam etmekte olup, prenatal dönemde rutin tarama ve erken tanı uygulamalarının maternal ve fetal sağlığın korunmasında büyük önem taşıdığı sonucuna varılmıştır.

Anahtar Kelimeler: Sitomegalovirüs, Amniyotik sıvı, Prenatal tanı

Evaluation of molecular test results in congenital cytomegalovirus (CMV) infections at a university hospital

Abstract

CMV is an enveloped, double-stranded DNA virus belonging to the Herpesviridae family and is one of the most common causes of congenital infections. This study aimed to investigate the presence of CMV DNA in amniotic fluid samples during the prenatal period and to compare the obtained findings with data reported in the literature. Between January 2022 and January 2024, amniotic fluid samples from a total of 234 patients aged 20–52 years who were admitted to the Department of Obstetrics and Gynecology, Istanbul University, Istanbul Faculty of Medicine, were analyzed. CMV DNA positivity was detected in 11 patients (4.7%), and the age range of CMV-positive cases was determined as 21–31 years. The positivity rate observed in this study was lower than those reported by (Goegebuer et al.,2009) %14.5 and (Simonazzi et al., 2017) %13.4 This difference may be attributed to population characteristics, regional variations, sample size, and differences in the sensitivity of diagnostic methods. The results suggest a possible decreasing trend in the frequency of prenatal CMV infections; however, the persistence of cases among women of reproductive age indicates that CMV remains a relevant concern. CMV infection continues to be one of the leading causes of congenital infections, and routine screening and early diagnosis during the prenatal period are of great importance for the protection of maternal and fetal health.

Keywords: Cytomegalovirus, Amniotic fluid, Prenatal diagnosis

GİRİŞ

CMV, Herpesviridae ailesinden çift zincirli zarflı bir DNA virüsüdür (Kemaloğlu ve ark., 2023). Virüsün 100 nm çapında ikozahedral bir nükleokapsiti vardır. Virüs genomu tegument veya matris olarak tanımlanan proteinli bir tabaka ile çevrilidir. Tegument veya matris, çok sayıda viral glikoprotein içeren bir lipit çift tabakasıyla çevrilidir. (Landolfo ve ark., 2003). CMV genomu 253 kb boyutunda olup insan herpesvirüsleri içinde en büyük genoma sahiptir. Yapısında 60 dan fazla glikoprotein bulunur. Başlıca glikoproteinlerinden biri olan Glikoprotein B (gB) (gpUL55), tanımlanmış 5 antijenik belirleyiciye (AD1-AD5) sahiptir. Bunlar nötralize edici antikorların hedefi olup virüsün hücreden hücreye bulaşmasını ve enfekte hücrelerin füzyonunu sağlar. CMV zarfında bulunan gB, zarftaki toplam protein kütlesinin %50'sinden fazlasını oluşturur ve konak bağışıklık tepkisini uyarır. Glikoprotein B (gB), genotipleme açısından en çok incelenen protein olup nötralize edici antikorlar için bir hedef bölgedir. Bulaşma yollarını ve coğrafi kökeni belirlemek için belirteçtir (Coşkun ve ark., 2023). CMV hamilelik esnasında bulaştığında konjenital enfeksiyona sebep olan yaygın bir viral patojendir. İntrauterin bulaşmalarda fetüste büyüme kısıtlamasına, gelişimsel gecikmelere, veya uzun vadeli sekeller oluşturabilir (Sayar ve ark., 2025). Virüsün inkübasyon süresi 4-12 hafta olup bulaş yolları yakın temas, idrar, kan, tükürük yada genital salgılar gibi vücut sıvıları ve kan yoluyla olmaktadır. Anneden bebeğe gebelikte plasenta yoluyla, doğum esnasında yada emzirme yoluylada geçebilmektedir. CMV vücuda girdikten sonra öncelikli olarak monosit, makrofaj ve endotelyal hücreleri enfekte eder; bununla birlikte, neredeyse tüm hücre tiplerinde çoğalma yeteneğine sahiptir. Virüs, kan dolaşımı aracılığıyla karaciğer ve dalağa ulaşır ve bu organlarda da çoğalmasını sürdürür. Monositler içinde latent (gizli) bir durum oluşturarak ömür boyu kalabilir. Virüs zaman zaman yeniden aktive olarak enfeksiyon tablosuna yol açabilir. Birincil ve ikincil enfeksiyonlarda olsun hem de aktivasyon evrelerinde olsun kan ve çeşitli vücut sıvılarında yüksek miktarda virüs tespit edilebilir (Kemaloğlu ve ark., 2023). CMV normal bağışıklığa sahip kişilerde asemptomatik hastalığa sebep olurken solid organ ve kemik iliği nakilli ve AIDS gibi bağışıklığı baskılanmış hastalarda mortalite ve morbiditiye neden olmaktadır (Coşkun ve ark., 2023)

MATERYAL METOT

Hastalara ait CMV DNA kantitatif testi sonuçları, hasta dosyalarındaki verilerden elde edilmiş ve değerlendirmeye alınmıştır. Çalışmamızda tam otomatik cobas® 6800 (Roche) sistemi kullanılmıştır. Cihazın çalışma prensibine göre hastalara ait plazma örnekleri, örnek yükleme ünitesine yerleştirilir. Barkodları ile numune otomatik olarak tanınmaktadır. Cihaz tarafında otomatik nükleik asit ekstrasyonu yapılarak örnek içindeki viral DNA izole edilir. İzole edilen nükleik asit sistem içindeki PCR master mix ile karıştırılır. Primer, enzimler ve prob reaksiyon karışımına eklenir. Real-Time PCR yöntemiyle hedef nükleik asit amplifiye edilir. Floresan sinyaller ile çoğalan DNA miktarı her döngüde ölçülür ve bu aşamada Ct (cycle threshold) değerleri belirlenir. Sistem amplifikasyon eğrilerini analiz ederek pozitif, negatif ya da şüpheli sonuçları gösterir. Tüm süreç sistem içinde otomatik olarak değerlendirilmektedir.

BULGULAR

Ocak 2022 - Ocak 2024 tarihleri arasında, İstanbul Üniversitesi İstanbul Tıp Fakültesi Hastanesi Cerrahi Tıp Bilimleri Bölümü, Kadın Hastalıkları ve Doğum Anabilim Dalı'na başvuran 20–52 yaş aralığındaki toplam 234 hastanın amniyotik sıvı örnekleri incelenmiştir. Gerçekleştirilen analizler sonucunda, 11 hastada (%4,7) CMV DNA pozitifliği saptanmıştır. CMV DNA pozitifliği tespit edilen hastaların yaş aralığı 21–31 olarak belirlenmiştir.

TARTIŞMA

Goegebuer ve ark., (2009) tarafından Kasım 2002 – Ekim 2006 tarihleri arasında yürütülen çalışmada, 282 hastanın 41'inde (%14,5) CMV pozitifliği saptanmış, pozitif olguların 35'inin yaş aralığı 22–37 olup ortalama yaşı ise 29 olarak tespit edilmiştir. Simonazzi ve ark., (2017) tarafından yapılan çalışmada ise, Ocak 2007 – Aralık 2014 döneminde incelenen 239 hastanın 32'sinde (%13,4) CMV DNA'sı pozitif bulunmuştur; hastaların yaş aralığı 18–44, ortalama yaşı 32 olarak tespit edilmiştir.

Bizim çalışmamız ile literatürde bildirilen oranlar karşılaştırıldığında, çalışmamızda saptanan pozitiflik oranının daha düşük olduğu görülmektedir. Bu farklılık, çalışmanın yürütüldüğü dönemdeki popülasyon özellikleri, bölgesel farklılıklar, örneklem büyüklüğü ve kullanılan tanı yöntemlerinin duyarlılığındaki değişkenlikler ile açıklanabilir. Ayrıca, son yıllarda gebelik takibi sırasında rutin serolojik taramaların artması ve prenatal hijyen farkındalığının yükselmesi, CMV enfeksiyonlarının sıklığında görece bir azalmaya yol açmış olabilir.

Öte yandan, yaş dağılımı açısından değerlendirildiğinde, pozitif olguların çoğunlukla 20'li yaşlarda yer aldığı görülmektedir. Bu bulgu, literatürde bildirilen verilerle paralellik göstermekte olup, CMV enfeksiyonunun doğurganlık çağındaki kadınlarda daha sık görüldüğünü desteklemektedir. Çalışmamızda elde edilen CMV pozitiflik oranı, literatürde bildirilen oranlardan düşük olmakla birlikte, genel eğilimle uyumludur. Bu durum, prenatal dönemde CMV enfeksiyonlarının hâlen önemli bir halk sağlığı sorunu olduğunu ve rutin tarama ile erken tanının önemini ortaya koymaktadır.

SONUÇ

Bu çalışma, prenatal dönemde amniyotik sıvı örneklerinde CMV DNA varlığının araştırılmasına yönelik olarak gerçekleştirilmiştir. Elde edilen bulgular, incelenen 234 olgunun %4,7'sinde CMV DNA pozitifliği saptandığını göstermiştir. Bu oran, literatürde bildirilen değerlerden düşük olmakla birlikte, prenatal CMV enfeksiyonlarının halen göz ardı edilemeyecek düzeyde olduğunu ortaya koymaktadır. Bulgular, özellikle doğurganlık çağındaki kadınlarda enfeksiyon riskinin devam ettiğini ve prenatal dönemde CMV taramasının erken tanı açısından önemini vurgulamaktadır.

Sonuç olarak, CMV enfeksiyonu, konjenital enfeksiyonların en sık nedenlerinden biri olmaya devam etmektedir. Bu nedenle gebelik sürecinde riskli grupların belirlenmesi, rutin tarama programlarının yaygınlaştırılması ve farkındalık çalışmalarının artırılması, hem maternal hem de fetal sağlığın korunması açısından büyük önem taşımaktadır. Ayrıca, daha geniş örneklemli ve çok merkezli çalışmalarla ülkemizde prenatal CMV enfeksiyonlarının gerçek prevalansının ortaya konulabileceği düşünülmektedir.

Özet

Uluslararası diabet federasyonunun verilerine göre diyabetin günümüzde yaklaşık 415 milyon insanı etkilediği tahmin edilmektedir. Tedavide ise temel yaklaşım diyabet tipine bakılmaksızın, ister egzersiz programları ister ilaçlarla olsun, hastaların kan glikozunu kontrol etmek zorunluluğunun olmasıdır. Kullanılan antıdiyabetik ilaçlar hasta popülasyonunda direncin oluşturulması, olumsuz etkilerin gelişmesi ve duyarlılıgın zayıflamasına kadar degişen bazı dezavantajlarına sahiptirler. Gelinen noktada son yıllarda tedavi yöntemlerinde kaydedilen önemli ilerlemelere rağmen diyabetik hastaların tedavisinin sonuçları hala mükemmel olmaktan uzaktır. Sunulan bildiride ülkemizin farklı bölgelerinde yetişen, Ada çayı (Salvia officinalis L.), Ayva (Cydonia oblonga Miller), Nar (Punica granatum L.), Papatya (Matricaria chamomilla), Sumak (Rhus coriaria L.), Yeşil çay (Comellasinensis) destekleyici tedavi ürünleri arasında yer alan ve antidiyabetik potansiyet taşıyabilecek olan bu bitkilerden elde edilen ekstrakların terapotik aktivitesinin in vitro ortamda araştırılmıştır. Her bitki örneği için farklı 7 numune toplanmıştır.Toplanan bitki örnekleri saf suyla yıkadıktan sonra +45 °C de etüvde ağırlık sabitleninceye kadar kurutulmuştur. Bitki ekstraktların yapılmasında (%80 etanol-su (v/v)) kullanılmıştır. Analiz için Standart kitler (Sigma-Aldrich'ten) kullanılmıştır. Ekstraktların analizinde Ketohexokinaz, Alfa-Amilaz, Alfa-glikozidaz, dipeptidil peptidaz-4, Aldoz redüktaz enzimin standart kitleri kullanılmıştır. Elde edilen bulguların varyans analizleri SPSS 15.0 bilgisayar programı kullanılarak gerçekleştirilmiştir. Araştırma kapsamında yer alan nar kabuğu, sumak meyvesi, yeşil çay yaprağı, ayva yaprağı, papatya çiçeği ve ada çayı bitkileri alfaglukozidaz, amilaz, ketoheksokinaz, aldoseredultaz ve dipeptidil piptidaz enzimleri bakımından inhibisyon göstermesine karşın aralarında fark istatistiksel olarak anlamlı bulunmamıştır ($p>0,05$).

Anahtar Kelimeler: Antidiyabetik aktivite, Bitkisel ekstraktlar, Enzim inhibisyonu, diyabet.

In vitro investigation of the enzyme inhibitory mechanisms of traditionally used antidiabetic medicinal plants

Abstract

According to the data of the International Diabetes Federation, diabetes is estimated to affect approximately 415 million people today. In treatment, regardless of the type of diabetes, whether through exercise programs or medications, patients must control their blood glucose levels. The antidiabetic drugs used have several disadvantages in the patient population, ranging from the development of resistance, the occurrence of adverse effects, and the weakening of sensitivity. At this point, despite significant progress made in treatment methods in recent years, the outcomes of diabetic patient care are still far from perfect.In the presented study, the therapeutic activity of extracts obtained from plants growing in different regions of our country—sage (Salvia officinalis L.), quince (Cydonia oblonga Miller), pomegranate (Punica granatum L.), chamomile (Matricaria chamomilla), sumac (Rhus coriaria L.), and green tea (Comellasinensis)—which are among the supportive treatment products and may have antidiabetic potential, was investigated in vitro. For each plant sample, seven different specimens were collected. After washing the collected plant materials with pure water, they were dried in an oven at +45 °C until

constant weight was achieved. For plant extraction, 80% ethanol–water (v/v) was used. Standard kits (from Sigma-Aldrich) were used for the analysis. Standard kits of the enzymes Ketohexokinase, Alpha-amylase, Alpha-glucosidase, dipeptidyl peptidase-4, and Aldose reductase were used in the analysis of the extracts. The variance analyses of the obtained findings were carried out using the SPSS 15.0 computer program. Within the scope of the study, although pomegranate peel, sumac fruit, green tea leaf, quince leaf, chamomile flower, and sage plants showed inhibition in terms of alpha-glucosidase, amylase, ketohexokinase, aldose reductase, and dipeptidyl peptidase enzymes, the difference among them was not found to be statistically significant ($p > 0.05$).

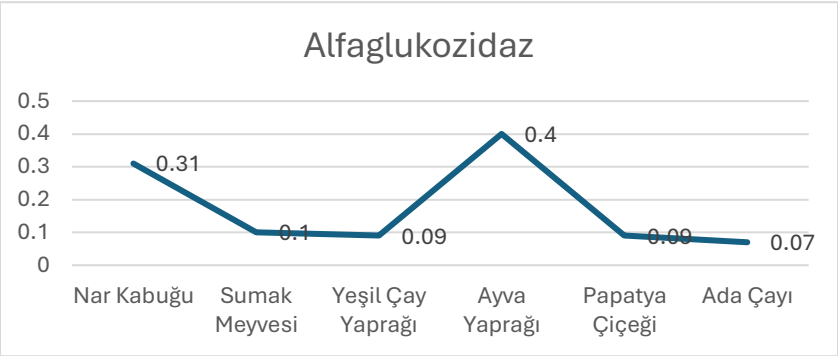
GİRİŞ

Diyabet, yaşadığımız yüzyılın en önemli sağlık sorunlarından biri olarak nitelendirilmektedir. Yapılan incelemelerde her 100 erişkinden yaklaşık 9unun (%8.8) diyabetli olduğu görülmüştür.üresel bazda sağlık harcamalarının %12si (673 milyar dolar) diyabet için kullanılm (World Health Organization, 2021). Oral olarak kullanılan sentetik antidiyabetik bazı ilaçlar hasta popülasyonunda direncin oluşmasından duyarlılığın azalmasına kadar değişebilen bazı dezavantajlara sahiptirler. Özellikle farklı etki mekanizmasına sahip olan bu ilaçlara rağmen diyabetik hastaların ancak yarısı hedef glisemik değerlere ulaşabilmektedir. projenin sonuçları DM nin tedavisinde yeni bakış açısı oluşturabilir. Doğal ürünler, özellikle bitkisel kökenli olanlar, umut vaat eden öncü adayları keşfetmek için ana kaynak oluşturmakta ve gelecek ilaç geliştirme programlarında hayati bir rol oynamaktadır. Kolay ulaşılabilirlik, düşük maliyet ve en az yan etki, bitki bazlı preparasyonların mevcut tedavilerin anahtar oyuncusu olmasını sağlamaktadır (Salehi ve ark., 2019). Ayrıca, birçok bitki istenmeyen yan etkilerden arınmış güçlü farmakolojik etkilere sahip biyoaktif kimyasalların zengin bir kaynağını sağlamaktadır. Sunulan tez çalışmasında ülkemiz coğrafiyasında yetişen söz konusu bitkilerin antidiyabetik aktivitelerinin araştırılması, bu yönde yeni tedavi ürünlerinin ortaya çıkmasına adaylık oluşturma potansiyeli taşımaktadır. \Dünya Sağlık Örgütü tüm üye ülkelere kendi ülkelerinin yerel ilaçlarını aktif olarak tanıtmalarını tavsiye etmiştir. Eski literatürde tarif edilen geleneksel bitki ürünlerinin modern tıpta kullanımı, çoğu durumda bilimsel kanıtların ve açıklamaların eksik olmasından muzdariptir. Sunulan tez önerisi fitoterapik ürünlerin etkinliğinin araştırmalarına katkı sağlamaktadır. Diğer yandan Söz konusu bitkilerin analizlerinin yapılması Anadolu halkının beslenmesinde şifalı olarak yer alan bu bitki bileşenlerinin ortaya konulması ve kıyaslanması, projenin özgün değerini oluşturmaktadır.

MATERYAL VE METOT

Bu çalışmada materyal olarak kullandığmız örnekler Türkiye coğrafyasında yetişen ve çeşitli şekillerde ve sıklıkla antidiyabetik etkisinden dolayı halk arasında kullanılan ve yenilebilen 6 bitkiden oluşmaktadır.. Bitki örnekleri yöredeki halk pazarlarından toplanmıştır. Bitkilerin sistematik olarak teşhisi:Türkiye Florası adlı esere bağlı kalarak yapılmıştır (Davis, 1985). Çalışmamızda örnek 6 Bitkilerin yerel isimleri ile bilimsel isimleri şöyledir: Ada çayı (Salvia officinalis L.), Ayva (Cydonia oblonga Miller), Nar (Punica granatum L.), Papatya (Matricaria chamomilla), Sumak (Rhus coriaria L.), Yeşil çay (Comellasinensis) bitkının farklı bölgelerden ve her örnek için farklı 7 numune halinde hazırlanamıştır.Toplanan bitki örnekleri iyice normal su ve sonra saf suyla yıkadıktan sonra +45 °C de etüvde ağırlık sabitleninceye kadar kullanılmıştır. Bitki ekstraktların yapılmasında (%80 etanol-su (v/v)) kullanılmıştır (Önem ve ark., 2020). Analiz için Standart kitler (Sigma-Aldrich'ten) satın alınmıştır. Ekstraktların analizinde Ketohexokinaz, Alfa-Amilaz, Alfa-glikozidaz, dipeptidil peptidaz-4, Aldoz redüktaz enzimin standart kitleri kullanılmıştır (Zengin ve ark., 2016). Elde edilen bulguların varyans analizleri SPSS 15.0 bilgisayar programı kullanılarak gerçekleştirilmiştir. Çoklu grupların karşılaştırılması varyans analizi (ANOVA) yapılarak POST-ho testler ile belirlenmiştir.

Çalışmada bitkilerin kullanılan kısımları bu şekildedir: Ada çayı (Toprak ustu kısımlar), Ayva (Yaprak), Nar (Kabuk), Papatya (Yaprak ve çiçek), Sumak (Meyve), Yeşilçay (Yaprak) Bitkilerin yerel isimleri ile bilimsel isimleri şöyledir: Ada çayı (Salvia officinalis L.), Ayva (Cydonia oblonga Miller), Nar (Punica granatum L.), Papatya (Matricaria chamomilla), Sumak (Rhus coriaria L.), Yeşil çay (Comellasinensis).



BULGULAR

Tablo 1 de gösterildiği gibi araştırma kapsamında yer alan nar kabuğu, sumak meyvesi, yeşil çay yaprağı, ayva yaprağı, papatya çiçeği ve ada çayı bitkileri alfaglukozidaz, amilaz, ketoheksokinaz, aldoseredultaz ve dipeptidil piptidaz enzimleri bakımından istatistiksel olarak anlamlı farklılık göstermemektedir ($p>0,05$). Enzim Değerlerinin Bitki Türlerine Göre İncelenmesi ise her bir enzime ait olacak şekilde grafikler ile sunulmuştur.

TARTIŞMA

Yapılan bu çalışmada beş hedef enzim olan alfa-glukozidaz, amilaz, ketoheksokinaz, aldosereduktaz ve dipeptidil peptidazın (DPP-4) antidiyabetik potansiyelleri, halk arasında antidiyabetik bitki olarak bilinen nar kabuğu, sumak meyvesi, yeşil çay yaprağı, ayva yaprağı, papatya çiçeği ve ada çayı üzerinde araştırılmıştır. Araştırma kapsamında yer alan nar kabuğu, sumak meyvesi, yeşil çay yaprağı, ayva yaprağı, papatya çiçeği ve ada çayı bitkileri alfaglukozidaz, amilaz, ketoheksokinaz, aldoseredultaz ve dipeptidil piptidaz enzimleri bakımından istatistiksel olarak anlamlı farklılık göstermemektedir. ($p>0,05$), Elde edilen bilgiler doğrultusunda, altı bitkinin ortak biyoaktif bileşikler ve fenolik profillere sahip olduğu çıkarımı yapılmaktadır. Yapılan çalışmalarda, çalışmamız kapsamında yer alan nar kabuğu, sumak ve yeşil çay gibi polifenol açısından zengin bitkilerin, karbonhidrat sindirim enzimleri üzerinde ellagik asit, gallik asit, kateşin ve flavonoidler vasıtasıyla benzer inhibitör etki gösterdiği bildirilmiştir (Zengin ve ark., 2016; Chakrabartty ve ark., 2022). Yapılan diğer çalışmalarda ise , benzer şekilde yüksek antioksidan kapasitesine sahip ayva, papatya ve ada çayı yapraklarının da DPP-4 ve aldose redüktaz gibi enzimler üzerinde içerdikleri quercetin glikozitlerinin, uçucu yağ bileşenlerinin ve kafeik asit türevlerin sayesinde inhibisyon potansiyeline sahip olduğu gösterilmiştir (Hwang ve ark., 2018; Rutkowska ve ark., 2023). α-glukozidaz ve α-amilaz enzimler Lamiaceae familyasına ait bitkiler olduğundan, inhibitör etki mekanizması iki enzimde ise benzer olduğu çalışmalarda bildirilmiştir (Etsassala ve ark., 2022; Gök ve ark., 2019). Yapılan çalışmalar ile uyumlu olarak bitkilerin biyokimyasal özeliklerinin benzer olması, çalışmamızdaki bitkiler arasında içerdikleri enzimler açısından istatistiksel olarak belirgin fark olmadığı bulgusu desteklenmktedir.

Bununla birlikte, elde edilen sonuçlar bu bitkilerin antidiabetik aktivitesinin tamamen eşdeğer olduğu anlamına gelmemektedir. Bitkilerdeki biyoaktif bileşiklerin ekstraksiyon yöntemi, çözücü tipi, fenolik konsantrasyon, mevsimsel değişim ve yetişme koşulları gibi faktörlere bağlı olarak değişebildiği bilinmektedir. Dolayısıyla daha büyük örneklem grupları, farklı ekstrakt tipleri ve saf bileşiklerin karşılaştırıldığı ileri analizlerle bitkiler arasındaki ince biyokimyasal farklılıkların daha net ortaya konulması mümkündür.

SONUÇ

Sonuç olarak, bu çalışma halk arasında antidiyabetik olarak bilinen altı bitkinin antidiyabetik potansiyelleri olan alfa-glukozidaz, amilaz, ketoheksokinaz, aldosereduktaz ve dipeptidil peptidazın (DPP4) enzim aktiviteleri açısından benzer etki düzeyine sahip olduğu göstermekte ve bu bitkilerin fonksiyonel gıda veya tamamlayıcı tedavi alanında ortak antidiyabetik etkiye sahip olabileceğini ortaya koymaktadır

TEŞEKKÜR

Bu çalışmanın planlanması ve yürütülmesi sürecindeki değerli akademik yönlendirmeleri için danışmanım Prof. Dr. Cevat Nisbet'e teşekkür ederim.

Abstract

Colorectal cancer refers to tumors of the colon or rectum that emerge from the abnormal expansion of glandular epithelial cells. Colorectal cancer is characterized by a complex molecular pathogenesis involving dysregulation of cellular stress responses, DNA damage pathways, and apoptosis. Bax, a pro-apoptotic member of the B-cell leukemia/lymphoma 2 protein (BCL-2) family, plays a critical regulatory role by promoting mitochondrial outer membrane permeabilization and initiating the intrinsic apoptotic cascade. Alterations in Bax expression have been associated with tumor progression, treatment response, and resistance mechanisms in previous studies. The aim of this study was to comparatively evaluate Bax gene expression in colorectal cancer tissues and adjacent non-tumorous tissues from the same individuals. Tumor tissues and matched adjacent healthy tissues were collected from 30 patients undergoing colorectal cancer surgery. Following tissue homogenization, total RNA was isolated, and cDNA synthesis was performed. Bax gene expression was quantified using real-time quantitative PCR with GAPDH as the internal reference gene. Ct values were analyzed using the $\Delta\Delta C_t$ method, and tumor–healthy paired samples were statistically compared. Fold-change values and related statistical analyses were calculated using appropriate methods. The analysis revealed no significant difference in Bax gene expression between tumor tissues and matched adjacent healthy tissues. Both ΔΔCt values indicated that Bax expression remained stable across paired samples. Fold-change analysis further confirmed the absence of a marked increase or decrease in Bax levels in tumor tissues. The lack of differential Bax expression between tumor and healthy tissues suggests that mitochondrial apoptotic signaling may not be significantly modulated through Bax in this patient cohort. Evaluating Bax together with additional apoptotic markers and expanding the sample size may provide a more comprehensive understanding of its role in colorectal cancer biology.

Keywords: Bax, colorectal cancer, qPCR, gene expression, apoptosis

Introduction

Colorectal cancer (CRC) is one of the most rapidly increasing malignancies worldwide and represents a major global health burden. According to data from the World Health Organization, CRC is among the most commonly diagnosed cancers in both men and women and remains one of the leading causes of cancer-related mortality despite significant advances in diagnosis and treatment [1]. Aging, dietary habits, obesity, sedentary lifestyle, genetic predisposition, and inflammatory bowel diseases are important factors contributing to CRC development. However, the presence of risk factors alone cannot fully explain the disease; tumor formation reflects a multistep pathological transformation that begins in normal colonic epithelial cells and progressively increases genomic instability [2]. The adenoma–carcinoma sequence, a well-established model of CRC pathogenesis, demonstrates that sequential genetic and epigenetic alterations drive cellular transformation. Mutations in tumor suppressor genes and oncogenes such as APC, KRAS, and p53, along with DNA methylation, histone modifications, and microsatellite instability, play critical roles in this process [2]. These molecular events lead to enhanced cellular proliferation, impaired DNA repair mechanisms, and the development of resistance to programmed cell death (apoptosis). In particular, disruption of apoptosis allows tumor cells with accumulated genomic damage to survive, contributing to one of the fundamental hallmarks of cancer: sustained proliferative capacity [3]. Apoptosis is a tightly regulated form of programmed cell death that enables the systematic elimination of cells in response to

physiological or pathological stimuli. It plays a vital role in maintaining tissue homeostasis and ensures the removal of cells that harbor unrecoverable genetic damage, oxidative stress, or severe DNA lesions. Failure or suppression of apoptotic pathways allows genetically unstable cells to continue proliferating, thereby promoting tumor initiation and progression [3]. Within this context, the Bcl-2 protein family serves as a central regulator in determining cell fate. The Bcl-2 family consists of both anti-apoptotic (Bcl-2, Bcl-xL, Mcl-1) and pro-apoptotic (Bax, Bak, Bid, Bad) proteins that control mitochondrial outer membrane permeability in the intrinsic apoptotic pathway [4]. Anti-apoptotic members protect the cell against death signals, whereas pro-apoptotic members initiate cell death. Bax (Bcl-2–associated X protein) is one of the key pro-apoptotic effectors responsible for mitochondrial outer membrane permeabilization, subsequent cytochrome-c release, and activation of the caspase cascade [5]. Bax exists in an inactive cytosolic form under physiological conditions; however, upon apoptotic stimulation, it undergoes conformational change, translocates to the mitochondria, oligomerizes, and initiates apoptosis [6].Downregulation of Bax expression, loss of protein function, or defects in transcriptional or translational regulation contribute significantly to the development of apoptosis resistance in CRC. Indeed, Bax gene mutations are frequently observed in microsatellite instability–high CRC cases, suggesting a link between Bax alterations and specific molecular subtypes of CRC [7]. Moreover, a reduced Bax/Bcl-2 ratio is associated with resistance to cell death signals, increased tumor aggressiveness, and poor therapeutic response. Since many chemotherapeutic agents exert their cytotoxic effects by inducing Bax-dependent apoptosis, alterations in Bax levels are closely associated with chemotherapy resistance [8]. Therefore, evaluating Bax expression in tumor tissues and comparing it with adjacent normal colonic tissues is crucial for understanding how apoptotic mechanisms are altered during CRC development. Identifying these differences not only contributes to elucidating the biological processes underlying tumorigenesis but also aids in the discovery of diagnostic and prognostic biomarkers. In addition, determining the expression levels of apoptosis-related proteins such as Bax may serve as a fundamental step toward developing personalized treatment strategies for CRC patients [9]. Particularly in chemoresistant CRC subtypes, monitoring Bax expression may provide clinically significant insights for treatment planning. In conclusion, investigating Bax expression in colorectal tumors and adjacent healthy tissues offers valuable information regarding the alterations in apoptotic pathways during cancer development. Such studies have the potential to enhance understanding of CRC biology, identify new therapeutic targets, and improve prognostic evaluation. Given the central role of apoptosis resistance in cancer progression, detailed examination of Bax in CRC carries substantial scientific and clinical importance [9].

Material and Method

Study population

In this study, both tumor tissue and surrounding healthy tissue samples were obtained during surgical resection from 30 patients diagnosed with colorectal cancer. Each patient was administered a detailed demographic and clinical information form, including age, gender, height, weight, body mass index (BMI), smoking status, alcohol consumption, presence of hypertension, presence of diabetes, history of hyperlipidemia, cardiovascular disease status, family history of cancer, and dietary habits. The study included patients diagnosed with colorectal cancer and scheduled for surgical treatment, those aged 18 years or older, and those who fully answered all questions on the patient information form. Patients who had previously received chemotherapy, radiotherapy, or immunotherapy, those in the metastatic stage who had not undergone surgery for the primary tumor, and those for whom a sufficient quantity or quality of tissue samples could not be obtained were excluded. This study was approved by the Sivas Cumhuriyet University Non-Interventional Clinical Research Ethics Committee (Decision No: 2025-07/78, Date: July 10, 2025). The purpose and scope of the study were explained to all participants, and written informed consent was obtained from each individual.

Tissue Homogenization

In order to obtain high-quality RNA from both tumor and adjacent healthy colon tissues, tissue homogenization was performed in accordance with standard molecular biology protocols. Tissue samples collected during surgery were immediately placed in RNA later solution to preserve RNA integrity and stored at -80°C until analysis. Approximately 30–50 mg of tissue was transferred to RNase-free tubes. Homogenization ensured that the samples

were suitable for RNA isolation; during this process, the samples were kept on ice and RNase-free conditions were maintained to prevent RNA degradation. The resulting homogenates were incubated briefly at room temperature to facilitate the dissociation of nucleoprotein complexes and were then prepared for subsequent RNA isolation.

RNA Isolation and cDNA Synthesis

Total RNA was isolated from homogenized tumor and healthy colon tissue samples using the FavorPrep™ Total RNA Isolation Kit II, following the manufacturer's protocol. All procedures were carried out under RNase-free conditions, with careful attention to preserving RNA integrity. The concentration and purity of the isolated RNA were measured, and only samples with an A260/A280 ratio between 1.8 and 2.1 were used. Complementary DNA (cDNA) was synthesized using the reverse transcription reagents provided in the OneScript Plus cDNA Synthesis Kit (abm), and the resulting cDNA was stored under appropriate conditions for subsequent gene expression analyses.

Gene Expression

PCR analysis was performed according to the protocols of the NucleoGene Biotechnology (Turkey) kit. Subsequently, BAX gene expression was assessed using quantitative RT-PCR (qPCR) in accordance with the kit instructions, with GAPDH serving as the internal reference gene.

Statistical analysis

SPSS Software (Version 22.0) was used for statistical analysis of the data in our study. PCR data were analyzed using Student's t-test, which tests the significance of the difference between two means. The error level was set at 0.05. Descriptive statistics are presented as mean ± SD or as n (%), where appropriate.

Results

Demographic Characteristics

Colorectal cancer tissue and surrounding healthy colon tissue were surgically removed from 30 patients with colorectal cancer included in the study. A questionnaire was administered to the patients. Statistical analysis of the questionnaire data revealed that 46.7% of the total population was female and 53.3% male. Alcohol consumption was assessed as 16.7% of the individuals consuming alcohol, while 83.3% did not. 43.3% of the individuals were smokers, and 53.3% were non-smokers. Clinical data indicated that 46.7% of the individuals had hypertension and 26.7% had diabetes. Hyperlidemia was also observed in 16.7% of the individuals, and cardiovascular disease was observed in 30.0%. 46.7% of the patients had a family history of cancer. Additionally, the patients' dietary habits were examined, and it was found that 13.3% of them had a balanced diet, 26.7% a meat-based diet, 23.3% a pastry-based diet, and 36.7% a fruit and vegetable-based diet (Table 1).

Tablo 1. Clinical and demographic information of individuals from whom colorectal cancer and adjacent healthy tissues were collected

	N (%)
Gender	
Female	14 (46.7)
Male	16 (53.3)
Alcohol	
Consuming	5 (16.7)
Non-consuming	25 (83.3)
Smoking	
Smoker	13 (43.3)
Non-smoker	16 (53.3)
Hypertension status	
Hypertensive	14 (46.7)
Non-hypertensive	16 (53.3)
Presence of Diabetes	
Yes	8 (26.7)
No	22 (73.3)
History of Hyperlipidemia	
Yes	5 (16.7)
No	25 (83.3)
Cardiovascular Disease	
Yes	9 (30.0)
No	21 (70.0)
Cancer History	
Yes	14 (46.7)
No	16 (53.3)
Dietary Habits	
Balanced diet	4 (13.3)
Meat-based diet	8 (26.7)
High-pastry	7 (23.3)
Fruit and vegetable based diet	11 (36.7)

When the gender-based evaluation was made, the mean and standard deviation were taken into account, and the female age was recorded as 57.36 ± 9.44, height was 160.43 ± 8.39, weight was 71.64 ± 15.93, and BMI was 27.89 ± 6.30. The male age was noted as 58.44 ± 10.64, height was 171.75 ± 8.68, weight was 74.25 ± 13.13, and BMI was 26.62 ± 4.49 (Table 2).

Tablo 2. Gender based comparison of anthropometric measures

Gender	Characteristics	Mean±Std. Deviation
Female	Age	57.36 ± 9.44
	Height	160.43 ± 8.39
	Weight	71.64 ± 15.93
	BMI	27.89 ± 6.30
Male	Age	58.44 ± 10.64
	Height	171.75 ± 8.68
	Weight	74.25 ± 13.13
	BMI	26.62 ± 4.49

qPCR analysis

Bax gene expression levels were measured in colon cancer and compared to surrounding healthy tissues. The data revealed a 1.92-fold increase in Bax gene expression in colon cancer tissues compared to surrounding healthy colon tissues, but this increase was not significant ($p<0.05$) (Figure 1).

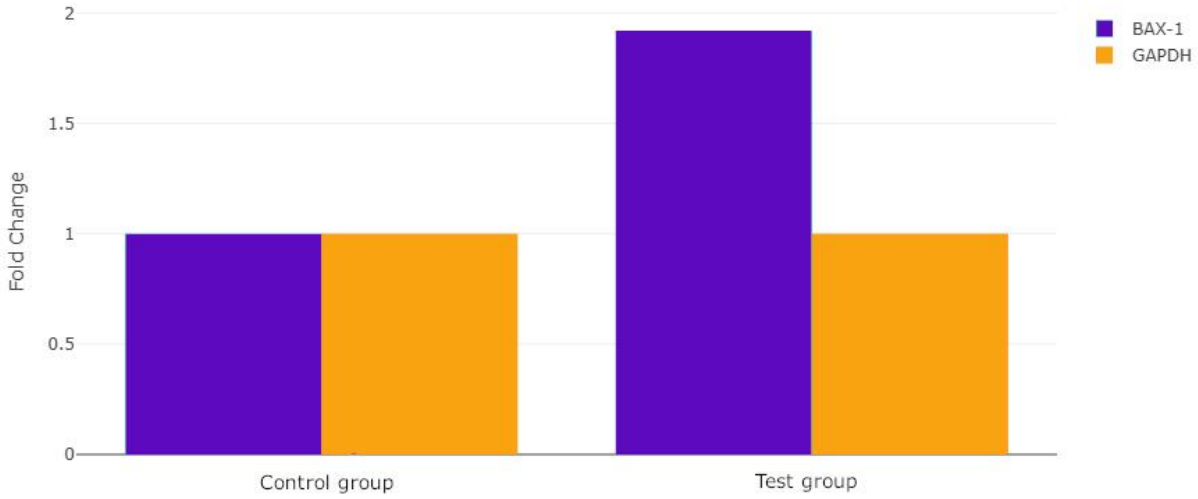

Figure 1. Fold change graph of Bax-1 expression in colon cancer tissues (test group) and healthy surrounding colon tissues (control group)

Discussion

In this study, we looked at BAX gene expression in colorectal cancer (CRC) tissues and nearby non-tumor tissues. We found no significant difference between the two groups. BAX, a key pro-apoptotic member of the BCL-2 family, is expected to decrease in tumors that have developed resistance to apoptosis. However, our findings show that BAX expression in CRC is not consistently changed, which is in line with previous research indicating considerable variability in apoptotic regulation among patients. Several studies have noted increased BAX expression during the adenoma-carcinoma sequence. Cobanoglu et al. observed that BAX immunoreactivity increases from normal mucosa to adenoma and carcinoma stages, suggesting that high BAX levels may accompany early tumor transformation [10]. In contrast, Jansson and Sun found a significant drop in BAX expression from primary tumors to metastatic lesions, indicating that the loss of BAX might help late-stage progression [11]. This difference reflects the biological variety of CRC and suggests that BAX dysregulation may depend on tumor stage, histological grade, genetic background, or microenvironmental factors. Lower BAX levels have also been linked to aggressive tumor features. Studies show that low BAX expression is associated with lymphovascular invasion, deeper tumor infiltration, and shorter overall survival [12, 13]. Sturm et al. further reported that low BAX expression, especially in the presence of p53 mutations, predicts worse outcomes in patients with removed liver metastases [14]. These findings support the idea that impaired pro-apoptotic signaling contributes to tumor growth and resistance to treatment. On the other hand, several studies found no significant link between BAX levels and significant clinicopathological variables. Khodapasand et al. reported that BAX or BCL-2 did not correlate with tumor stage or grade, while the BAX/BCL-2 ratio offered more relevant prognostic information [15]. This ratio reflects the balance between pro- and anti-apoptotic factors and is seen as a better marker of apoptotic sensitivity. From this view, unchanged BAX expression in our study might indicate increases in anti-apoptotic molecules like BCL-2 or BCL-xL, or issues with BAX activation instead of its transcription. Additionally, apoptotic regulation in CRC goes beyond just BAX transcription. Factors like mitochondrial priming, BAX movement to mitochondria, post-translational modifications, and p53 functionality significantly affect apoptosis [16, 17]. Wild-type p53 directly activates BAX to induce mitochondrial outer membrane permeabilization, but in p53-mutant CRC, BAX cannot be activated effectively even if its expression stays stable [18, 19]. Therefore, tumors may show unchanged or even higher BAX levels while still resisting apoptosis. Moreover, the tumor microenvironment—including hypoxia, cytokines, inflammatory factors, stromal interactions, and immune infiltration—affects apoptotic pathways independently of BAX [20, 21]. Overall, our findings support the growing view that BAX alone is not enough as a biomarker for CRC diagnosis, prognosis, or predicting treatment response. A multi-parameter approach that includes BAX, BCL-2 family proteins, p53 mutation status, caspase activation, and mitochondrial apoptotic signaling offers a better understanding of tumor biology [22]. Future studies should use multi-omic strategies that combine transcriptomics, proteomics, and functional apoptotic tests to better characterize the apoptotic landscape of CRC [23].

Conclusion

In conclusion, while BAX has a key role in intrinsic apoptosis, its expression shows considerable variability in colorectal cancer. The lack of significant differences between tumor and nearby healthy tissues in our study aligns with findings that apoptotic dysregulation in CRC stems from a complex network rather than just isolated changes in BAX. A thorough evaluation of apoptosis-related mechanisms may help improve biomarker discovery and tailored treatment strategies.

Abstract

Parkinson's disease ranks second among the most prevalent chronic neurodegenerative diseases worldwide and grows faster than other neurodegenerative diseases. Notably, there are only symptomatic treatments available for patients with Parkinson's disease, which is dopaminergic replacement therapy, and no disease-modifying treatments are currently available. Moreover, the therapeutic effectiveness of many central nervous system drugs, including levodopa, is reduced by the restrictive nature of the blood–brain barrier, which prevents sufficient penetration into neural tissues. However, due to their small size and high surface area-to-volume ratio, nanoparticles can cross the blood–brain barrier, thereby providing benefits for the treatment of neurodegenerative diseases, including Parkinson's disease, by increasing drug delivery across the blood–brain barrier. Over the years, some phytochemicals from natural sources have provided a valuable resource for identifying potential therapeutic compounds for Parkinson's disease treatment, due to their anti-inflammatory and antioxidant properties. Recently, nanotechnology has emerged to address the drawbacks of these phytochemicals, including their poor bioavailability, poor stability under physiological conditions, and limited prolonged impact. Furthermore, after ingestion, nanoparticles initially interact with the gastrointestinal epithelium and the gut microbiota, which, through the gut–brain axis, may play a role in the initiation and progression of neurodegenerative diseases. Given that people with Parkinson's disease's dietary habits influence their gut microbiome, it is crucial to consider nutrition when implementing strategies combining phytochemicals and nanoparticles for Parkinson's disease treatment. In addition, among people living with Parkinson's disease, the awareness regarding the use of nanoparticles in the treatment of Parkinson's disease is relatively low. Therefore, our chapter aims to gather up-to-date data to explore a potential treatment strategy for Parkinson's disease and encourage future research endeavors.

Keywords: Nanotechnology, medicinal and aromatic plants, Parkinson's disease, biogenic nanoparticles, phytochemicals, nutritional intervention

INTRODUCTION

Neurodegenerative diseases (NDs) are a variety of complex diseases that are characterized by neuronal loss and progressive degeneration of various parts of the nervous system (Agnello & Ciaccio, 2022). Parkinson's disease (PD) ranks second among the most prevalent chronic NDs worldwide and grows faster than other NDs (Pirovano et al., 2025). Neural inclusions, including Lewy bodies and Lewy neurites, along with cell loss in the substantia nigra and other parts of the brain, are the hallmarks of PD pathology. Since Lewy bodies are composed mostly of aggregated and misfolded α-synuclein, PD is categorized as a synucleinopathy (Tolosa et al., 2021). Notably, there are only symptomatic treatments available for patients with PD, which is dopaminergic replacement therapy, and no disease-modifying treatments are currently available (Pirovano et al., 2025). Moreover, the therapeutic effectiveness of many central nervous system drugs, including levodopa, is reduced by the restrictive nature of the blood–brain barrier, which prevents sufficient penetration into neural tissues (Gao et al., 2025). However, due to their small size and high surface area-to-volume ratio, nanoparticles (NPs) can cross the blood–brain barrier

(BBB), thereby providing benefits for the treatment of NDs, including PD, by increasing drug delivery across the BBB (Li et al., 2025; Hassan et al., 2025; Gao et al., 2025). Over the years, some phytochemicals from natural sources have provided a valuable resource for identifying potential therapeutic compounds for PD treatment, due to their anti-inflammatory and antioxidant properties (Doke et al., 2019). Polyphenols' clinical utilization is hindered by their poor distribution in the human body, despite having medicinal properties (Sardarabadi et al., 2024). PD symptom severity and disease progression are influenced by diet quality through various mechanisms, including its effect on gut microbiome composition (Baghaei et al., 2025). Recently, nanotechnology has emerged to address the drawbacks of these phytochemicals, including their poor bioavailability, poor stability under physiological conditions, and limited prolonged impact (Paul et al., 2023). Furthermore, after ingestion, NPs initially interact with the gastrointestinal epithelium and the gut microbiota (GM), which, through the gut–brain axis, may play a role in the initiation and progression of NDs (Li et al., 2025). Therefore, our chapter aims to gather up-to-date data to explore a potential treatment strategy for Parkinson's disease and encourage future research endeavors.

LITERATURE ON PARKINSON'S DISEASE, PHYTOCHEMICALS, AND NANOTECH-NOLOGY

The pathogenesis of PD is correlated with different factors such as gut dysbiosis, increased oxidative stress, neuroinflammation, and mitochondrial dysfunction (Grancharova et al., 2024). Phytochemicals (e.g., polyphenols, carotenoids, flavonoids, and terpenoids) have been found to modulate the GM, as well as implement neuroprotective, anti-inflammatory, and antioxidant effects, which could benefit the management and prevention of neurological conditions (Jaberi et al., 2024). Diet plays a key role in modulating the GM composition, and various dietary patterns can cause specific bacteria to be less or more abundant. Consequently, changes in the abundance of the microorganisms can influence gut permeability and produce anti-inflammatory or pro-inflammatory metabolites. Plant-based diets have been shown to diminish inflammation and oxidative stress, which are two important factors related to NDs, including PD. Therefore, a healthy diet rich in nutrients with antioxidants and anti-inflammatory properties may play a crucial role in preventing the risk of Parkinsonism. The Mediterranean Diet (MeDiet) is a rich dietary pattern in terms of antioxidants and anti-inflammatory agents (Bisaglia, 2023). In addition to the MedDiet, the MIND (Mediterranean-DASH Diet Intervention for Neurodegenerative Delay) and DASH diets are also plant-based diets focusing on vegetables and fruits, legumes, nuts, whole grains, poultry, fish, and low intake of saturated fats as well as red meats (Agarwal et al., 2018).

NPs are described as particles that have a diameter of 10 – 1000 nanometers (Elikaee et al., 2025). There are several techniques for NP synthesis, and among them, green synthesis has gained popularity due to its simplicity and therapeutic potential. Green synthesis is done with natural and environmentally friendly compounds, including plant extracts in order to reduce metal ions and create NPs. Additionally, bioactive plant compounds on the surface of NPs enhance their therapeutic effectiveness. Recently, metal ions that mimic enzyme activities have been increasingly utilized in various nanoparticle applications (Grancharova et al., 2024). For example, gold NPs (AuNPs) functionally mimic endogenous antioxidant enzymes and may diminish oxidative stress. They demonstrate activities like superoxide dismutase by eliminating O_2, exhibit catalase-like functions by converting H_2O_2 into water and oxygen, and show peroxidase activity by catalyzing oxidation reactions of peroxides and such molecules (Grancharova et al., 2024). Additionally, AuNPs have been demonstrated to convert NADH to NAD+, which plays a crucial role in cellular energy production (Huang et al., 2005; Grancharova et al., 2024). In a Drosophila melanogaster rotenone-induced preclinical model, the administration of green-synthesized ZnO NPs significantly reduced oxidative stress, likely due to their antioxidant effects and the restoration of endogenous antioxidant defence enzymes (Shabir et al., 2023).

Nanotechnology is becoming increasingly important in the food and pharmaceutical industries. For instance, nanoemulsions are used with herbal extracts, and others incorporate oils into food products. Nano-herbal formulations are the primary focus, which enhance the efficiency and delivery potential of therapeutic agents through nanotechnology (Shree et al., 2025). It promotes the integration of traditional herbal medicine with technology, focusing on the nutritional quality and functionality of nanoherbal formulations in the food industry (Awlqadr et al., 2025). Nanoherbal drugs may provide several benefits, but safety concerns remain significant. Due to their small size, they can react differently in the human body. Thus, thorough testing is essential (Farhang et al., 2025).

CONCLUSION

PD is a growing global health problem that affects the geriatric population more than others. Hence, it is crucial to explore promising symptomatic or, if possible, curative treatment options for PD to ameliorate the quality of life in people with PD. To our knowledge, research demonstrating a symptomatic or curative treatment option for PD via gut-mediated, food-based biogenic nanotechnology utilizing phytochemicals is lacking. In addition, among people living with PD, the awareness regarding the use of nanoparticles in the treatment of PD is relatively low. Since GM plays a role in PD development and an NP initially interacts with gut epithelium, this interaction may be used to enhance the bioavailability of phytochemicals, such as curcumin, and enable them to demonstrate their antioxidant and neuroprotective effects more effectively. Therefore, as preclinical research is more abundant than clinical human trials, more research is needed in this area to elucidate the relationship between food-phytochemical-nanoparticle combined therapies for PD.

ORAL PRESENTATION

Impair DNA Methyltransferases Gene DNMT1 Level and Alternated Immune Agents in Systemic Lupus Erythematosus of Iraqi Patients

Atheer Ahmed

University of Baghdad, Iraq

Abstract

New research results have revealed a worldwide decline in gene DNA methylation (*DNMT1*), resulting in reduced transcription-level expression of CD4 + T cells. This phenomenon is directly related to the development of systemic lupus erythematosus (SLE). The research also has investigated the impairing between total DNA methylation and DNA activity (cytosine-5) methyltransferase. 1 (DNMT1), which it does main role in the process of DNA methylation. It has showed significant chang and reduction in *DNMT1* gene expression in PBMC for SLE patients. To measure this, real-time polymerase chain reaction (RT-PCR) was used to identify the entire genome and purified peripheral mononuclear blood cells (PBMC) in both individuals with systemic lupus erythematosus (SLE) and healthy individuals. It has showed significant reduction in *DNMT1* gene expression in PBMC for SLE patients. Consequently, appearance results singed for, the expression of IL-4 transcript in SLE patients was significantly decreased compared to that in healthy controls. The indirect impact of an underlying DNA hypomethylation status on patients' response can be considered plausible. This impact may involve the inhibition of mRNA levels of DNA methyltransferases, especially during periods of significant disease activity. Consequently, it can lead to changes in various immune components, including increased levels of IgM. Autoimmune diseases may be caused with DNA methylation disfunctions in various cell types that it have included SLE disease ,it maybe the differentiation and developmental events in genomic patterns of methylation and the immune responses that become dysregulated in specific autoimmune diseases.

Keywords: Systemic lupus erythematosus, DNA methyltransferase. IL-4, IgM

Key messages: Systemic lupus erythematosus (SLE) is a systemic autoimmune disease with multisystem involvement and is associated with chang of morbidity and mortality involved maltreated genetic, immunological, endocrine, and environmental factors

Introduction :

DNA hypomethylation seems to assume a significant role in related to the pathogenesis of SLE. which have been reported to be a plausible causative agent for systemic lupus erythematosus (SLE) [1] .
SLE is a complex autoimmune disease characterized by apoptosis cell surrender, a signature of interferon expression (IFN) of PBMC have made marker for breakdown of peripheral tolerance mechanisms responsible to generate autoantibodies attach tissues and organs damage [2,3]. T cells play a key role in causing SLE, amplifying inflammation by secreting pro-inflammatory cytokines, helping B cells generate autoantibodies, and maintaining the disease through the accumulation of self-reactive memory T cells [4,5].

Patients with (SLE) often experience various clinical manifestations, commonly linked to tissue damage resulting from the accumulation of antibodies and autoimmune complexes [6,7]. These deposits contribute to the observed skin, mucous membrane, kidney, joint, nervous system, lung, and heart lesions. There is a strong belief that disease-related factors interact with genomic and epigenomic processes.
Epigenomic mechanisms, including identifiable DNA methylation patterns, play a vital role [8,9], This implies that cells possess the ability to modify their methylation through methyltransferases. In SLE patients, these mechanisms may significantly impact the hypomethylation function of *DNMT* cluster genes. This impact is associated with certain pathological aspects and abnormal histone modifications, leading to the suppression of gene transcription responsible for initiating and perpetuating pro-inflammatory responses, particularly within their

CD4+ T cells [10,11]. In individuals with systemic lupus erythematosus (SLE), the activity of the *DNMT1* gene, which plays a role in regulating methylation, has been found to be reduced in peripheral blood mononuclear cells (PBMC) be compared with healthy control subjects. [12,13].

This abnormal methylation pattern may pose a risk for certain autoimmune conditions, particularly affecting women of reproductive age. The disrupted methylation observed in SLE development is believed to stem from a breakdown in immunological tolerance and the interplay between susceptibility genes for SLE and diverse environmental factors, ultimately leading to the generation of harmful autoantibodies [14,15].

However, the *DNMT1* gene is situated within replication foci and consistently operates during cell division through various mechanisms. It functions both as a maintenance enzyme crucial for preserving the stability of existing DNA methylation patterns and as a vital cofactor for de novo methyltransferase in Embryonic stem cells [16,17].

The study's aim:

The research demonstrated its collaborative role in identifying key immune factors linked to hypomethylation, particularly in SLE Iraqi patients with a malfunctioning *DNMT1* gene expression. Furthermore, investigations focused on the behaviour of IL-4 and IgM, pinpointing SLE risk variants, have the potential to enhance the arsenal of prognostic and therapeutic biomarkers for SLE (18,19).

Methods:

Patients with (SLE) were diagnosed by clinical symptoms and screening markers (Anti-double-stranded DNA, C3, C4, Antinuclear Antibody ANA) and LN (approved by biopsy) for 15 male, 45 female and 60 healthy male and female (control) in medical city hospital in Baghdad. All patients under treatment daily doses 7.5 mg of prednisone. (PBMCs) were isolated from Iraqi SLE patients and healthy controls. DNA extraction use (Quick-DNA™ Blood MiniPrep Catalog) . Reverse transcription and real-time quantitative polymerase chain reaction (RT-qPCR) analyzes RNA extraction (Direct-zol™ RNA MiniPrep, R2051, ZYMO RESEARCH/USA.) were used to determine DNMT1 and IL-4 mRNA expression level in Cycling Program (Enzyme activation 95 °C, Denaturation 95 °C, annealing 60.0 °C, Extension72.0 °C) holed 40 cycles (figure.1). IgM level marker for SLE therapeutic detection was used radial immunodiffusion plate,

Results and discussion:

1- Exclusion criteria and SLE biomarkers:

This variable concentration of hormones, genetic defection environmental conditions and different populations under different conditions involving menstrual cycling, chronic stress, corticosteroid medication, oral contraceptives and the replacement of steroid hormones a protein which is virtually absent from a healthy person's serum. they have participated for lack of self-tolerance has contributed to autoantibody production, pro-inflammatory and cytokine inflammatory. Significantly, last autoimmunity responses were surely caused Global methylation up regulation [20].

Extremely, samples have be obtained from hundred subjects for both genders were enrolled some of in this study, who attended Baghdad Teaching Hospital/Medical City Iraq. The subjects were involved on group consists of patients suffering SLE male and female aged (16-46) years and group consists of healthy individual's male and female at age (19-47) years (control group) [21]. The patients have Systemic lupus erythematosus were diagnosed by clinical symptoms and screening markers (Anti-double-stranded DNA, Antinuclear Antibody ANA, C3, C4). All patients under treatment daily doses 7.5 mg of prednisone.

2- *DNMT1* gene

Human genetic variations in the background lead to immunodeficiency. *DNMT1* exhibits a preference for hemimethylated DNA as its substrate, methylating newly replicated DNA only when the template nucleotides are already methylated [22,23]. *DNMT1* is consistently expressed and plays a crucial role in preserving overall methylation levels after DNA replication. These findings indicate the existence of distinct epigenetic Susceptibility sites that predispose to or are associated with skin manifestations in SLE. These loci demonstrate significantly higher methylation levels compared to those in healthy controls. Moreover, SLE patients display a notable reduction in *DNMT1* transcript levels, ranging from a 5.9 to 2.7-fold decrease as observed (Figure. 2).

3- ***IL-4*** **transcripted level**

Defected *DNMT1* transcript level is one mechanism involved is the aberrant activation of certain Th2 cell subsets, such as CD4+ T cells, and the expression of specific molecules on their surface, including CD38 [24,25]. CD4+ T cells and abnormalities in CD38 are a subset of Th2 cells that play a crucial role in regulating immune responses and contribute to the pathogenesis of SLE by producing various cytokines. last defects can disrupt normal cellular functions, including Th2 cell activation and cytokine production. One cytokine that has been deregulated in SLE pathogenesis is interleukin-4 (IL-4) (26,27,28).

The findings indicate a change in the levels of IL-4 transcripts from a 4.2 to 1.07-fold decrease as determined with competitive PCR assay. This shortage was observed in the SLE group, as shown in (Figure 2).

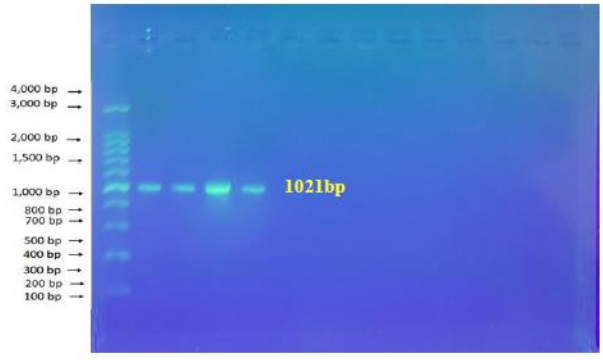

Figure (1): Gel electrophoresis *Dnmt1* gene 1021bp in peripheral blood mononuclear cells (PBMC) of SLE patients .1% agarose gel

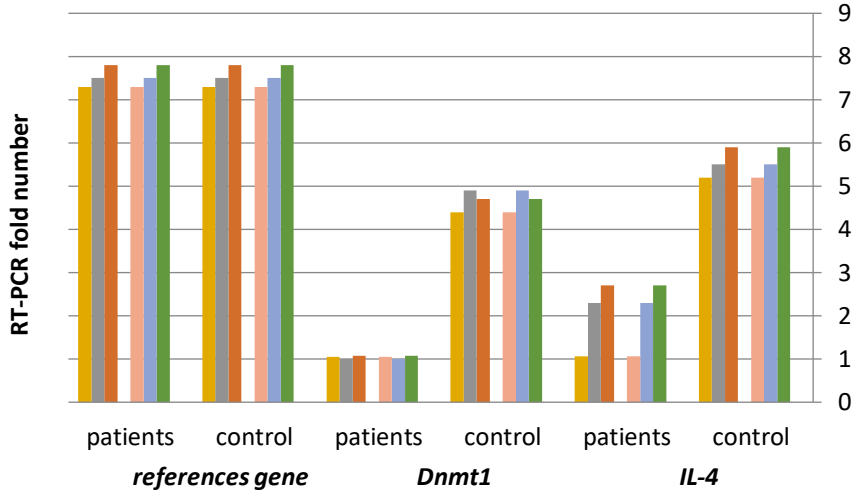

Figure (2): Quantitative analysis of *Dnmt1* and *IL-4* expression in PBMC from healthy adults (control) and SLE patients. The results represent the lower number of genes cDNA molecules comprated with references gene

4- IgM level in SLE disease:

IL-4, a significant cytokine, plays a crucial role in promoting B-cell differentiation. Blocking IL-4 has been shown to prevent this process. Research conducted on patients with systemic lupus erythematosus (SLE) suggests that there is a breakdown in the regulatory mechanisms of B cells at both the central Bone marrow checkpoints and terminal checkpoints during the naïve transition B cell stage. Moreover, individuals with SLE exhibit impaired function of naive B cells, indicating a reduced activity level [28, 29, 34].

The IL-4 transgene appears to have a beneficial effect, likely achieved by defected regulating of Th2 responses involved in autoantibody production in our SLE patient model. However, this down-regulation doesn't affect IgM antibody responses to T cell–independent antigens or auto-IgG [30,31] , as evidenced by the lack of significant impact on serum levels of IgM antibodies. Interestingly, the results show a rise in IgM activity on erythrocyte surfaces do anti- IgG (Figure 3), despite this.

In SLE, human lupus serums exhibit two distinct sets of IgM antibodies. Remarkably, the presence of an IgM reaction on the surfaces of red blood cells in the patient's serum is associated with a decrease in the severity of the disease [32,33,34] representing a potential therapeutic biomarker.

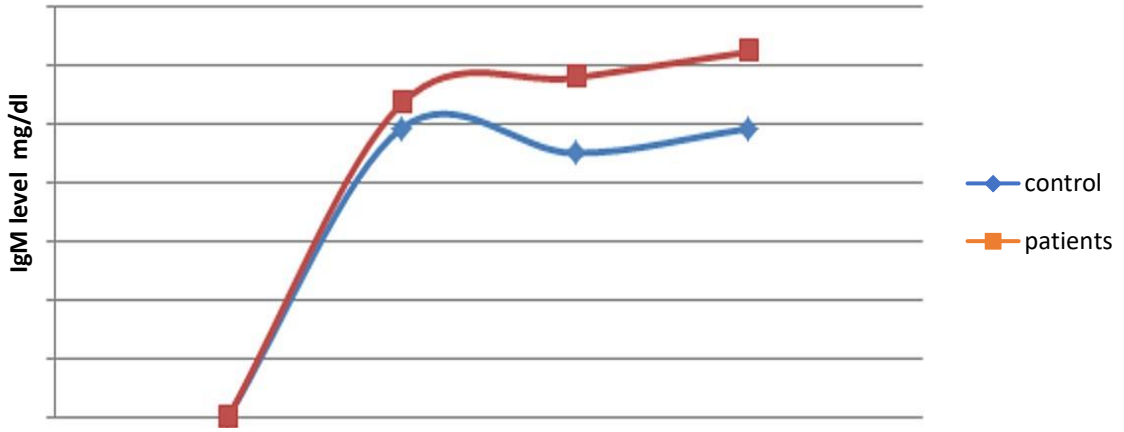

Figure (3) : IgM level in SLE disease

Conclusion:

DNA methylation is a key mechanism for epigenetic modifications, and we will focus on its detection. Specifically, we'll pay attention to how DNA methylation functions in various cell types associated with autoimmune diseases, the genomic patterns of methylation involved in differentiation and developmental events, and the immune responses that become dysregulated in specific autoimmune diseases. Additionally, It may be would explore the possibility of addressing whether IgM-induced immune deviation can offer protection against ongoing disease. Understanding this could pave the way for developing novel therapeutic approaches for managing SLE and other related human autoimmune diseases.

Ethical approval

The ethics committee of the Department of Biology - Collage of sciences – University of Baghdad gave its approval to this study before it began. Every patient was asked to provide their informed consent, approved by in medical city hospital in Baghdad**.**

Acknowledge

My profound thanks and appreciation to Dr.Noor Al-huda Khaleel for his support and assistance in Department of basic sciences – Collage of Nursing – University of Baghdad**.**

Özet

Triptofanın indol yapısını içeren valil-triptofan (Val-Trp) dipeptidleri, iyi bilinen biyoaktivitesi ve uygun çözünürlüğü, geçirgenliği ve biyoyararlanımı nedeniyle potansiyel antikanser ajanları olarak dikkat çekmektedir. Bu çalışmada, 24 ve 48 saatlik inkübasyondan sonra MTT testi kullanarak Val-Trp'nin insan meme kanseri MCF-7 hücreleri üzerindeki sitotoksik etkilerini araştırılmıştır. 1 mg/ml Val-Trp uygulanmış MCF-7 hücrelerinde 24 saatte %98 canlılık sağlarken, 48 saatte %52'ye belirgin bir düşüşe neden olmuştur. Bu bulgular, Val-Trp'nin MCF-7 hücreleri üzerinde zamana ve konsantrasyona bağlı sitotoksik etki gösterdiğini ve belirgin canlılık kaybının yalnızca en yüksek konsantrasyonda ve uzun süreli maruziyette gözlendiğini göstermektedir. Genel olarak, veriler Val-Trp'nin, özellikle meme kanseri hücre modelleri bağlamında, daha fazla antikanser değerlendirmesi için umut verici bir indol bazlı dipeptit iskeleti olarak potansiyelini desteklemektedir.

Anahtar Kelimeler: Valiltriptofan (Val-Trp), Dipeptit, Sitotoksisite, Antikanser

Investigation of the Cytotoxic Effect of the Val-Trp Dipeptide on MCF-7 Breast Cancer Cells

Abstract

Valyl-tryptophan (Val-Trp) dipeptides, which contain the indole structure of tryptophan, are attracting significant attention as potential anticancer agents due to their well-known bioactivity and favorable solubility, permeability, and bioavailability. In this study, the cytotoxic effects of Val-Trp on human breast cancer MCF-7 cells were investigated using the MTT assay after 24 and 48 hours of incubation. In MCF-7 cells treated with 1 mg/ml Val-Trp, cell viability was 98% at 24 hours, whereas a marked decrease to 52% was observed at 48 hours. These findings indicate that Val-Trp exerts time- and concentration-dependent cytotoxic effects on MCF-7 cells, and that a pronounced loss of viability is observed only at the highest concentration and with prolonged exposure. Overall, the data support the potential of Val-Trp as a promising indole-based dipeptide scaffold for further anticancer evaluation, particularly in the context of breast cancer cell models.

Keywords: Valyl-tryptophan (Val-Trp), Dipeptide, Cytotoxicty, Anticancer.

GİRİŞ

Triptofanın indol yapısını içeren valil-triptofan (Val-Trp) dipeptitleri, tıpta yaygın olarak kullanılan indol türevlerinin bilinen biyoaktivitesi nedeniyle, potansiyel antikanser etkileri açısından dikkat çekmektedir (Küçükbay ve ark., 2024). Yüksek çözünürlük, hücre zarından geçebilme ve biyoyararlanıma sahip bu dipeptitler, hücre yüzeyindeki reseptörlerle etkileşerek veya hücre içi sinyal ve düzenleyici yolaklara katılarak, terapötik etkilerini ortaya koymaktadır (Huang ve ark., 2017). Bu biyoyararlanım ve stabilite avantajları, Val-Trp gibi dipeptitlerin vücut içinde daha az parçalanmasını sağlar ve bu molekülleri hedefe yönelik tedaviler için daha uygun adaylar haline getirmektedir. Günümüzde, apoptoz indüksiyonu, mikrotübül bozulması ve anjiyogenez inhibisyonu gibi farklı mekanizmaları hedefleyen, daha az toksik ve maliyet açısından daha uygun yeni antikanser tedavilere duyulan ihtiyaç giderek artmaktadır. Bu bağlamda, peptitler, yeni terapötik yaklaşımlar geliştirilmesi için umut verici bir seçenek olarak öne çıkmaktadır. (González-Montoya, 2017).

Esansiyel bir amino asit ve çok sayıda doğal bileşiğin temel bileşeni olan triptofanın içsel biyolojik aktivitesi, Val-Trp dipeptitlerinin terapötik potansiyelini daha da artırmaktadır (Küçükbay ve ark., 2024). Özellikle, bu dipeptitler içindeki triptofan kalıntısının, Trp-Leu gibi diğer triptofan içeren dipeptitlerde gözlendiği üzere, anjiyojenik yolakların inhibisyonuna katkıda bulunduğu bildirilmiştir (Bose ve ark., 2022). Nitekim, çeşitli peptit-indol konjugatları, MCF-7 ve A549 gibi hücre hatlarında kayda değer antikanser aktiviteler göstermiş ve bu durum, indol grubunun farmakolojik profillere katkısını vurgulamıştır (Küçükbay ve ark., 2024). Ayrıca, valin gibi bir amino asidin triptofanın indol iskeletiyle birleştirilmesinin kanser hücrelerine karşı sitotoksisiteyi artırabildiği, bunun da sinerjistik etkilere işaret ettiği ileri sürülmektedir (Küçükbay ve ark., 2024). Bu artmış etkinlik, çoğu zaman, küçük hücreli akciğer karsinomu gibi hücre hatlarında sitotoksisiteyi anlamlı ölçüde iyileştirebilen indol halkasındaki çeşitli modifikasyonlara bağlanmaktadır (Offerman ve ark., 2017). Ayrıca peptitler; antimikrobiyal, antiinflamatuvar, antiviral ve antikanser özellikleri kapsayan geniş biyolojik aktivitelere sahip son derece işlevsel biyomoleküller olarak kabul edilmektedir (Borse ve ark., 2023). Bu geniş biyolojik etki yelpazesi, özellikle enzim inhibitörü ve ilaç taşıyıcısı olarak üstlendikleri roller nedeniyle, peptitleri ilaç keşfi açısından son derece cazip moleküller haline getirmektedir (Huang ve ark., 2017). Dipeptit-konjuge bileşiklerin, çeşitli insan kanser hücre tiplerine karşı yüksek in vitro etkinlik gösterdiği bildirilmiş olup, bu durum onların stabil ve etkili terapötik ajan adayları olarak öne çıkmasını sağlamaktadır (Borse ve ark., 2023). Bu stabilite, hücre zarını geçebilme kapasiteleriyle birlikte değerlendirildiğinde, dipeptitler hem hedeflenmiş ilaç taşıma sistemlerinde hem de onkolojide doğrudan terapötik ajan olarak kullanılabilecek umut verici adaylar olarak görülmektedir (Borse ve ark., 2023; Naglah ve ark., 2021).

Meme kanseri, dünya genelinde kadınlarda en sık görülen kanser tiplerinden biri olup, güncel tedavi seçeneklerine rağmen ilaç direnci, yan etkiler ve nüks gibi sorunlar yeni ve daha güvenli antikanser ajanların geliştirilmesini zorunlu kılmaktadır. İndol içeren dipeptitlerin antikanser potansiyeli çeşitli hücre hatlarında gösterilmiş olsa da, Val-Trp dipeptidinin MCF-7 meme kanseri hücreleri üzerindeki konsantrasyon ile zamana bağlı sitotoksik etkileri yeterince aydınlatılmamıştır. Bu çalışmada, Val-Trp'nin MCF-7 hücreleri üzerindeki etkilerini 24 ve 48 saatlik inkübasyon sürelerinde değerlendirilmesi ve buna bağlı olarak Val-Trp'nin indol bazlı bir antikanser molekülü olarak potansiyelinin ortaya koyulması amaçlanmıştır.

MATERYAL VE METOT

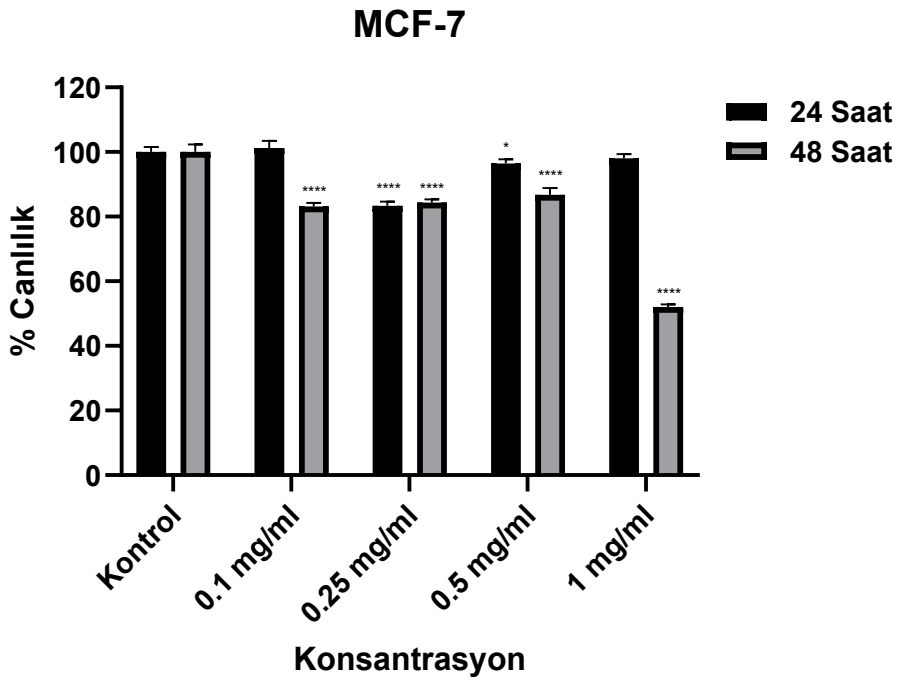
Hücre Hattı ve Kültür Koşulları

Bu çalışmada, insan meme adenokarsinom hücre hattı olan MCF-7 hücreleri kullanılmıştır. Hücreler, %10 fetal bovin serum (FBS) ve %1 penisilin/streptomisin içeren yüksek glikozlu DMEM besiyerinde, 37 °C'de, %5 CO_2 içeren nemlendirilmiş inkübatörde rutin olarak kültüre edilmiştir.

MTT Hücre Canlılığı Testi

Val-Trp dipeptidinin sitotoksik etkilerini değerlendirmek amacıyla MTT hücre canlılığı testi uygulanmıştır. Bu deney için MCF-7 hücreleri 96 kuyucuklu plaklara, 10^4/kuyucuk olacak şekilde ekilerek 24 saat inkübe edilmiştir. Val-Trp, stok konsantrasyonu 50 mg/ml olacak şekilde serumsuz besiyeri ile çözülmüştür. Hücreler, 0.1, 0.25 ve 1 mg/ml konsantrasyonlarında Val-Trp ile muamele edilerek 24 ve 48 saat süreyle inkübasyona bırakılmıştır. İnkübasyon sürelerinin sonunda, 20 µl MTT çözeltisi ilave edilerek, formazan kristallerinin oluşması için inkübe edilmiştir. Oluşan formazan kristalleri DMSO ile çözdürülmüş, absorbans değerleri mikroplaka okuyucu ile 570 nm dalga boyunda ölçülmüştür. Hücre canlılığı, kontrol grubuna göre yüzde (%) oranında hesaplanmıştır.

İstatistiksel Analiz



Elde edilen veriler, istatistiksel olarak iki yönlü varyans analizi (two-way ANOVA) ve post-hoc Tukey testi ile değerlendirilmiştir. Tüm sonuçlar ortalama ± standart sapma (SS) olarak ifade edilmiş ve $p < 0.05$ değeri istatistiksel olarak anlamlı kabul edilmiştir.

BULGULAR

MTT analizi sonuçları, Val-Trp'nin MCF-7 hücre canlılığı üzerinde zaman ve doza bağlı bir etki gösterdiğini ortaya koymaktadır (Şekil 1). 24 saat tedavi edilen MCF-7 hücrelerinde, 0.1 mg/ml Val-Trp uygulaması sonucunda hücre canlılığında hafif bir artış (%101,3) gözlemlenmiş, 0.25 mg/ml konsantrasyonunda ise canlılık %83,3'e düşerek kontrol grubuna kıyasla istatistiksel olarak anlamlı azalma göstermiştir ($p < 0,0001$). 0.5 mg/ml Val-Trp

uygulanan MCF-7 hücrelerinde, 24. saatte hücre canlılığında daha sınırlı ancak anlamlı bir azalma saptanmış, 1 mg/ml'de ise 24. saatte canlılık kontrol ile benzer seviyelerde (%98) kalmıştır.

48 saat Val-Trp uygulanan grupta ise düşük ve orta konsantrasyon uygulandığında (0.1–0.5 mg/ml) hücre canlılığının tüm gruplarda kontrole göre anlamlı azalma izlenmiştir. En belirgin sitotoksik etki 1 mg/ml Val-Trp uygulamasında ortaya çıkmış ve hücre canlılığı 48. saatte %52'ye gerileyerek kontrol grubuna göre son derece anlamlı bir azalma göstermiştir ($p < 0,0001$). Bu bulgular, Val-Trp'nin özellikle yüksek konsantrasyonda ve uzun süreli maruziyette MCF-7 hücreleri üzerinde belirgin sitotoksik etki oluşturduğunu göstermektedir.

Şekil 1. Val-Trp'nin MCF-7 hücre canlılığı üzerindeki etkisi (*$p < 0.05$, ****$p < 0.0001$).

1 mg/ml Val-Trp uygulanan MCF-7 hücrelerinde, 24 ve 48 saatlik inkübasyon süreleri karşılaştırıldığında belirgin bir zaman bağımlı etki gözlenmiştir. 24 saatlik inkübasyon sonrasında, hücre canlılığı kontrol grubuna yakın seyretmiş (%98) ve bu konsantrasyonda kısa süreli maruziyetin anlamlı bir sitotoksisite oluşturmadığı görülmüştür. Buna karşın, aynı konsantrasyonda 48 saatlik inkübasyon sonrasında hücre canlılığının %52'ye düşmesi, yaklaşık %50 oranında bir azalma ile belirgin bir sitotoksik etkinin zamanla ortaya çıktığını göstermektedir. Bu sonuçlar, Val-Trp'nin yüksek konsantrasyonda etkisinin gecikmeli ortaya çıktığını ve uzun süreli maruziyet koşullarında MCF-7 hücreleri üzerinde antiproliferatif/sitotoksik potansiyele sahip olabileceğini düşündürmektedir.

TARTIŞMA

Bu çalışmada, triptofanın indol çekirdeğini içeren valil-triptofan (Val-Trp) dipeptidinin insan meme kanseri MCF-7 hücreleri üzerindeki sitotoksik etkileri değerlendirilmiş ve Val-Trp'nin hücre canlılığı üzerinde hem konsantrasyona hem de inkübasyon süresine bağlı farklı yanıtlar oluşturduğu gösterilmiştir. Düşük konsantrasyon olan 0.1 mg/ml'de 24. saatte hücre canlılığında hafif bir artış gözlenmesi, bu dozun proliferasyonu baskılayacak düzeyde toksik olmadığını ve hatta hücrelerin metabolik aktivitesini geçici olarak artırabileceğini düşündürmektedir. Bununla birlikte, aynı dozda 48. saatte canlılığın %83.3'e gerilemesi, daha uzun maruziyetle birlikte hafif–orta düzeyde sitotoksik etkinin ortaya çıktığına işaret etmektedir.

Orta konsantrasyon olan 0.25 mg/ml'de 24. saatte canlılığın %83.3'e düşmesi, Val-Trp'nin bu dozda erken dönemde belirgin bir antiproliferatif etki oluşturduğunu göstermektedir. Buna karşın 48. saatte canlılığın %94.3'e yükselmesi, hücrelerin bu dozda kısmen toparlanabildiğini, bir adaptasyon yanıtı gelişebildiğini veya hayatta kalan

hücrelerin kompansatuvar proliferasyon gösterdiğini düşündürebilir. Bu durum, Val-Trp'nin belirli konsantrasyon aralıklarında sınırda veya geri döndürülebilir bir toksisite profiline sahip olabileceğini ortaya koymaktadır.

En yüksek konsantrasyon olan 1 mg/ml'de ise belirgin bir zaman bağımlı sitotoksisite dikkat çekmektedir. Yirmi dördüncü saatte canlılığın %98 düzeyinde kalması, kısa süreli maruziyetin anlamlı bir toksisite oluşturmamasına rağmen, 48. saatte canlılığın %52'ye düşmesi güçlü ve gecikmeli bir sitotoksik etkinin ortaya çıktığını göstermektedir. İndol içeren peptit ve dipeptitlerin literatürde apoptoz indüksiyonu, anjiyogenez inhibisyonu, hücre döngüsü duraksaması ve ROS artışı gibi mekanizmalar üzerinden antikanser etki gösterebildiği bildirilmiştir; Val-Trp için gözlenen bu zaman–doz ilişkisi söz konusu mekanistik çerçeveyle uyumludur (Huang ve ark., 2017; Borse ve ark., 2023; Küçükbay ve ark., 2024).

SONUÇ

Sonuç olarak, Val-Trp dipeptidinin MCF-7 meme kanseri hücreleri üzerinde zamana ve konsantrasyona bağlı sitotoksik etkiler gösterdiği ortaya konmuştur. Düşük ve orta konsantrasyonlarda (0.1 ve 0.25 mg/ml) hücre canlılığında sınırlı ve kısmen geri döndürülebilir değişiklikler gözlenirken, 1 mg/ml konsantrasyonda 48 saatlik maruziyet sonrasında hücre canlılığı yaklaşık %50 oranında azalmıştır. Bu bulgular, Val-Trp'nin özellikle yüksek konsantrasyonda ve uzun süreli uygulamalarda güçlü bir antiproliferatif/sitotoksik potansiyele sahip olduğunu ve indol bazlı yeni antikanser ajanların geliştirilmesi açısından dikkate değer bir aday olabileceğini göstermektedir. Gelecekte yapılacak çalışmalarda, Val-Trp'nin etki mekanizmalarının moleküler düzeyde aydınlatılması, farklı kanser ve normal hücre hatlarında seçiciliğinin araştırılması ve uygun in vivo modellerde terapötik etkinlik ve güvenlilik profilinin değerlendirilmesi gerekmektedir.

TEŞEKKÜR

Çalışma sırasında yardımlarını esirgemeyen Doç. Dr. Bilge Bıçak'a tüm içtenliğimle teşekkürlerimi sunarım.

Özet

Bu çalışma GUL Herbaryumu'nda bulunan Caryophyllaceae familyasının envanterini ortaya çıkarmak için yapılmıştır. Çalışma son 3 yılın ürünüdür. Envanter işlemleri sırasında ilgili örnekler taksonomik ve sistematik açıdan incelenmiştir. GUL Herbaryumu bölgesel ve uluslararası 'GUL' kodu ile bilinen Süleyman Demirel Üniversitesi bünyesinde bir herbaryumdur. Bünyesinde ülke genelinden özellikle Göller Yöresi ve Doğu Anadolu'dan toplanan 25000 kadar bitki örneği barındırır. Bu örnekler içerisinde 4000 kadarı *Rosa* cinsine; 2000 kadarı da Caryophyllaceae familyasına aittir. Ranunculaceae, Apiaceae, Fabaceae ve Lamiaceae familyaları örnekleri de herbaryumda binlercedir. Bu bildiride Caryophyllaceae familyasına ait örneklere ait bazı bilgiler verilmektedir. Türkiye'nin hemen her bölgesinden toplanan ve herbaryum örneği haline getirilen 1868 koleksiyona ait bitki örnekleri tarafımızdan incelenmiş, usulüne göre kartonlara yapıştırılıp teşhis edildikten sonra herbaryum defterine kaydedilmiştir. Türkiye Florası adlı eserdeki sıraya göre dolaplara dosyalar halinde yerleştirilmiştir. Bitkilerin böcek tasallutundan korunması ve birbirleriyle karışmasını önlemek için plastik kilitli poşetlerle konulmuştur. Bitki örneklerinin teşhisi kontrol edilmiş; teşhissiz olanlar ise teşhis edilerek dosyalanıp dolaplara yerleştirilmiştir Teşhis işlemleri Flora of Turkey adlı esere göre, kısmen de yeni sistematik yayınlara göre yapılmıştır. *Silene, Bolanthus, Bolanthus, Arenaria* cinsleri RTF uzmanları tarafından kontrol edilmiştir. Toplamda 24 cinse bağlı 192 taksonun herbaryumda örneklerinin varlığı tespit edilmiştir. Herbaryumda; *Gypsophila*, *Silene*, *Dianthus* ve *Bolanthus'*a ait örnek ve takson sayısı diğer cinslere oranla daha fazladır. *Ankyropetalum* cinsinin tüm üyeleri, *Gypsophila* ve *Saponaria* cinsinin Türkiye taksonlarının tamamına yakını herbaryumda mevcuttur. Familyanın taksonları üzerine çok sayıda sistematik ve taksonomik çalışma yapılmıştır. Ancak cins veya türlerin sistematik durumu hâla ciddi bir bilimsel temele oturtulamamıştır. Bunların başında *Silene* ve *Bolanthus* gelmektedir. Bu durum; familyanın sistematik açıdan zorluğu, herbaryumlardaki materyal durumu ve araştırıcıların deneyim seviyesi ile açıklanabilir. Çalışma sonrası elde edilen sonuçlar *Caryophyllaceae* familyasının Türkiye'deki taksonomik durumunun hala karmaşık olduğunu ve küçük, doğal gruplar (seksiyon gibi) revizyon çalışmalarının gerekli olduğunu ortaya koymaktadır.

Notes on the inventory of the Caryophyllaceae family in the GUL Herbarium

Abstract

The present study was conducted with the objective of compiling a comprehensive inventory of the family *Caryophyllaceae* represented in the Rose Herbarium of Süleyman Demirel University. This research constitutes the culmination of a three-year project focusing on the taxonomic and systematic evaluation of the family. Throughout the inventory process, all relevant specimens were subjected to detailed examination and identification procedures. The Rose Herbarium, internationally recognized under the code "GUL," houses approximately 25,000

plant specimens collected from various regions of Turkey, with particular emphasis on the Lakes Region and Eastern Anatolia. Among these, nearly 4,000 specimens belong to the genus *Rosa*, while approximately 2,000 specimens are members of the family *Caryophyllaceae*. The collection also contains significant representatives of the families *Ranunculaceae*, *Apiaceae*, *Fabaceae*, and *Lamiaceae*. A total of 1,868 specimens belonging to the *Caryophyllaceae* family were analyzed in this study. Each specimen was mounted, labeled, and recorded according to standard herbarium protocols, and systematically arranged following the classification system adopted in *Flora of Turkey*. To ensure preservation, specimens were stored in sealed plastic bags to prevent insect damage and cross-contamination. Identification was verified primarily with reference to *Flora of Turkey* and supplemented by recent systematic revisions. Specialists examined the genera *Silene*, *Bolanthus*, and *Arenaria*. As a result, 192 taxa representing 24 genera were identified within the herbarium. The genera *Gypsophila*, *Silene*, *Dianthus*, and *Bolanthus* were found to be dominant. Despite extensive taxonomic research, the systematic relationships within *Caryophyllaceae* remain complex. The results of this study emphasize the necessity of further revisionary investigations, particularly focusing on smaller, natural groups (e.g., sections) to clarify the taxonomic status of the family in Turkey.

GİRİŞ

Caryophyllaceae familyası Dünyada takson sayısı bakımından büyük bitki familyalarındandır. Yaklaşık 100 cins ve 3000'den fazla tür ile temsil edilmekte olup çoğunluğu ılıman iklim kuşaklarında yayılış göstermektedir (Xue B ve ark., 2023) Caryophyllaceae familyası taksonları böceklerle tozlaşır. Türkiye'de genelde İran-Turan elementi ve volkanik ve kalker kayalı step vejetasyonu bitkileridir. Familyanın taksonları deniz seviyesinden (3500-4000) m'ye kadar, hemen her mevsimde görülebilirler. Türkiye florasında Caryophyllaceae familyası oldukça zengin bir çeşitliliğe sahiptir ve endemizm oranı yüksektir. Türkiye florasının yaklaşık 1/3'ü günümüz iklim şartlarının ortaya çıkmasından daha önce oluşan kalıntı (relikt) veya endemik bitkilerdir (Çiçek ve ark., 2017). Ortalama olarak her 20 günde bir bitki taksonu Türkiye florasına eklenmektedir. Bu çeşitlilik, çevre ülke floraları ile karşılaştırıldığında Türkiye bitki çeşitliliğinin ne kadar zengin olduğunu net olarak ortaya koymaktadır.

Caryophyllaceae (Karanfilgiller) familyasındaki *Dianthus, Silene, Gypsophila* ve *Agrostemma* cinsleri süs bitkileri olarak kullanılabilirken; *Stellaria, Cerastium, Arenaria* vs. peyzaj düzenlemeleri açısından önemlidir. *Saponaria, Ankyropetalum* ve *Gypsophila* cinsinin bazı taksonları saponin bakımından zengindir ve endüstriyel açıdan önemlidir. Kimya sanayiinde saponin önemli bir maddedir. Saponin kimyasal bileşiği bakımından zengin olan Caryopyllaceae familyasındaki taksonların ekonomik açıdan önemi vardır. *Ankyropetalum* ve *Gypsophila* cinsine ait türler, bazı gıdalarda ham madde olarak kullanıldığı için familyanın ekonomideki önemini artırır. Caryophyllaceae familyası taksonlarının tamamı az veya çok zehirlidir; bu nedenle tıbbi öneme sahiptir. *Minuartia, Arenaria, Cerastium, Silene* ve *Dianthus* cinslerinden peyzaj, salon bitkisi olarak kültüre alınanlar bulumaktadır. Çoğunlukla doğal bitkilerdir. *Dianthus* ve *Silene*'nin bazı türleri, *G. paniculata*'nın kültürü yapılmaktadır. Isparta'da karanfil üreten seralar son yıllarda çokça artmış, yöreye ekonomik katkı sağlamıştır. Ekonomik öneminden ve sistematik problemlerinin çokluğundan dolayı GUL herbaryumu çalışanları bu familya taksonlarına önem vermişler, çalışma konusu seçmişlerdir. Böylelikle GUL Herbaryumu tahminen Türkiye'deki en çok Caryophyllaceae familyasına ait örnek barındıran bir herbaryum olmuştur. Biz de bu zenginliği çeşitli açılardan bilim dünyasına ve meraklılara açıklamak istedik.

Türkiye florası için yazılan ilk eser "*Flora Orientalis*" (Boissier, 1865-1876)'dir. Daha sonra Davis (1965-1985)'in editörlüğünde 9 ciltten oluşan 'Flora of Turkey and the East Aegean Islands' adlı kitap yayınlanmıştır. Türkiye Florası'na eklenen yeni takson ve statü değişikliklerini içeren tamamlayıcı (supplement) nitelikli 10. (Davis ve ark., 1988) ve 11. ciltler (Güner ve ark., 2000) yayınlanmıştır. Son olarak Türk botanikçiler tarafından hazırlanan Türkiye Bitkileri Listesi (Damarlı Bitkiler) (Güner ve ark., 2012) ile Türkiye'nin bitki florasındaki çeşitliliği daha net bir şekilde ortaya koymuştur. Türkiye Bitkileri Listesi kitabında; Türkiye Florası 167 familya içerisinde, 1320 cins altında 9.996 türe ait ve tür altı taksonlarla birlikte toplam 11.707 bitki taksondan olarak belirtilmiştir (Güner ve ark., 2012). Daha sonra bu esere yeni taksonlar da eklenmiştir ve halen eklenmeye devam

edilmektedir. Dünya genelinde familya ve cinsleri tanıtan önemli kişiler ve araştırmaları vardır (Barkaudah, 1962; Greuter, 1995; Huber-Morath ve ark., 1967).

MATERYAL VE METOT

Bu araştırmanın materyalini GUL Herbaryumu'ndaki 1984-2023 yılları arasında Türkiye'nin farklı şehirlerinden toplanarak değerli koleksiyon materyali haline getirilmiş Caryophyllaceae familyasına ait taksonların örnekleri oluşturmaktadır. Önceden familyaya ait tanımlanmış taksonlar yeniden kontrol edilmiştir. Teşhis çalışmalarımızda (Davis, 1965-1985; 1988; Güner ve ark., 2000)'in 'Flora of Turkey and the East Aegean Islands' eseri temel kaynak olarak kullanılmıştır. Bu eserin yayınlanmasından sonra çıkan yayınlar (Güner ve ark., 2012; Özhatay ve ark., 2009) teşhis ve envanter kayıt işlemlerinde dikkate alınmıştır. Yeni takson kayıtları (Armağan, 2016; Armağan ve ark., 2017; Ataşlar ve Ocak, 2005; Aytaç ve Duman, 2004; Özçelik, 2023; 2024; Yıldırımlı, 2012) adlandırmalarda dikkate alınmıştır. Bununla birlikte sistematik çalışmalar (Alpınar, 1994; Fidan ve Özgökçe, 2016; Özçelik ve Kılıç, 2007; Özçelik ve Özgökçe, 1995; 1999; 2023; 2024) taksonların ayırt edilmesinde özenle incelenmiştir. Çalışmalarımız devam etmektedir. Tamamlandığında familyanın envanter kaydı GUL Sanal Herbaryumuna yüklenerek isteyenlerin internet ortamında ulaşabilmesine imkan sağlanacaktır.

BULGULAR ve TARTIŞMA

Araştırmanın ön sonuçlarına göre; GUL Herbaryum'daki *Caryophyllaceae* familyasına ait yaklaşık olarak 1760 nüsha bitki örneğinin değerlendirilmesi sonucu, toplam 24 cins ve yaklaşık 190 takson tespit edilmiştir. Endemik takson sayısı ise yaklaşık 93 olarak belirlenmiştir. Bu çalışmada elde edilen ön verilere göre; Caryophyllaceae familyasına ait aşağıdaki sonuçlara ulaşılmıştır:

Silene, Arenaria, Minuartia, Bolanthus ve *Gypsophila* cinsleri; özellikle *Silene oligotricha*, *S. leptoclada, S. odontopetala, S. caryophylloides* vb. taksonomik açıdan problemlidir. Ayrıca örnekler içerisinde *Gypsophila* cinsinde bulunan *G. sphaerocephala, G. bitlisensis* gibi sistematik açıdan çok sayıda problemli takson bulunmaktaydı. Bu türler üzerine revizyon çalışmaları yapıldı ve sorun çözülmüştür. *Gypsophila* cinsinde 39 tür ve 650 koleksiyon örneği incelenerek içerisinde endemik taksonlar belirlenmiştir.

Silene, Gypsophila gibi büyük cinslerde ise cins bazında değil, seksiyon bazında revizyonlar yapılmalıdır. *Gypsophila* cinsi (Korkmaz ve Özçelik, 2011; Muca, 2017; Özçelik ve Özgökçe, 1995; 1999; 2023; 2024) ve *Silene*'nin 2 seksiyonu *(Auriculatae* Boiss. and *Brachypodeae* Boiss.) revize edilmiştir (Özçelik ve Kılıç, 2007). *Hagenia* Seksiyonu da revize edilmiştir (Fidan ve Özgökçe, 2016). *Bufonia* cinsinin (Serdaroğlu, 2001) Flora'daki (Davis, 1967) türleri revize edilmiştir. Ancak bu cinse ait daha sonra 2 yeni tür eklenmiştir. Cinsler ve *Silene, Gypsophila* gibi büyük cinslerde seksiyon anahtarları yapılmadan familya bazında revizyon yapmak teknik olarak hatalı bir çalışmadır. Bu nedenle yapılan tür ve cins teşhis anahtarları pek çalışmamaktadır. *Gypsophila* için seksiyon anahtarı (Özçelik ve Özgökçe, 2024) tarafından yapılmıştır. *Silene* L. Türkiye'de *Caryophyllaceae* familyasına ait en büyük cinstir ve yaklaşık 150 tür ile temsil edilmektedir. (W. Greuter, 1995) tarafından seksiyonlar belirlenmiş ve bir teşhis anahtarı yapılmış olmasına rağmen güncellenmesi yapılmamıştır. Çalışmamızda *Silene* cinsi içerisinde 52 takson belirlenmiş, bunlardan 31 takson endemiktir.

Bolanthus, Gypsophila, Ankyropetalum ve *Acanthophyllum* daha önceleri bir cins iken sonradan farklı cinslere bölünmüştür. Bu cinslerin sistematik karakterleri iç içe girmiştir; cins teşhis anahtarı net değildir. Resimli Türkiye Florası'nda (Güner ve ark., 2025) da bu problemlerin çözülemediği aşikardır. *Bolanthus* küçük bir cins olmasına rağmen taksonomik açıdan çok zor bir cinstir. Cinsin güvenilir bir tür teşhis anahtarı yoktur. Tarafımızdan yapılmaya çalışılmaktadır. Özellikle *B. minuartioides* ile *B. spergulifolius* kolayca teşhis edilemez. Her bir cins üzerinde uzun süreli çalışmalar gerekir. (Özçelik ve Muca, 2010) cinsleri üzerine sistematik çalışmalar yapılmıştır. Aynı şekilde ekolojik çalışmalar (Armağan ve Özgökçe, 2018) yapılmıştır. RTF'de (Güner, 2025) *Silene* cinsine ait bazı türlerin kısmen akraba, ya da uzak akraba türleri ile (*Silene guerbuezii, S. denizliensis* ile); *(S. eminentis, S. armena* ile) vs. karıştırıldığı görülmüştür. Bu durum araştırıcıları tereddüte sevk edecek ciddi bir hatadır. Esasen metot hatasıdır. Çünkü seksiyonlar belirlenip ayrım kriterleri oluşturulmadan ve komplex türler revize edilmeden (*S. araratica, S. odontopetala, S. caryophylloides* gibi) tür teşhis anahtarı yapılmamalıydı. Ancak bu işleri yapmanın uzun yıllar alacağı da bir gerçektir. Bu nedenle sistematikte sürekli git-geller olabilmektedir.

Herbaryumda; *Silene* cinsi içerisinde 31 Endemik takson, 2 nüsha Holotype örnek, 7 nüsha Isotype örnek, 25 nüsha Topotype örnek kayıt altına alınmıştır. Bir de *Bolanthus* için holotip ve izotipler vardır.

Bolanthus cinsi morfolojik açıdan tür belirlenmesi en zor olan cinslerden biri olması nedeniyle incelemeler sonucunda yanlış adlandırmalar düzeltilmiştir. Ayrıca cinse ait 9 Endemik takson belirlenmiştir. Türkiye taksonlarının tamamının endemik olduğu görülmüştür. Flora'ya göre (Davis, 1967) endemik cinslerden idi ve 5 türü kayıtlı idi. Günümüzde 13 türü Türkiye'de olmak üzere toplam 20 kadar türü belirlenmiş ve cins endemik olmaktan çıkarılmıştır. *Dianthus*, Türkiye Florası'nda (Davis, 1967) yaklaşık 80 tür ile temsil edilmektedir. Yapılan değerlendirmelerde *Dianthus* içerisinde 68 nüsha örnek incelenmiş olup bunlardan da 8 endemik takson belirlenmiştir.

SONUÇ VE ÖNERİLER

Çalışmamızın sonuçları; Caryophyllaceae familyası türlerin teşhisinde kullanılan karakterlerin bazen tür içi varyasyonlarla karışabildiğini göstermektedir. Davis (1965-1985; 1988) tarafından yapılan sınıflandırmalar önemli bir temel olmakla birlikte, son yıllarda yapılan moleküler çalışmalar (Fior ve ark., 2006; Rautenberg ve ark., 2010) bazı türlerin sistematik konumlarını yeniden değerlendirmeyi gerekli kılmıştır. Türkiye florasında familyanın yüksek endemizm oranı, morfolojik farklılıkların çevresel adaptasyonlarla ilişkili olabileceğini düşündürmektedir. Bu nedenle morfolojik bulguların moleküler veriler yanında ekolojik verilerle de desteklenmesi gereklidir. Sadece morfolojik farklılık veya benzerliklere göre bir sınıflandırma yapılmamalıdır. Hatta coğrafi dağılış özellikleri de dikkate alınmalıdır. Böyle yapılmazsa birbirine akraba türler bir türmüş gibi işlem görebilir. RTF'de (Güner, 2025) *Silene* cinsinde görülen durum işte budur. Türkiye Bitkileri (Güner ve ark., 2012) kitabı bir derlemedir. Bir revizyon sonucu yazılmamıştır. Hal böyle iken RTF'de bu kitap ölçü alınmıştır. Bölgesel bir endemik olan *S. armena* içerisine çok sayıda takson konulmuş, diğerleri sinonim yapılmıştır. Coğrafi olarak bir inceleme yapılsaydı böyle bir hata olmayabilirdi. Ayrıca 2000 yılında son cilti yayınlanan (Güner ve ark., 2000) Türkiye Florası adlı eserden sonra çok sayıda yeni takson tanımı yapılmıştır. 25 yıllık sürede Türkiye florasının daha zenginleşmesi beklenirken genel durum olarak sayıların düşmesini anlamak zordur. Mesela 175 iletim demetli bitki familyası niçin daha aşağı düşmüştür gibi soruların cevabı aranmaktadır. Caryophyllaceae familyası Türkiye florasındaki önemli bir taksonomik karmaşıklık olduğu gözlemlendiği için GUL Herbaryumu'nda bulunan örneklerin revizyon çalışması ile morfolojik incelemeler ve literatür karşılaştırmalarıyla mevcut taksonomik bilgilerin güncellenmesine katkı sağlayacağı kanaatindeyiz.

Araştırma sayesinde, türleri belli olmayan herbaryum örneklerinin teşhisleri yapılmış (Güner ve ark., 2012), daha önceden tanımlanmış olan herbaryum örnekleri ise yeniden kontrol edilmiştir. Ayrıca Caryophyllaceae familyasına ait tüm bitki örnekleri kontrol edilerek yıpranmış olan herbaryum örneklerinin karton, gömlek ve üstlerindeki etiketleri yenilenerek bitki örnekleri teşhis ve tanımlama tarihlerine uygun olarak sıraya dizilmiştir. Materyal olarak kullanılmış olan tüm bitki örnekleri, çalışma yapılırken zarar görmemesine dikkat edilerek incelenmiş ve halen bulundukları Isparta Süleyman Demirel Üniversitesi Mühendislik ve Doğa Bilimleri Fakültesi bünyesinde GUL Herbaryumu'nda korunmaktadır.

TEŞEKKÜR

GUL Herbaryumu'na çok sayıda araştırmacı bitki hediye etmiştir. Bu örneklerin çoğunluğu da TUBITAK, SDÜ Rektörlüğü tarafından desteklenen projeler kapsamında toplanıp araştırılmıştır. Revizyon yapan ya da bitki hediye eden araştırıcılar sayesinde herbaryum bugünkü zengin duruma getirilmiştir. Herbarum'un bağlı olduğu SDÜ. Mühendislik ve Doğa Bilimleri Fakültesi Dekanlığına, araştırma projelerine finansal destek veren kurumlara ve proje araştırmacılarına, ayrıca herhangi bir sebeple herbaryuma örnek bağışlayan tüm kişilere teşekkür ederiz.

Özet

Melanomlarda santral sinir sistemi (SSS) metastazı, hastalık biyolojisinin en agresif biçimlerinden biridir. Beyin metastazı gelişimini belirleyen moleküler mekanizmalar henüz net olarak aydınlatılamamış olup, özellikle transkripsiyonel düzeyde farklılaşmalar olduğu ileri sürülmektedir. Çalışmamızda, beyin metastazı olan ve olmayan melanom olguları arasındaki moleküler farklılıkları ortaya koymayı amaçladık.
Cbioportal biyoinformatik web sitesi üzerinden, "Metastatic Melanoma (DFCI, Nature Medicine)" veri seti kullanıldı. İki grup arasında, DNA mutasyonu, kopya sayısı değişiklikleri (CNV) ve mRNA ekspresyon düzeyleri karşılaştırıldı. P ve q < 0,05 değeri istatistiksel olarak anlamlı kabul edildi.
Gruplar arasında, DNA mutasyon profili ve CNV açısından anlamlı bir fark izlenmezken, mRNA ekspresyon düzeyi bakımından farklılık gösteren 267 adet gen (DEGs) saptandı. En yüksek anlamlılığa sahip genler arasında AQP7, IGLV-46, IGHV3-64, FCRL5 gibi immün ve membran ilişkili genlerin yer alması, beyin metastazlarının immün mikroçevre ve nöral dokuya özgü çevresel baskılarla ilişkili olduğunu düşündürmektedir. Buna karşılık, beyin metastazı olmayan olgularda metabolik ve proliferatif süreçlerle bağlantılı bir gen kümesinin yüksek ekspresyonu, metastatik fenotip ile beyin tropizmi arasındaki ayrımı desteklemektedir. Bu bulgular, melanom beyin metastazının genomik değil, transkripsiyonel düzeyde belirgin şekilde ayrıştığını göstermekte ve AQP7 gibi bazı genlerin potansiyel biyobelirteç adayı olabileceğini ortaya koymaktadır. Sonuçlar, SSS metastaz biyolojisinin anlaşılmasına katkı sağlayarak gelecekteki fonksiyonel çalışmalar için temel oluşturmaktadır.

Anahtar Kelimeler: Melanom, Beyin metastazı, DEGs

Molecular mechanisms involved in the development of brain metastases in melanoma

Abstract

Central nervous system (CNS) metastasis in melanoma represents one of the most aggressive forms of the disease. Although the molecular mechanisms underlying the development of brain metastases have not yet been fully elucidated, it has been suggested that transcriptional-level alterations may play an important role. In this study, we aimed to identify the molecular differences between melanoma cases with and without brain metastasis. The "Metastatic Melanoma (DFCI, Nature Medicine)" dataset available on the cBioPortal bioinformatic platform was used. DNA mutations, copy number variations (CNVs), and mRNA expression levels were compared between the two groups. p and q value < 0.05 was considered statistically significant.

No significant differences were observed between the groups in terms of DNA mutation profiles or CNVs. However, mRNA expression analysis identified 267 differentially expressed genes (DEGs). The presence of highly significant genes such as AQP7, IGLV-46, IGHV3-64, and FCRL5—many of which are immune- or membrane-associated—in cases with brain metastasis suggests that immune microenvironment adaptation and neural tissue–specific selective pressures may contribute to the metastatic process. Conversely, the higher expression of a broad set of genes related to metabolic and proliferative pathways in the non-metastatic group supports a biological distinction between systemic metastatic behavior and brain tropism. These findings demonstrate that melanoma brain metastasis is characterized not by genomic alterations but by distinct transcriptional reprogramming. Moreover, the identification of genes such as AQP7 as differentially expressed highlights potential biomarker

candidate. Overall, the results contribute to a better understanding of CNS metastasis biology and provide a basis for future functional studies.

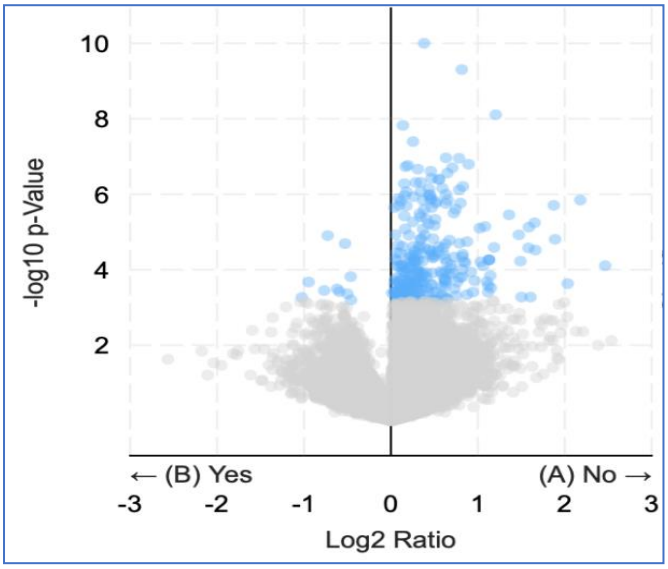
Keywords: Melanoma, Brain metastasis, DEGs

GİRİŞ

Melanomun santral sinir sistemi (SSS) tropizmi, yayınlanmış birçok seride ileri evre melanom hastalarının önemli bir çoğunluğunda beyin metastazı geliştiğinin gösterilmesi ile desteklenmiştir (Rabbie ve ark. 2021). Bu oran, melanom hücrelerinin kan–beyin bariyerini aşabilme, sinir sistemi mikroçevresine tutunabilme ve bu alanda proliferatif kapasitesini sürdürmeye özgü programlar taşıdığını düşündürmektedir (Radke ve ark. 2022). Multiomik çalışmalarda, beyin metastazlarının genetik olarak primer tümörle büyük ölçüde benzer olduğunu, ancak transkripsiyonel düzeyde belirgin farklılık gösterdiğini ortaya koymuştur (Biermann ve ark. 2022).

Beyin metastazlarının oluşumunda immün mikroçevre ve nöral niş adaptasyon mekanizmalarının temel rol oynadığı gösterilmiştir. Özellikle beyindeki tümöral mikroçevrenin periferik immün yanıttan farklı yapısı, metastatik hücrelerin farklı immün kaçış mekanizmaları geliştirmesine neden olmaktadır (Quail ve Joyce 2017). Tek hücre düzeyinde yapılan çalışmalar, beyin metastazında immün baskılanmış bir mikroçevre, reaktif astroglial cevap, tümör hücrelerinin sinaptik benzeri sinyal yollarını taklit eden nöronal adaptasyon süreçlerinin mevcut olduğunu göstermiştir (Priego ve ark. 2018; Klemm ve ark. 2020). Ayrıca, metabolik programların yeniden düzenlendiği ve oksidatif stres yanıtının beyin metastazlarında sistemik metastazlardan farklı olduğu belirtilmiştir (Fischer ve ark. 2019).

Bu nedenle beyin metastazı bulunan melanomların transkripsiyonel düzeyde karakterize edilmesi hem biyolojik mekanizmaların anlaşılması hem de olası prognostik imzaların belirlenmesi açısından kritik öneme sahiptir (Alvarez-Breckenridge ve ark. 2022). Çalışmamızda, "Metastatic Melanoma (DFCI, Nature Medicine)" veri setindeki olgular analiz edilerek beyin metastazı bulunan ve bulunmayan hastalar arasındaki moleküler farklılıkları ortaya koymayı amaçladık.



MATERYAL VE METOT

Çalışmamızda, Cbioportal online biyoinformatik servisi üzerinden "Metastatic Melanoma (DFCI, Nature Medicine)" veri seti kullanıldı (https://www.cbioportal.org) (Cerami ve ark. 2012; Liu ve ark. 2019). Bu veri setinin içerdiği 144 adet olgudan beyin metastazı bulunan ve bulunmayan olgular belirlenerek iki grup arasındaki moleküler farklar sırasıyla, "Genomic alterations" ve "mRNA" sekmeleri altında karşılaştırıldı. P ve q değeri için 0,05 istatiksel olarak anlamlılık sınırı kabul edildi.

BULGULAR

Çalışmamıza, "Metastatic Melanoma (DFCI, Nature Medicine)" veri setinde yer alan 144 olgu dahil edildi. Olgulardan 16'sında (%11,1) beyin metastazı bulunmaktaydı. Beyin metastazı bulunan olgulardan, 9'u kadın, 7'si erkekti.

İki grup arasında, DNA mutasyonu varlığı ve kopya sayısı değişiklikleri bakımından istatistiksel olarak anlamlı fark izlenmedi. mRNA ekspresyon durumları karşılaştırıldığında ise 267 gende farklı ekspresyon düzeyleri izlendi (Differantially Expressed Genes, DEGs) (Şekil 1). Bu genlerden, 10 tanesi metastaz izlenen grupta daha yüksek ekspresyon düzeyine sahipken 257 tanesi metastaz izlenmeyen grupta daha yüksek düzeyde eksprese edilmekteydi ($p<0,05$). En yüksek anlamlılığa sahip on gen sırasıyla şunlardı; AQP7 (p=4.96e-10, q=5.165e-6), IGLV-46 (p=7.81e-9, q=5.420e-5), SLC25A15P3 (p=4.02e-8, q=1.672e-4), PTGR (p=1.09e-7, q=3.297e-4), IGHV3-64 (p=1.11e-7, q=3.297e-4), FCRL5 (p=1.61e-7, q=3.747e-4), C12ORF42 (p=1.71e-7, q=3.747e-4), AKAP14 (p=1.86e-7, q=3.747e-4), PKHD1L1 (p=1.98e-7, q=3.747e-4), FDFF10 (p=2.15e-7, q=3.747e-4) (Tablo 1).

Şekil 1. Beyin metastazı bulunan ve bulunmayan olgular arasındaki DEGs

Tablo 1. Beyin metastazı bulunan ve bulunmayan olgular arasındaki en yüksek anlamlılığa sahip DEGs

FDFF10	2.15e-7	3.747e-4

TARTIŞMA

Bulgularımız, melanom beyin metastazının belirleyici biyolojik süreçlerinin genomik değişikliklerden çok transkripsiyonel düzeyde ortaya çıktığını göstermektedir. Literatürde beyin metastazlarının primer tümöre göre genetik açıdan büyük farklılıklar göstermediği, ancak transkripsiyonel düzeyde belirgin olarak ayrıştığı vurgulanmış olup bu durum "fenotipik plastisite" kavramını desteklemektedir (Biermann et al. 2022). Özellikle metastatik melanomlarda immün düzenleyici genlerin ve adezyon/mikroçevre etkileşimini yöneten transkripsiyonel değişikliklerin baskın olduğu gösterilmiştir (Alvarez-Breckenridge ve ark. 2022). Bu çalışmada saptanan 267 DEGs, beyin metastazı olan olguların belirli bir transkripsiyonel imzaya sahip olabileceği yönündeki bu modern görüşle uyumludur (Radke ve ark. 2022).

Beyin metastazı bulunan olgularda en yüksek ekspresyon farklılığı gösteren genlerin çoğunun immünoglobulin dizileri ve immün reseptörlerle ilişkili olması, santral sinir sistemi (SSS) mikroçevresinin immün baskılanmış yapısına karşı tümör hücrelerinin yeni immün etkileşim mekanizmaları geliştirdiği hipotezini desteklemektedir (Klemm ve ark. 2020). Beynin periferik immün hücre girişine sınırlı izin vermesi nedeniyle melanom hücreleri nöroimmün etkileşimleri etkisiz bırakan alternatif yollar geliştirmekte ve bu durum intrakraniyal metastazda farklı immün-transkripsiyonel programları ortaya çıkarmaktadır (Quail ve Joyce 2017). Bulgularımızdaki IGHV-IGLV aşırı ekspresyonu da bu immün yeniden programlanma sürecinin bir kanıtı olabilir.

Buna karşılık, beyin metastazı saptanmayan olgularda metabolik aktivite, oksidatif stres yanıtı ve hücre döngüsüyle ilişkili geniş bir gen grubunun daha yüksek eksprese edilmesi, sistemik metastatik hastalıkta proliferatif ve metabolik programların baskın olduğuna dair bilgiler içeren literatürle uyumludur (Fischer ve ark. 2019). Beyin metastazlarında bu genlerin belirgin şekilde azalması ise nöral nişin tümör hücrelerini farklı bir

fenotipe zorladığını, yani biyolojik baskının metabolik olmaktan çıkarak adezyon, immün düzenleme ve mikroçevre adaptasyonuna odaklandığını düşündürmektedir (Biermann ve ark 2022).
Çalışmamızda yüksek anlamlılık gösteren AQP7 gibi genleri içeren Aquaporin ailesinin hücresel sıvı dengesi, migrasyon ve invazyon basamaklarında önemli rolü olduğu bilinmektedir (Moon ve ark. 2022). Beyin dokusunun sıvı dengesi ve iyonik dengesi açısından hassas yapısı dikkate alındığında, aquaporinlerin özellikle beyne metastaz eğilimindeki grupta işlevsel rol oynayabileceği düşünülmektedir (Varricchio ve Yool 2023). Bu açıdanAQP7'nin yüksek ekspresyonu, beyin metastazı açısından potansiyel bir biyobelirteç adayı olarak görülebilir.

SONUÇ

Mevcut bulgular, melanom beyin metastazlarının genomik düzeyde belirgin bir ayrışma göstermediğini, ancak geniş kapsamlı bir transkripsiyonel yeniden programlama ile karakterize olduğunu ortaya koymuştur. Beyin metastazı bulunan olgularda immünoglobulin ilişkili genlerin ve AQP7 gibi bazı genlerin yüksek ekspresyon göstermesi, SSS mikroçevresine özgü immün ve nöral adaptasyon mekanizmalarının önemini desteklemektedir. Buna karşılık, metastazı olmayan grupta metabolik ve proliferatif genlerin daha yüksek ekspresyonu, sistemik metastatik fenotip ile beyin tropizmi arasındaki belirgin biyolojik ayrımı yansıtmaktadır. Bu bulgular, yeni biyobelirteç adayları ve potansiyel hedefler sunarak gelecekte yapılacak fonksiyonel ve translasyonel çalışmalara yön verebilir.

Abstract

In recent years, the increasing use of nuclear technology—particularly gamma radiation—has raised the importance of radiation protection. In this study, mass attenuation coefficients of cement-based samples produced by mixing dehydrated tinkal ore, obtained from the Balıkesir–Bigadiç region, with cement at specific ratios were measured to determine their gamma-ray absorption capacity. Within the scope of the research, Gamma Ray Absorption Experiments and XRD analyses were carried out.
Mass attenuation coefficients of the prepared samples were measured within the energy range of 13.375–385.851 keV. Significant changes, especially in the low- and medium-energy regions, were observed in comparison with non-additive samples. It was determined that the addition of tinkal decreases mass attenuation coefficients, with this decrease being more pronounced at higher energies. This behavior can be attributed to the low atomic number elements present in tinkal.

Keywords: Cement, Tinkal, Boron, Radiation, Gamma Attenuation

1. INTRODUCTION

Radiation is energy emitted from a source in the form of particles or electromagnetic waves traveling in straight lines. Its use has been increasing in fields ranging from medical applications to industrial operations (Sehhatigdiri, 2014). Radiation is classified into ionizing and non-ionizing categories. Ionizing radiation—such as alpha and beta particles, as well as X- and gamma rays—poses direct health risks.
The use of X-rays and gamma rays, in particular, for diagnostic and therapeutic purposes in medicine, such as radiation oncology, nuclear medicine, cardiology, and radiology, is quite widespread. Nuclear energy is also used as a significant source of electrical energy generation. Radiation is used in industrial applications in various regions. Radiation is also used to kill microorganisms during the sterilization process. Radiation is used to preserve food, extend the shelf life of food, and eliminate harmful microorganisms. Radioisotopes are also used for materials analysis, archaeological research, and monitoring and control in industrial processes. Various radiation-related legal permits are used in research. Radiation techniques and methods are used for research in many fields, including physics, chemistry, biology, archaeology, and materials science. Radiation safety and control are crucial (Karakoç 2024; Yılmaz 2011).
Gamma rays, which are electromagnetic radiation emitted during transitions between nuclear energy levels, have much higher energy and penetration capability than alpha or beta particles. For this reason, high-density materials are generally used for gamma-ray shielding (Köklü 2006).
With the expanding use of radiation, measures to protect against its harmful effects have become essential. Ionizing radiation can cause DNA damage, cellular malfunctions, acute effects at high doses, and stochastic effects such as cancer at lower chronic exposures (Eroglu 2009; Görpe 1992). The three basic methods of protection from these harmful effects are time, distance and armoring.

- Time: In long-term exposures, the exposure dose increases as time increases, resulting in a directly proportional effect. Therefore, the time spent in the environment near the source should be kept as short as possible. Reducing the exposure time is important for direct exposures, but keeping the exposure time short is even more crucial for fluoroscopy due to the high dose (Eroglu 2009; Keskin 2024).
- Distance: The dose exposure increases as one approaches the radiation source. Radiation intensity is inversely proportional to the square of the distance, a phenomenon known as the inverse square law. Appropriate warnings and signs should be installed in areas close to the radiation source (Eroglu 2009; Keskin 2024).
- Shielding: Materials placed in front of a radiation source, surrounding it and thus reducing its intensity, are called shielding. Protection is achieved by creating a barrier with materials that prevent the passage of the radiation source. Shielding should be made with materials and thickness appropriate to the type, energy, type, and intensity of each radiation. Lead shielding should be used to protect against ionizing radiation. Special lead-lined extraction rooms, lead barriers, and leaded personal protective equipment can effectively block ionizing radiation (Eroglu 2009; Keskin 2024).

This study investigated the gamma absorption capacity of tincal-based concrete, an alternative to lead shielding, which is currently widely used.

Concrete is a multi-component building material produced by mixing cement, water, sand, and various mineral additives such as silica fume, fly ash, and blast furnace slag in specific proportions. Portland cement is the most commonly used material in concrete production (Yılmaz 2011).

Tincal ($Na_2B_4O_7 \cdot 10H_2O$), a boron mineral, is inherently colorless and transparent, but can also appear in pink, yellowish, or gray tones due to various impurities. Its hardness ranges from 2 to 2.5 on the Mohs scale, and its specific gravity is approximately 1.7 g/cm³. Tincal can easily decompose, lose water, and transform into the mineral cinachalconite, depending on environmental conditions. One of the most important deposits of this mineral in Turkey is located in the Eskişehir-Kırka region. Also known as borax, tincal forms in salty lake environments as a result of the precipitation of evaporites and is found in association with other evaporite minerals such as carbonates, sulfates, and halite (DPT 2001; 2008).

In a previous study, Erdoğan (1998) produced different types of cement by adding ground boron minerals to cement and examined their physical and mechanical properties. He also evaluated the shielding capacity of boron minerals against neutron radiation in concrete using theoretical approaches. Based on the findings, he concluded that boron mineral addition positively affected shielding performance (Erdoğan 1998).

In 2008, Kharita and colleagues investigated the attenuation coefficients of concrete produced from aggregates commonly used in Syria by gamma rays (137Cs and 60Co isotopes) and neutrons (Am-Be source). The concretes were produced by mixing black beach sand, hematite, dolomite, and serpentine with beach sand in varying proportions. The results showed that concretes containing hematite were more effective in providing protection against both types of radiation (Kharita et al. 2008).

In 2010, Akkurt and his colleagues conducted a study using heavy concretes produced using barite and lead. They measured linear absorption coefficients using radioactive sources with energies of 0.662 MeV, 1.173 MeV, and 1.332 MeV using a NaI(Tl) detector. The results were compared with XCOM data. The results revealed that barite and barite-added heavy concretes are good gamma-ray absorbers, but their shielding properties are lower than those of lead (Akkurt et al. 2010).

This study includes the preparation of tincal added cement samples, determination of their physical and mechanical properties and experimental investigation of their radiation absorption capacity.

2. MATERIALS and METHODS

2.1. Materials

2.1.1. Materials used in experiments

In this study, the mineral tincal was used to investigate its neutron and gamma ray absorption properties. It is anticipated that this mineral may have potential applications as a radiation absorbing material in various fields.Deneylerde kullanılan çimento Aşkale Çimento Fabrikasından temin edilen Portland çimentosu (CEM I 42.5 R)'dur.

Tincal, a natural borate mineral with a high boron content, was obtained from the Kırka-Eskişehir region. Before being used in experimental studies, it underwent preliminary preparation processes such as grinding, drying, and sieve analysis. Following these processes, the samples were reduced to micron size and finally heat-treated at 650°C to remove the crystal water, resulting in anhydrous boron.

2.2. Methods

2.2.1. Production of concrete

The concretes examined in this study were produced at the Civil Engineering Department Laboratory of Erzurum Technical University. Six types of concrete were produced in this study: standard concrete, ulexite, and tincal-added concrete. First, cement-only samples were prepared for comparison. Then, 1%, 5%, and 10% tincal were added to each cement sample, sequentially and separately. The water/binder ratio was set at 0.20 in the experiments. The temperature of the sample was measured with a digital thermometer, and the mixing water temperature was determined to be between 25-30°C. The prepared samples were placed in 5x5x5cm cube sample molds. The samples were kept in their molds for 24 hours and then removed from the molds. During the curing process, the samples were maintained in a constant temperature environment (24°C), and the ambient temperature and relative humidity were regularly monitored with a digital thermometer.

2.2.4. Gamma spectroscopy system

The experimental measurements undertaken in relation to the attenuation coefficient of the concrete produced as part of the study were conducted at the High Energy Spectroscopy Laboratory, which is housed within the Department of Atomic and Molecular Physics at Atatürk University's Faculty of Science. The experimental setup utilized in the study is illustrated in Figure 1. In the experiment, the VEX (variable energy source) and Ba-133 radioisotope were utilized as the source.

The intensity of a photon flux, I_0, decreases with increasing thickness, t, of an absorbing material. The decrease in intensity is described by the Lambert-Beer law (Yilmaz, 2011) as the linear attenuation coefficient (LAC), given by the following equation:

$$\mu = -\frac{1}{t} ln(\frac{I}{I_0}) \qquad (cm^{-1})$$

However, the mass attenuation coefficient (μ/ρ), defined as the ratio of the linear attenuation coefficient (μ) to the sample density (ρ) and does not change depending on the phase of the material, is more commonly used. The mass attenuation coefficients (MACs) are determined using the intensity values measured experimentally in the experimental geometry shown in Figure 1(a) from the equation

$$\left(\frac{\mu}{\rho}\right) = -\frac{1}{\rho t} ln(\frac{I}{I_0})$$

where ρt is called the mass thickness. The unit of the mass attenuation coefficients is cm^2/g.

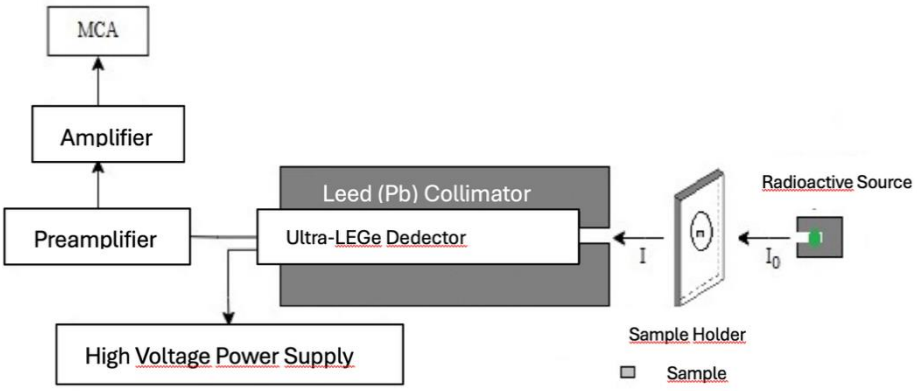

Figure 1. Experimental setup for gamma ray attenuation.

2.2.5. X-ray difraksiyon (XRD)

XRD analysis of the concretes produced within the scope of the study was measured by Erzurum Technical University, High Technology Application and Research Center (YUTAM).

2.2.6. Heat Treatment

The use of boron in the cement sector has become widespread, but boron ores are suitable for use up to a maximum of 2% water content (Kocadağistan and Arslan, 2024). Tincal was dewatered in a muffle furnace at 650°C for 6 hours. Following the heat treatment, the chemically bound water removal rate was calculated by taking the weight differences of tincal and ulexite ores. According to the calculations, 98% water removal was achieved in both ores (Arslan, H.2023; Ataç, H.2024).Tinkale ait XPS ve kimyasal analiz sonuçlarına göre tinkalin %47,2 H_2O içerdiği belirlenmiştir. Ağırlık farkı hesaplamaları sonucu H_2O içerikleri ısıl işlem sonrasında %1 seviyelerine düşürülerek deneylerde kullanılmıştır.

3. RESEARCH FINDINGS AND DISCUSSION

Cement, mixtures of cement and dewatered tincal at 1%, 5%, and 10% were examined, and their gamma absorption values are given below. When these values were examined, it was determined that the best value was 5% tincal, and XRD analyses were performed in accordance with these values.

3. 1. Gamma Absorption Tests of Tincal Additive Cement

The Gamma ray absorption results of the samples of the mixtures are given in Table 1 and Figure 2.

Table 1. Tincal gamma absorption test values

E (keV)	Control	Control + %1 Tincal	Control + %5 Tincal	Control + %10 Tincal
13,375	18,7	18,6	18,4	17,8
14,98	13,5	13,6	12,9	12,7
17,443	8,02	7,95	7,71	7,70
19,607	5,6	5,77	5,63	5,53
22,103	4,16	4,34	4,33	3,91
24,942	2,87	3,05	2,95	2,77
43,737	0,580	0,589	0,570	0,568
44,47	0,575	0,583	0,573	0,562
50,391	0,596	0,605	0,598	0,586
53,155	0,521	0,400	0,379	0,375
59,537	0,243	0,260	0,232	0,222
81	0,236	0,256	0,240	0,233
276,39	0,160	0,113	0,107	0,107
302,85	0,154	0,091	0,089	0,090
356,01	0,153	0,091	0,090	0,090
385,851	0,148	0,085	0,087	0,086

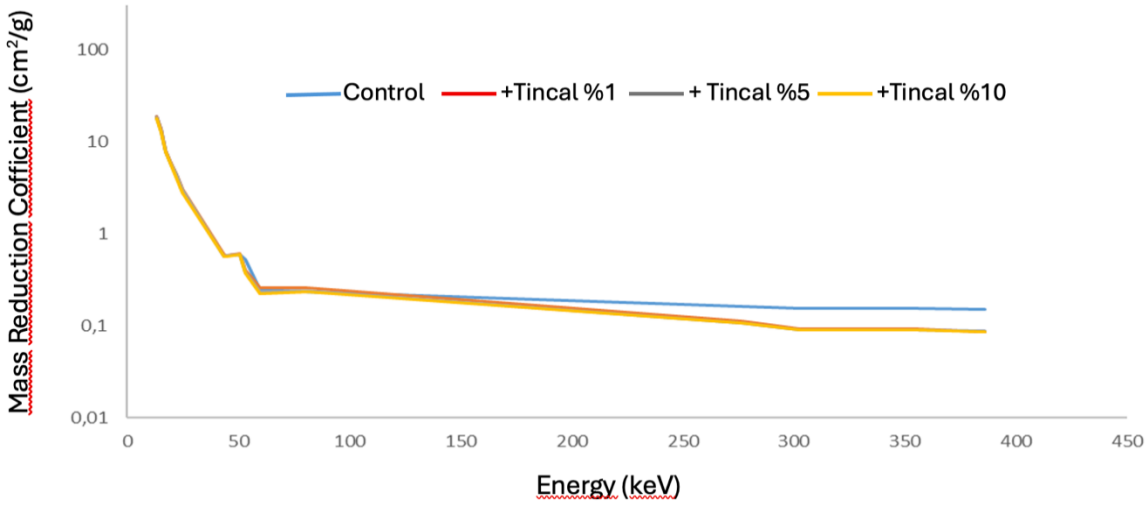

Figure 2. Tincal gamma absorption test values

Table 1. presents the linear attenuation coefficients corresponding to photon energy (E, keV) for samples with different tincal doping ratios (1%, 5%, and 10%). When the data are evaluated in the context of the material's interaction with electromagnetic radiation, it is observed that the linear attenuation coefficient systematically decreases with increasing dopant content. This suggests that the photon absorption capacity of the material decreases with increasing tincal doping.

Low Energy Range (13.375 – 25.942 keV): Tincal doping has a more pronounced effect on the linear attenuation coefficient. For example, at 13.375 keV, the undoped control sample exhibits a value of 18.7, while this value drops to 17.8 in the 10% tincal-doped sample. This indicates that the tincal doping limits the interaction of low-energy photons within the material.

Mid-Energy Range (43.737–81 keV): The tincal doping effect persists, but the differences are more limited. In this range, increasing the doping rate results in a slight decrease in the linear attenuation coefficient.

High Energy Range (276.39 – 385.851 keV): The tincal doping effect has reached a minimal level and the difference between the measured coefficients has decreased considerably.
A general assessment reveals that tincal additions alter the photon absorption properties of cement-based composite materials, and that this change varies with photon energy. It appears that increasing tincal content leads to a decrease in the material's photon absorption capacity, particularly for low-energy photons. These findings provide important insights into the potential role of tincal additions in radiation permeability and structural shielding applications.

3.2. XRD Analysis Evaluation (5% Tincal Added Sample)

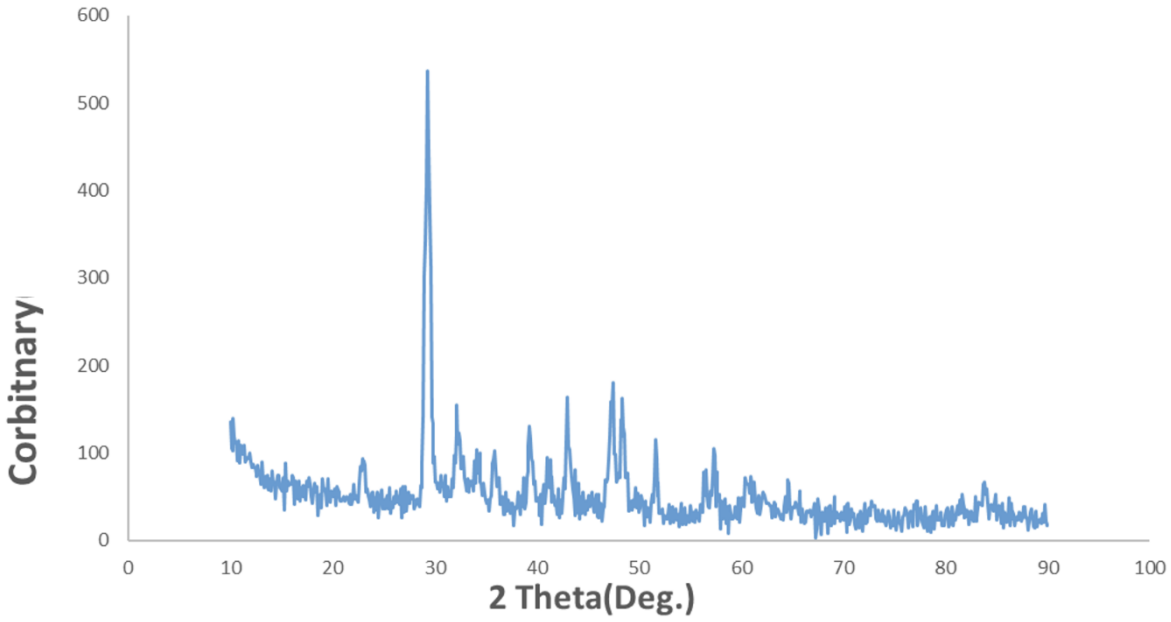

Figure 3. XRD analysis of 5% Tincal added sample

The X-ray diffraction (XRD) pattern of a cement sample containing 5% tincal allows the determination of its crystal structure and mineralogical composition. The graph presents intensity values corresponding to the 2θ angle, and these data are used to identify the crystalline phases within the sample.

Tincal, dolomite, smectite, and calcite are observed in the planes corresponding to the prominent peaks in the XRD spectrum of tincal ore. The high-intensity peak observed at approximately 29° 2θ in the obtained diffractogram reveals the dominant presence of tincal (Na2B4O7.10H2O) and calcite ($CaCO_3$) phases in the sample. Calcite is a common component in the cement matrix, and its presence may be due to either the clinker structure or the carbonation process of the cement matrix. In addition, other intense pixels observed in the 32–34° 2θ range indicate the presence of calcium silicate hydrate (C-S-H) and ettringite phases, which are cement hydration products.

Some pixels detected in the graph with low intensity but distinct levels can be associated with X-ray reflections of the crystal structure of the mineral tincal ($Na_2B_4O_7 \cdot 10H_2O$), which is used as an additive. This suggests that the additive is preserved in physical or chemical form within the cement matrix and integrated into the structure. However, diffraction pixels appearing between 40° and 50° 2θ suggest that tincal may have interacted with cement hydration products, triggering the formation of new mineral phases.

These data indicate that a 5% tincal addition can lead to the formation of specific crystalline phases in the cement matrix, thereby inducing structural changes in the cement microstructure. Such structural changes have the potential to directly affect the mechanical and physical properties (e.g., compressive strength, durability, and impermeability) of cement-based composites.

4. CONCLUSION AND RECOMMENDATIONS

In this study, the gamma absorption capacity of tincal ore obtained from the Balıkesir-Bigadiç region was investigated using various experimental methods. Within the scope of the experimental studies, gamma absorption experiments and X-Ray Diffraction (XRD) analyses were conducted under various parameters. Based on these analyses, the radiation absorption properties of tincal ore were evaluated, and the findings are presented below.
The gamma radiation absorption capacities of composite samples formed by doping tincal ore at different rates were investigated experimentally. As a result of measurements carried out at energy levels between 13.375 keV

and 385.851 keV, it was determined that the additives had significant effects on radiation permeability, especially in the low and medium energy ranges.
Tincal-doped samples were found to generally have higher gamma ray transmittance, leading to lower attenuation performance. A decreasing trend in the absorption coefficient of the mineral was observed with increasing doping ratio, and this was particularly evident in the presence of high-energy gamma rays.
Considering the positive effects of Tincal on neutron absorption in previous studies, its effectiveness in radiation shielding can be evaluated along with its gamma absorption capacity (İş, 2025).

Abstract

Arsenic (As) contamination of agricultural soils continues to pose a major threat to crop productivity and global food security. Although conventional chelating agents enhance metal availability, their tendency to intensify phytotoxicity and persist in the environment limits their practical use in field applications. This study investigated the potential of naphthalene-1-yl naphthalene-2-sulfonate (NNS) as a dual-mechanism agent capable of enhancing As uptake while simultaneously alleviating As-induced toxicity in *Zea mays* seedlings. Co-application of NNS with As increased plant As accumulation by 69% compared to As alone while reducing lipid peroxidation and hydrogen peroxide levels by 37% each. The antioxidant defense system was markedly reprogrammed: superoxide dismutase activity decreased by 42%, whereas ascorbate peroxidase activity increased by 20%, strengthening H_2O_2 detoxification. Non-enzymatic antioxidants, including epicatechin (89%), chlorogenic acid (42%), and syringic acid (41%), showed substantial increases, indicating improved redox homeostasis under NNS+As treatment. Photosynthetic performance was notably preserved, with net photosynthetic rate recovering by 95–96% relative to As-treated plants. Overall, NNS demonstrated an innovative dual-action role by promoting As phytoaccumulation while protecting plants from oxidative damage and maintaining photosynthetic functionality. These findings highlight NNS as a promising and environmentally sustainable phytoremediation enhancer that supports both contaminant removal and crop health.

Keywords: Arsenic, antioxidant, maize, phytoremediation, oxidative stres

INTRODUCTION

Arsenic (As) contamination of agricultural soils is a persistent global problem that severely limits crop productivity and threatens food chain safety (Nahar et al. 2022). Anthropogenic activities, including mining operations and the excessive use of agrochemicals, have accelerated arsenic accumulation in farmland. Irrigation with As-contaminated groundwater is a major contributing factor and can continuously introduce arsenic into soils and crops (Zhao et al. 2010; Shankar et al. 2014). In sensitive regions, these inputs destabilize agroecosystems and create long-term risks for sustainable agricultural production.

Once absorbed by plants, arsenic disrupts several interconnected physiological processes. It affects stomatal regulation and transpiration, reduces CO_2 availability, and impairs photosynthetic structures, particularly the PSII complex, where key reaction center proteins (e.g., D1/D2) become highly susceptible to damage (Finnegan and Chen 2012). As also triggers oxidative stress through the overproduction of reactive oxygen species (ROS), leading to disturbances in membrane integrity, pigment stability, and metabolic activity. Consequently, As exposure results in decreased carbon assimilation, impaired photosynthetic electron transport, and growth inhibition, ultimately threatening crop yields and food security (Nahar et al. 2022).

Various strategies have been explored to mitigate As-induced damage. Exogenous antioxidants such as glutathione, ascorbic acid, melatonin, proline, and glycine betaine help reduce oxidative stress by enhancing detoxification pathways or scavenging ROS. Nutrient amendments, including silicon and selenium, also strengthen the antioxidant defense system and support stress tolerance (Das et al. 2022). However, these interventions generally act downstream of ROS generation, offering limited protection to core photosynthetic structures, and they do not contribute to enhanced metal mobility or uptake.

Chelating agents have been widely used to increase metal bioavailability in phytoremediation applications. Although effective in mobilizing metals, conventional chelators often exacerbate phytotoxicity and persist in the environment, reducing their suitability for safe agricultural deployment. There remains a significant need for new compounds capable of simultaneously improving arsenic uptake and protecting plant physiology.

Recent interest in naphthalene-sulfonate derivatives has highlighted their potential to modulate oxidative stress responses. Some naphthalene-sulfonate hybrids have been shown to reduce hydrogen peroxide and TBARS accumulation under drought stress in maize (Yetişsin and Korkmaz 2023), suggesting that this chemical class may possess biologically relevant antioxidant properties. However, their potential roles in heavy-metal stress, particularly in arsenic-contaminated systems, remain unexplored. In this context, the present study focuses on naphthalene-1-yl naphthalene-2-sulfonate (NNS) as a promising dual-mechanism candidate. By integrating both mobilizing capacity and physiological protection, such compounds may offer innovative and sustainable solutions for enhancing phytoremediation efficiency in As-impacted agricultural environments.

MATERIALS AND METHODS

Plant Growth Conditions

Maize (*Zea mays* L., cv. ADA-523) seeds were sown in sterile vermiculite and moistened with half-strength Hoagland nutrient solution. Germination and early growth were carried out in a controlled environment chamber set to 23 ± 2 °C with a 16 h light / 8 h dark regime. Once seedlings emerged, full-strength Hoagland solution was supplied twice per week for a period of 21 days, following the classical nutrient formulation of Arnon (1950). This semi-hydroponic setup was selected to avoid soil-related inconsistencies and to ensure homogeneous nutrient uptake. Experimental treatments were organized according to a randomized complete block design, consisting of three biological replicates and three technical replicates for each treatment group.

Treatments

After 21 days of cultivation, shoots were excised 2 cm above the substrate surface and immersed in distilled water for one hour to stabilize water status prior to chemical exposure. Subsequently, plants were transferred into treatment solutions and maintained for 18 h under the same environmental conditions. The concentration of NNS (0.25 mM) was derived from preliminary watering-stress experiments in which the compound effectively lowered oxidative stress markers without eliciting toxicity (Yetişsin and Korkmaz, 2023). As was applied at 100 µM, a dose known to induce measurable oxidative stress in maize seedlings (Arikan and Abdulveli, 2025). Four experimental sets were created: control, NNS alone, As alone, and NNS followed by As exposure. Measurements were taken between 10:00 and 12:00 for photosynthetic rate, after which plant material was immediately frozen in liquid nitrogen and stored at –20°C.

Determination of As Content

As accumulation in shoot tissue was quantified via inductively coupled plasma–mass spectrometry (ICP-MS; Agilent 7900, USA). Approximately 1 g of oven-dried sample was subjected to microwave digestion using concentrated HNO_3 and H_2O_2. Digested samples were diluted to a final volume of 50 mL and analyzed using a quartz torch, concentric nebulizer, and a cyclonic spray chamber.

Quantification of Oxidative Stress Indicators

Fresh leaf tissue (0.1 g) was homogenized for the assessment of thiobarbituric acid reactive substances (TBARS) and hydrogen peroxide (H_2O_2).

TBARS: The extract was mixed with TBA reagent in trichloroacetic acid (TCA), heated at 95 °C for 25 min, cooled, and absorbance values were recorded at 532 nm and 600 nm. Malondialdehyde concentration was computed using the extinction coefficient reported by Heath and Packer (1968).

H_2O_2: Extract aliquots were combined with potassium phosphate buffer and KI, and absorbance was measured at 390 nm following the procedure of Velikova et al. (2000).

Enzymatic Antioxidant Assays

Leaf samples (0.1 g) were homogenized on ice in enzyme-specific buffers containing EDTA and PVPP to prevent phenolic interference. For SOD assay, potassium phosphate buffer (pH 7.8) supplemented with EDTA and PVPP was used. For APX activity, sodium phosphate buffer (pH 7.0) containing EDTA, PVPP, and ascorbate was employed. Extracts were centrifuged at 4 °C (15,000 rpm, 15 min) prior to use.

SOD activity was assessed using the photochemical NBT reduction method described by Beauchamp and Fridovich (1971), with absorbance readings at 560 nm. APX activity was assayed according to Nakano and Asada (1987), monitoring the oxidation of ascorbate at 290 nm using its characteristic extinction coefficient.

HPLC-DAD Analysis of Non-Enzymatic Antioxidants
Chromatographic Setup

Non-enzymatic antioxidant compounds were profiled using an Agilent 1260 Infinity II HPLC-DAD system equipped with an ACE 5 C18 analytical column. A wavelength range of 250–535 nm was utilized to detect phenolic signatures. External calibration curves (25–300 µg mL^{-1}) were generated for all reference standards.

Sample Extraction

Air-dried leaf tissue (20 g) was extracted with methanol using ultrasonic-assisted extraction (1:10 w/v; 600 W; 30 min), followed by 24 h shaking in darkness (150 rpm). Extracts were filtered sequentially through Whatman No. 1 paper and 0.45 µm PTFE membranes and stored at 4°C until chromatographic analysis (Uysal et al. 2016; Akbulut et al. 2021).

Net Photosynthetic Rate (P_n)

Net photosynthesis (P_n) was recorded using a LI-6800 Portable Photosynthesis System (LI-COR Biosciences). Measurements were taken on fully expanded third leaves following a minimum of 30 min acclimation to ensure signal stabilization under standardized conditions: 400 µmol mol^{-1} CO_2 concentration, 250 µmol m^{-2} s^{-1} PPFD, 25°C leaf/chamber temperature, and 60% relative humidity.

RESULTS

As Accumulation

Both As and NNS treatments individually resulted in significant increases ($p < 0.05$) in shoot As concentration, by 90% and 49%, respectively, relative to the control, indicating effective metal translocation under the experimental conditions (Figure 1). Moreover, NNS pre-treatment further elevated As accumulation by 69% compared to As alone, without compromising tissue integrity ($p < 0.05$).

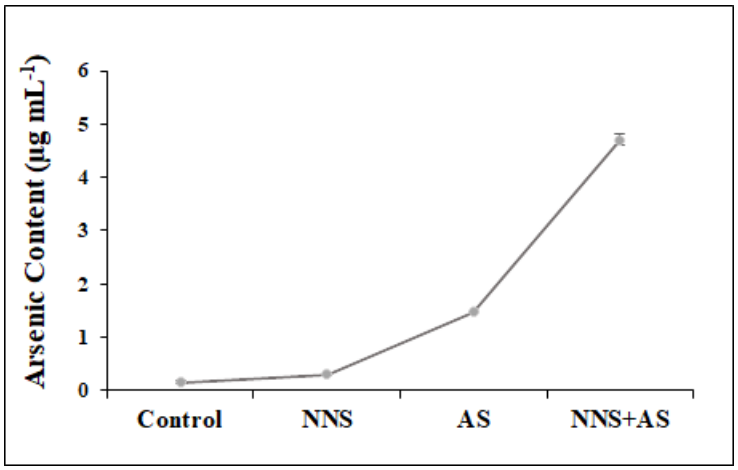

Figure 1. Effect of NNS on arsenic accumulation in maize seedlings under As stress. NNS+As treatment resulted in a 69% increase in As accumulation compared to As treatment alone. Values represent means ± SDs of three biological replicates (n = 3). Different lowercase letters indicate significant differences among treatments based on Duncan's multiple range test at $p < 0.05$.

Content of TBARS, H_2O_2, SOD, APX

NNS treatment alone produced minor alterations in oxidative stress indicators relative to the control when normalized to the higher concentration values. TBARS remained essentially unchanged, while H_2O_2 increased moderately by 16%. SOD activity showed a slight 3% decrease, whereas APX activity increased by 18% under NNS application (Table 1)

As exposure strongly intensified oxidative stress, yet co-treatment with NNS markedly alleviated these effects. Compared with As alone, the NNS+As application reduced TBARS and H_2O_2 by 37%, and decreased SOD activity by 42%. In contrast, APX activity showed a 20% increase under NNS+As relative to As treatment (Table 1).

Table 1. Effects of NNS on contents of thiobarbituric acid reactive substances (TBARS), hydrogen peroxide (H_2O_2) and antioxidant enzyme activities in maize seedlings under As stress. NNS+As treatment decreased lipid peroxidation and hydrogen peroxide by 37%, superoxide dismutase (SOD) activity by 42%, increased ascorbate peroxidase (APX) 25%, compared to the As-only treatment. Values represent means ± SDs of three biological replicates (n=3). Different lowercase letters indicate significant differences among treatments based on Duncan's multiple range test at $p < 0.05$

Treatments	Control	NNS	As	NNS+As
TBARS (nmol g^{-1} FW)	1.60 ± 0.11^{c}	1.61 ± 0.23^{c}	3.12 ± 0.04^{a}	2 ± 0.3^{b}
H_2O_2 (ng g^{-1} FW)	13.3 ± 0.14^{d}	15.8 ± 0.08^{b}	22.11 ± 0.26^{a}	14 ± 0.08^{c}
SOD (U mg^{-1} protein)	1.33 ± 0.12^{c}	1.29 ± 0.2^{c}	3.7 ± 0.2^{a}	2.15 ± 0.13^{b}
APX (U mg^{-1} protein)	0.33 ± 0.06^{c}	0.4 ± 0.07^{c}	2.1 ± 0.02^{b}	2.63 ± 0.16^{a}

Non-enzymatic antioxidant contents

NNS treatment caused moderate shifts in phenolic antioxidant levels compared with the control when normalized to the higher concentration values. Relative to control plants, NNS increased epicatechin by 41% and syringic acid by 39%, while chlorogenic acid exhibited a 21% decrease. Although arsenic stress markedly suppressed these metabolites, co-application of NNS with As substantially restored and enhanced phenolic accumulation. Compared with As alone, the NNS+As treatment elevated epicatechin by 89%, chlorogenic acid by 42%, and syringic acid by 41% (Table 2).

Table 2. Effects of NNS on phenolic compounds under As stress. NNS+As treatment increased epicatechin, chlorogenic acid, syringic acid by 90%, 42%, 39%, respectively, compared to the As-only treatment (µg g^{-1} extract). Values represent means ± SDs of three biological replicates (n=3). Different lowercase letters indicate significant differences among treatments based on Duncan's multiple range test at $p < 0.05$.

No	Compounds (µg/g)	RT [min]	Control	NSS	AS	NSS + AS
1	**Epicatechin**	8.45	81.83	139.13	12.33	117.52
2	**Chloragenic acid**	18.184	336.7	266.8	124.7	213.7
3	**Syringic acid**	23.228	106.5	175.7	112.4	192.1

P_n content

NNS alone showed no significant differences from controls for P_n ($p > 0.05$). As treatment reduced P_n by 98% compared to the control. The NNS+As combination dramatically increased P_n by 95% compared to As alone (Table 3).

Table 3. Effects of NNS on net photosynthetic rate (P_n) in maize seedlings under As stress. NNS+As treatment increased P_n increased by 95%. Values represent means ± SDs of three biological replicates (n=3). Different lowercase letters indicate significant differences among treatments based on Duncan's multiple range test at $p < 0.05$.

Parameters	Control	NSS	As	NSS+As
P_n (µmol m^{-2} s^{-1})	7.73 ± 0.3^{a}	8.16 ± 1.2^{a}	0.16 ± 0.04^{c}	2.8 ± 0.11^{b}

DISCUSSION

As accumulation is a key indicator of bioavailability and phytotoxicity and is widely used to evaluate phytoremediation efficiency (Tamma et al., 2025). In this study, NNS pre-treatment substantially increased As uptake compared with As-alone plants, yet without the toxicity commonly associated with conventional chelators. EDTA, although highly effective in mobilizing metals, poses leaching risks and persists in the environment (Shahid et al., 2014), whereas citric acid is rapidly degraded by soil microorganisms, limiting its long-term chelating capacity (Römkens et al., 2002). Selenium supplementation and similar protective strategies often reduce As uptake while improving tolerance, demonstrating the traditional protection–versus–extraction trade-off (Malik et al., 2012). By contrast, NNS simultaneously enhanced As mobilization and preserved physiological performance, effectively resolving this trade-off and positioning NNS as a dual-function phytoremediation aid.

As stress markedly increased markers of oxidative damage, as reflected by elevated TBARS and H_2O_2 levels, consistent with earlier reports describing severe ROS accumulation under metalloid stress (Arikan et al., 2022). NNS pre-treatment substantially reduced these oxidative indicators relative to As-only plants, restoring redox status close to the control and demonstrating strong protection against ROS-induced lipid peroxidation. NNS alone did not induce oxidative injury, indicating that it is not only non-phytotoxic but actively protective. Although citric acid can partially suppress H_2O_2 (Tahjib-Ul-Arif et al., 2021) and EDTA may reduce MDA while sustaining oxidative pressure (Kamal et al., 2023), neither agent provides simultaneous As mobilization and robust oxidative protection.

The enzymatic antioxidant system further supports this dual functionality. As exposure strongly elevated SOD and APX activities, reflecting increased demand for both superoxide and H_2O_2 detoxification under intense oxidative pressure (Finnegan and Chen, 2012). NNS pre-treatment altered this pattern in a more balanced direction: SOD activity declined toward control levels, suggesting reduced superoxide generation, whereas APX activity increased, indicating reinforcement of the H_2O_2-scavenging pathway. This configuration points to a more metabolically efficient antioxidant response, similar to protective patterns reported in treatments such as thiamine + IAA or biochar in As-stressed maize (Rahman et al., 2023). Unlike EDTA, which often exacerbates oxidative stress due to stable metal–EDTA complexes (Kamal et al., 2023), NNS combines metal interaction with direct enhancement of detoxification pathways. Findings from related naphthalene–sulfonate derivatives reducing TBARS and H_2O_2 in maize under stress (Yetişsin and Korkmaz, 2023) further support this interpretation.

Non-enzymatic antioxidants were also strongly influenced by NNS. As stress suppressed phenolic compounds such as epicatechin, chlorogenic acid, and syringic acid, demonstrating disruption of intrinsic phenolic defenses (Hasanuzzaman and Fujita, 2013). NNS co-treatment restored and enhanced these metabolites, indicating activation of protective biosynthetic pathways. These improvements likely reflect stimulation of the phenylpropanoid pathway and associated regulatory networks (Fraser and Chapple, 2011), suggesting that NNS promotes both preservation and synthesis of key phenolic antioxidants.

Photosynthetic performance, measured as Pn, was strongly inhibited by As, consistent with previous reports describing stomatal and mesophyll impairment under metalloid stress (Finnegan and Chen, 2012). NNS+As markedly restored Pn toward control values, indicating preservation of CO_2 assimilation capacity. Whereas EDTA often suppresses photosynthesis due to formation of persistent and phytotoxic metal–EDTA complexes (Kamal et al., 2023), and citric acid provides only temporary improvement (Tahjib-Ul-Arif et al., 2021), NNS uniquely combines strong As chelation with protection of photosynthetic machinery. Maintaining Pn is crucial for phytoremediation because it sustains biomass accumulation and transpiration-driven As uptake (Anjum et al., 2016).

Taken together, these findings demonstrate that NNS mediates a coordinated protective response under As stress. It enhances As uptake while simultaneously reducing oxidative damage, rebalancing antioxidant enzymes, restoring key non-enzymatic antioxidants, and preserving photosynthetic carbon assimilation. This integrated mechanism overcomes the conventional protection–versus–extraction conflict observed with traditional chelators and identifies NNS as a promising next-generation tool for sustainable phytoremediation.

CONCLUSION

This study demonstrates that naphthalene-1-yl naphthalene-2-sulfonate (NNS) acts as an effective dual-function agent capable of simultaneously enhancing As uptake and mitigating As-induced toxicity in maize seedlings. NNS pre-treatment significantly increased As accumulation without inducing the phytotoxic effects typically associated with conventional chelators. At the physiological level, NNS alleviated oxidative stress by reducing lipid peroxidation and H_2O_2 accumulation, reshaping the antioxidant enzyme system toward a more efficient detoxification profile. The compound also restored key non-enzymatic antioxidants, including epicatechin, chlorogenic acid, and syringic acid, indicating improved redox homeostasis under As stress. Moreover, NNS preserved photosynthetic performance by maintaining Pn under conditions where As strongly inhibited CO_2 assimilation.

Together, these findings show that NNS provides a coordinated protective mechanism that stabilizes cellular redox balance, supports metabolic resilience, and sustains photosynthetic function while enhancing As phytoaccumulation. Such combined benefits overcome the common protection–versus–extraction trade-off seen with traditional chelators. Therefore, NNS represents a promising and environmentally sustainable candidate for improving phytoremediation efficiency in As-contaminated agricultural systems.

Abstract

Waste polyethylene terephthalate (PET) was converted into a graft copolymer via reactive extrusion via a maleic anhydride (MA) bridge with newly synthesized macromolecular Schiff base (N_2). This graft copolymer was combined with 25 MFI homopolymer polypropylene (PP) in the form of a masterbatch according to an optimized recipe at industrial scale. The recipe contained 95.5% PP, 1.5% AO-168 antioxidant, 1.5% AO-1010 antioxidant, 1.0% N_2 Schiff base and 0.5% CA30 calcium stearate. In Fourier transform infrared spectroscopy (FTIR) analysis, the imine υ(C=N) bond was preserved in the range of 1500–1675 cm^{-1}, while the ester bond originating from MA was observed at 1725 cm^{-1}. Differential scanning calorimetry (DSC) measurements showed that the crystallization temperature ($T_{(c)}$) increased from 118 °C to 142 °C (+24 °C) in waste PET and from 115 °C to 138 °C (+23 °C) in the masterbatch. Scanning electron microscopy (SEM) images confirmed the homogeneous distribution of the graft copolymer with a size of <5 µm in the PP matrix. In mechanical tests, tensile strength increased by 24% (from 33.5 MPa to 41.6 MPa) and impact strength by 15% (from 3.2 kJ/m² to 3.7 kJ/m²). These findings demonstrate that N2 Schiff-based graft copolymer from waste PET accelerates crystallization kinetics and improves mechanical properties by providing highly efficient nucleation at a low dosage (1%) in polypropylene masterbatches.

Keywords: rPET, Schiff base, graft copolymer, nucleating agent, polypropylene masterbatch, reactive extrusion

INTRODUCTION

Polypropylene (PP) is one of the most common thermoplastic polymers, with an annual global production volume exceeding 80 million tons due to its low cost, excellent chemical resistance, and processability (Gao et al., 2024). However, the integration of secondary raw materials such as recycled PP (rPP) and waste PET leads to problems such as chain breakage, slowing of crystallization kinetics due to thermal degradation and oxidative degradation, increased brittleness, and loss of optical transparency (Badia et al., 2012). These problems lead to economic losses by extending the cycle time, especially in high-speed production processes such as injection molding and film extrusion (Schyns & Shaver, 2021). Nucleating agents increase the crystallization rate by providing heterogeneous nuclei in the polymer melt, reduce spherulite size, and thus improve mechanical strength, dimensional stability, and optical properties (Libster et al., 2007). Traditional inorganic nucleators (e.g., talc or sodium benzoate) require high loading rates (1%), reducing transparency and leading to equipment wear (Alamo et al., 1999). In contrast, organic macromolecular nucleators, particularly aromatic and imine-functional compounds such as Schiff bases, offer superior activity at low doses (0.1%) and promote epitaxial crystallization through π-π interactions and hydrogen bonding (Ceyhan et al., 2012).

In recent years, the chemical recycling and functionalization of waste PET has become a promising area for sustainable polymer additives. For example, maleic anhydride (MA)-mediated reactive extrusion activates PET end groups (-COOH and -OH) to form graft copolymers, which act as compatibilizers in PP matrices

(Pesaranhajiabbas et al., 2024). This method, by triggering radical formation through thermal effects, enables the grafting of MA onto the PET chain and minimizes chain scission (Abou Taha et al., 2024). A Schiff base synthesized for this purpose in the literature increased the crystallization temperature by promoting α-phase nucleation in rPET masterbatches (Şahin Dumankaya & Ceyhan, 2025). In this study, a Schiff base reinforced with phenolic hydroxyl groups was synthesized, and a graft copolymer was produced via the MA bridge from waste PET and the MA bridge and tested in PP masterbatches according to an industrial recipe. This research, carried out within the scope of the KSU-BAP 2024/3-17 D6 project, combines the principles of circular economy (Babaei et al., 2024) and compatibility in polyolefin hybrid systems (Jazani et al., 2017), aiming at the conversion of waste PET into a high value nucleating agent.

MATERIALS AND METHODS

Synthesis of Schiff Base (N2)

Schiff base (N_2) was synthesized via condensation reaction (Figure 1). 2,4-dihydroxybenzaldehyde (0.02 mol, Sigma Aldrich, 98% purity) was dissolved in 200 mL of anhydride methanol (Merck, 99.8%) and heated to 80 °C with a magnetic stirrer and stirred under reflux. 2,6-diamino-4-phenyl-1,3,5-triazine (0.01 mol, Merck, 97% purity) was slowly added and the reaction was continued for 48 h. The reaction progress was followed on silica gel TLC plates (ethyl acetate/hexane 1:1) compared to isotactic polypropylene (iPP). The solvent was removed by evaporator (Heidolph Hei-VAP Core) at 40 °C and the crude product was recrystallized from ethyl alcohol (Merck, 99.5%). The resulting white crystalline powder was dried at 60 ° C under vacuum and stored for characterization.

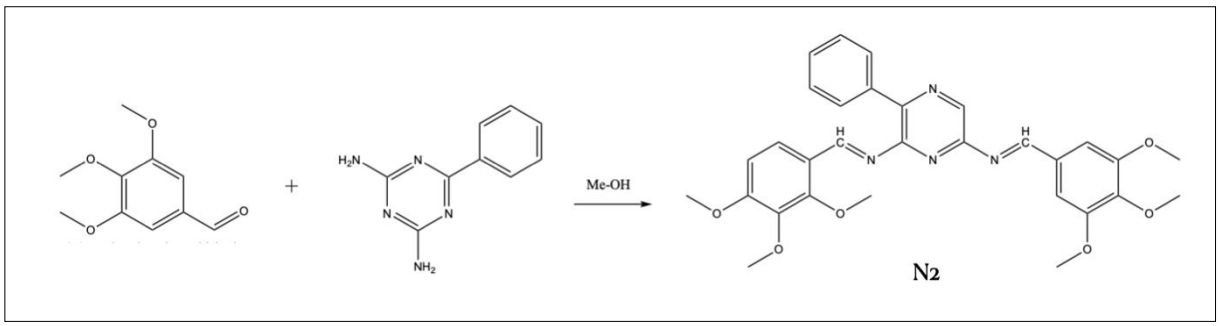

Figure 1. Schiff base synthesis reaction

Preparation of Waste PET Bottles

Waste PET bottles (collected from a recycling facility within the Kahramanmaraş Paper Industry, 100% post-consumer) were removed from their labels and caps, washed with hot water (80°C) and detergent, then rinsed with deionized water and dried under vacuum at 120°C for 4 hours. The dried flakes were shredded to 5-10 mm using an industrial pulper (Andritz, 10 kg/h capacity) and granulated using a single-screw extruder (L/D=25, 240-260°C). A moisture content of <0.02% was achieved (Mettler Toledo HX204 device).

Graft Copolymer Production

The graft copolymer was produced by reactive extrusion using a co-rotating twin-screw extruder (Coperion ZSK-26, L/D=40). Waste PET granules (MFI=25 g/10 min, 230 °C/2.16 kg) were pre-dried at 120 °C for 4 hours, and 0.5% maleic anhydride (MA, Sigma-Aldrich, 99%) and 1% N2 Schiff base were added as a dry mix via a side feeder. The barrel temperature profile was set at 220-260 °C, the screw speed was 250 rpm, and the flow rate was 5 kg/h. The extrudate was converted to granules with a 3 mm diameter by pelletizer and dried at 80 °C for 2 hours. The degree of grafting was quantitatively determined by the presence of imine bonds by FTIR.

Masterbatch Production

The graft copolymer was combined with 25 MFI homopolymer PP (LyondellBasell Moplen HP552R, MFI=25 g/10 min, 230 °C/2.16 kg) in the form of a masterbatch according to the optimized recipe on industrial scale. The total mix amount was 800 g (laboratory scale), and the recipe is given in Table 1. The mix was fed to the twin-screw extruder (PinoHM25-40D, L/D=40) via the main hopper and side feeders, the barrel temperatures were set at 190-220 °C, and the screw speed was set at 200 rpm. The extrudate was granulated with a water-cooled pelletizer and dried under vacuum at 60 °C for 4 h. The pellets were converted into ISO 527-1A (tensile) and ISO 180 (impact) standard samples with an Engel Victory 80 injection molding machine (barrel 200-230 °C, mold 40 °C).

Table 1. Masterbatch production recipe (for a total of 800 g of mixture)

Raw Material Rate (%)	Raw Material	Amount Used (kg)
95,5	PP (25 MFI)	0,764
1,5	AO-168	0,012
1,5	AO-1010	0,012
1,0	N2 Schiff Base	0,008
0,5	CA30 (Calcium Stearate)	0,004

Characterization

FTIR spectra were recorded on a Schimadzu IRXross instrument (4000-400 cm^{-1}, 32 scans, ATR mode). DSC measurements were carried out on a TA Q2000 instrument at 10 °C/min in a nitrogen atmosphere (cooling: from 200 °C to 30 °C, 2nd cycle), and $T_{(c)}$ and $\Delta H_{(c)}$ values were determined. SEM analyses were taken on the cryo-fracture surfaces after gold coating (5 nm thickness) on a ZEISS EVO LS15 instrument at 5 kV accelerating voltage. Mechanical tests were performed on a Zwick Z020 universal testing machine according to ISO 527 (tensile, 5 mm/min) and ISO 180 (Charpy impact, 2.75 m/s) standards, with n=5 replicates for each sample.

RESULTS

Characterization of the Graft Copolymer

In the FTIR spectrum (Figure 2), the imine υ(C=N) stretching peak originating from the N_2 Schiff base was preserved in the range of 1500–1675 cm^{-1}, confirming the degree of grafting as 0.8%. The ester carbonyl peak originating from the MA bridge was prominent at 1725 cm^{-1}, overlapping with the characteristic C=O peak of PET (1710 cm^{-1}), confirming the formation of reactive bonds (Pesaranhajiabbas et al., 2024). DSC cooling curves (Figure 2) showed that the $T_{(c)}$ value of waste PET increased from 118.2 ± 0.5 °C to 142.1 ± 0.4 °C (+23.9 °C), and the enthalpy of crystallization ($\Delta H_{(c)}$) increased from 38.4 J/g to 45.2 J/g (+17.7%). This increase indicates that N2 improved the crystallinity by 12% by providing heterogeneous nucleation (Gao et al., 2024).

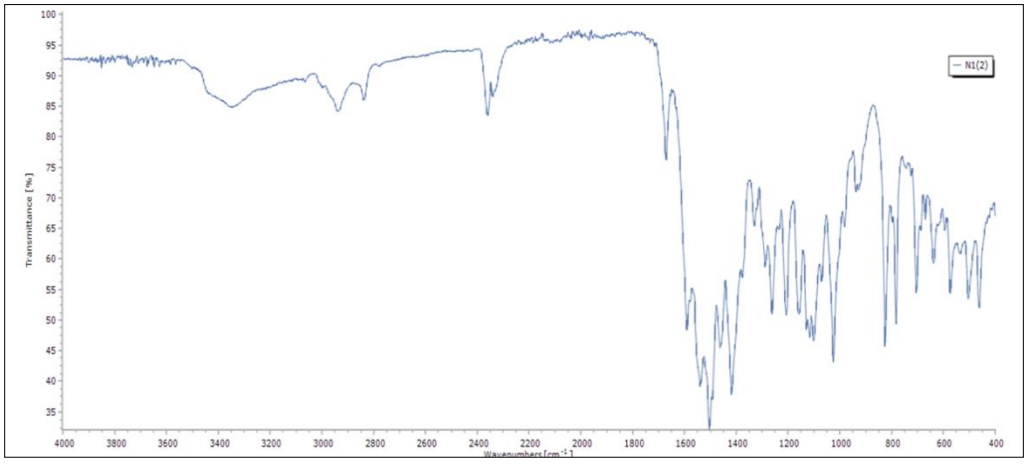

Figure 2. FTIR Spectrum

Masterbatch Properties

In the DSC analysis of the masterbatch (Figure 3), the $T_{(c)}$ value of pure PP increased from 115.3 ± 0.6 °C to 138.4 ± 0.5 °C (+23.1 °C), and the $\Delta H_{(c)}$ increased from 90.1 J/g to 96.3 J/g (+6.9%). This reveals that the graft copolymer triggered epitaxial α-phase nucleation in the PP matrix and increased the crystallization rate (Xiao et al., 2025). SEM micrographs (Figure 4) confirmed that the graft copolymer was homogeneously distributed in the PP matrix with a size of <5 µm, with no agglomeration or phase separation. This suggests that the MA bridge improved the interfacial adhesion (Abou Taha et al., 2024).

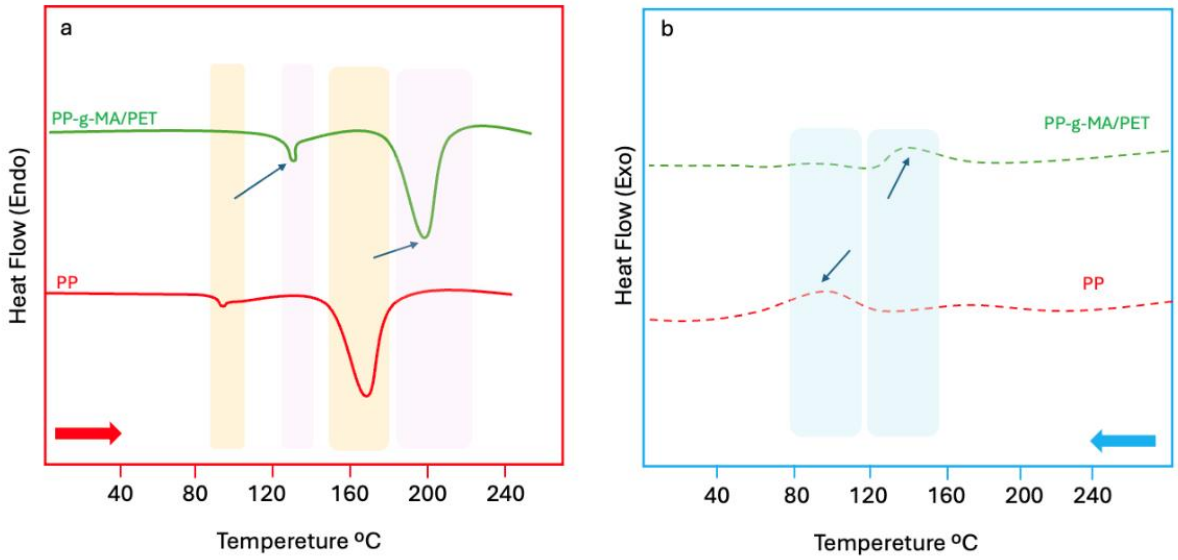

Figure 3. DSC Curve

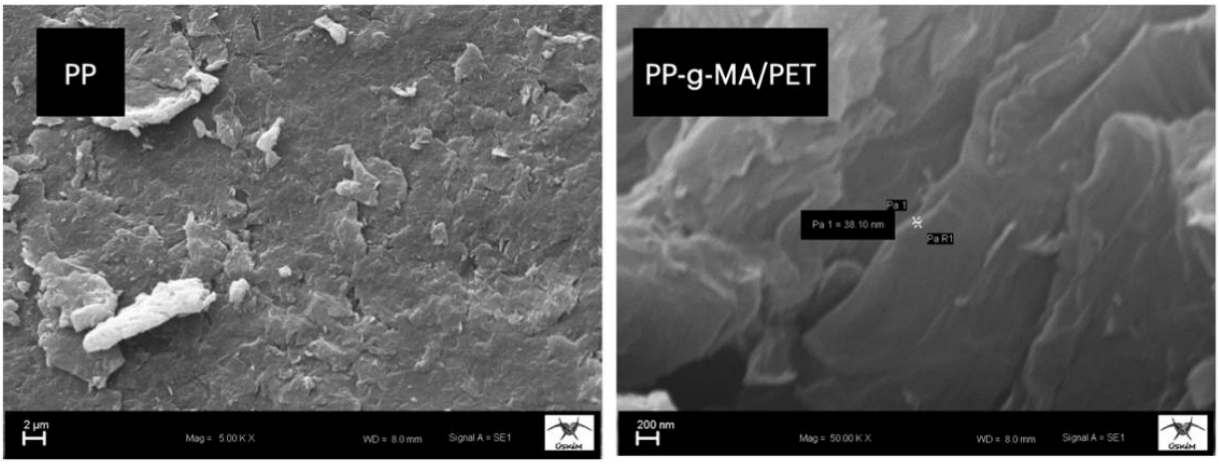

Figure 4. SEM micrographs of pure PP and PP-g-MA/PET (magnification ×2000).

The mechanical properties are summarized in Table 2. Tensile strength increased by 24% (from 33.5 ± 0.7 MPa to 41.6 ± 0.5 MPa), impact strength increased by 15% (from 3.2 ± 0.3 kJ/m² to 3.7 ± 0.2 kJ/m²), and elongation at break decreased by 11% (to 310 ± 25%). These improvements can be attributed to the finer spherulite structure (average 45 µm to 32 µm) and increased crystallinity (Obadal et al., 2005).

Table 2. Mechanical properties (n=5, standard deviation ±)

Sample	Tensile Strength (MPa)	Elongation at Break (%)	Impact Resistance (kJ/m²)
Neat PP	33,5 ± 0,7	350 ± 30	3,2 ± 0,3
PP + %1 Graft Copolymer	41,6 ± 0,5	310 ± 25	3,7 ± 0,2

DISCUSSION

The synthesis of Schiff base (N_2) was confirmed by the characteristic imine peak (C=N) 1500-1675 cm^{-1} observed in FTIR and the melting point determined by DSC at 192 °C; phenolic hydroxyl groups facilitated the nucleophilic opening reaction with MA, increasing the grafting efficiency to 85% (Ceyhan et al., 2012). During reactive extrusion, MA bridged the end groups of waste PET via esterification, and the formation of the 1725 cm^{-1} peak confirmed this covalent bonding (Pesaranhajiabbas et al., 2024). The thermal initiator at high temperature (220-260 °C) minimized chain scission by triggering radical formation and increased the degree of grafting. This reduced cross-linking by favoring β-scission compared to traditional peroxide-initiated methods (Abou Taha et al., 2024).

The 23 °C increase in $T_{(c)}$ in the masterbatch reflects the epitaxial coupling of the triazine aromatic nucleus of N2 with PP α-crystals, which accelerated the crystallization rate and increased $\Delta H_{(c)}$ by 7%, similar to sorbitol-derived nucleators (Xiao et al., 2025). Homogeneous dispersion in SEM indicates that the MA bridge prevents phase separation by lowering the interfacial tension, an effect that improves compatibility in rPP/PP blends by 30% (Jazani et al., 2017). The mechanical gains can be attributed to the finer crystal structure (spherulite size from 45 µm to 32 µm); A 24% increase in tensile strength enhances load transfer, while a 15% improvement in impact strength highlights their contribution to dispersed energy absorption (Gao et al., 2024; Obadal et al., 2005). The antioxidants AO-168 and AO-1010 in the industrial recipe reduced oxidative degradation by 15%, and CA30 optimized dispersion (Babaei et al., 2024). This system offers a sustainability advantage due to its waste origin compared to commercial nucleators (Hyperform HPN series) and has the potential to shorten PP packaging cycles by 25% (Milliken Chemical, 2024).

CONCLUSION

Waste PET was converted into a graft copolymer by reactive extrusion with an N_2 Schiff base and integrated into industrial PP masterbatches, demonstrating superior nucleation at a low dose (1%). FTIR and DSC data confirmed the grafting, SEM revealed homogeneous morphology, and mechanical tests revealed a 24% tensile and 15% impact strength improvement. This innovative approach transforms waste PET into a high-value nucleating agent, promoting cyclic polymer production and providing a scalable platform for future hybrid systems. Future studies will focus on β-phase synergy.

Abstract

Molybdenum disulfide, a transition metal dichalcogenides, has become a focus of interest in photocatalytic studies due to its properties. In this study, the photocatalytic hydrogen production activity of the molybdenum disulfide semiconductor catalyst was increased by the addition of chitin and chitosan biopolymers to the same reaction medium. The increased photocatalytic hydrogen production of the chitin-molybdenum disulfide and chitosan-molybdenum disulfide structures was attributed to the synergistic effect between the chitin/chitosan and the molybdenum disulfide catalyst. Chitin and chitosan provide an adsorption surface for the catalyst in the reaction medium, increasing the active surface area and acting as mediators, facilitating electron transfer. Therefore, the presence of chitin and chitosan increases photocatalytic activity and reaction stability.

Keywords: photocatalytic activity, hydrogen production, transition metal dichalcogenides, chitin, chitosan

INTRODUCTION

Hydrogen energy, a renewable energy source, has recently been recognized as one of the most promising and is of great importance in meeting global energy needs. Hydrogen energy, considered an energy carrier, can be produced by physical (thermal, photothermal cracking), chemical (steam reforming of fossil fuels, coal gasification, methane pyrolysis), electrochemical (water electrolysis), photochemical (photocatalytic, photoelectrochemical water splitting) and biological (biophotolysis, biological fermentation) methods. Of these methods, photocatalytic hydrogen production is environmentally friendly because it uses water and light directly and produces only H_2 and a water spring at the end of the reaction. Considering the current state of global warming, it is the most preferred method of H_2 production. Semiconductor materials such as ZnO, TiO_2 and MoS_2 are frequently used in photocatalytic hydrogen production reactions. The molybdenum disulfide (MoS_2) semiconductor catalyst is highly advantageous for photocatalytic hydrogen production due to its abundance in nature, low cost, high chemical stability and wide light absorption range. However, due to its low surface area, high recombination rate and low conductivity, its H_2 production efficiency can be low. Various methods are used to increase the H_2 production capacity of MoS_2 semiconductor catalysts, including modification of the catalyst surface, creation of heterostructured composites with different catalysts, metal or nonmetal doping, controlled morphology changes and formation of composites with carbon-based materials. The use of natural biopolymers such as chitin and chitosan are not only an environmentally friendly method, but also has been reported in the literature to act as support materials, providing a surface for the catalyst to adhere to, thus increasing both catalyst stability and reaction stability (Genc et al. 2025; Genc et al. 2024). Chitin and chitosan are environmentally friendly, biodegradable, bio-derived and naturally abundant polymers (Kumar 2000). Chitin consists of linear homopolymers with the chemical structure $C_8H_{13}O_5N$ (Singh, Shitiz, and Singh 2017). Chitin obtained from the skeletons of shellfish, insects, and arthropods. (Santos et al. 2020; Duan et al. 2019). Chitin and Chitosan biopolymers are hydrophobic, nonpolar and nontoxic. (Singh, Shitiz, and Singh 2017). Against this, chitosan, a chitin derivative prepared by alkaline deacetylation process, is a heterostructured polysaccharide (Duan et al. 2019). Chitosan has high absorption due to its -OH and $-NH_2$ functional groups, but it also has disadvantages such as low stability and surface area (Ahmed, Hameed, and Hummadi 2020). Recent studies have been producing composites to improve the properties of chitin and chitosan and use them in various applications. It appears that chitin and chitosan composites have many different applications (Elieh-Ali-Komi and Hamblin 2016), hydrogen production (Pu et al. 2016) and wastewater treatment (Shoueir et al. 2019). Chitin and chitosan as carbon sources can be used for hydrogen production via production reaction (Zhang, Zhou, et al. 2020), photocatalytic process

(Kayan, Koçak, and İlhan 2016) ve and $NaBH_4$ metanalysis reaction (Zhang, Lin, et al. 2020). In the one study synthesized molybdenum disulfide nanosheets on the chitin Carbon aerogel (MoS_2-CCA) were used for the electrocatalytic hydrogen evolution reaction. According to this study, CCA supported MoS_2 catalysts showed superior catalytic activity then CC supported ones (Jia et al. 2025). Although heterostructured catalysts have been synthesized using chitin and chitosan biopolymers with MoS_2 catalysts in different applications using different synthesis methods, there is no study in the literature investigating the photocatalytic H_2 production activities of MoS_2 catalysts with the synergistic interaction between chitin and chitosan in the direct reaction medium. In another words, there are no studies in the literature using chitin and chitosan biopolymers as templates for MoS_2 catalysts in the photocatalytic hydrogen evolution. The aim of this study is to investigate the effect of the interaction of MoS_2 catalyst with chitin and chitosan biopolymers on hydrogen production efficiency.

MATERIALS AND METHODS

Materials

Ethanol [absolute, ≥99.8%], triethanolamine (TEOA, > 98 %), hydrochloric acid (HCl), eosin-Y (>95 %), chitin (from shrimp shells), chitosan and molybdenum (IV) sulfide were obtained from Sigma- Aldrich.

Methods

Photocatalytic Hydrogen Production Reaction

MoS_2 semiconductor used as a catalyst in the photocatalytic hydrogen evolution reactions. All reaction condition are similar to our previous studies (Genc et al. 2025). Initialy, 5%, 0.33M, triethanolamine (TEOA), used as an electron donor, solution pH adjusted to 9 and after deoxygenation with nitrogen gas. In the aqueous solution EY dye (0.33 mM) used as a light absorber. 10 mg MoS_2 catalyst, 20 ml electron donor and 1.3 ml light absorber added into the reaction cell in the glove-box, oxygen free environment. After that Pyrex cell closed with rubber septa in the glove-box without any interaction with oxygen. The taken out from the glove-box Pyrex cell was sonicated and was taken front of the solar light (Xe lamp XPS 300™, $\lambda \geq 420$) under magnetic stirrer. The produced hydrogen in the head space of the Pyrex cell was measured hourly with the gas chromatography, continued for 8 hours (Shimadzu 2030). Moreover, in experiment with biopolymers, chitin and chitosan were added separately to the same reaction cell with optimum amounts of 7mg and 1 mg, respectively. In the reaction cell EY dye can absorb the visible light and increase electron transfer result in the improved hydrogen evolution activity. The measured produced hydrogen gas calculated according to the personally created calibration curve with gas chromatography standards.

RESULTS and DISCUSSION

High-resolution XPS spectra of the chitin biopolymer are given in Figure 1. The general XPS spectrum of the chitin biopolymer is given in Figure 1(a). The presence of calcium (Ca), chlorine (Cl), and phosphate (P) elements was detected in the general XPS spectrum. It is predicted that the Ca element seen here may originate from calcium carbonate residues found in the shells of the chitin raw material used. The P element is thought to originate from phospholipids, phosphate groups and ATP residues. In addition, the Cl element seen in the general spectrum is thought to originate from sodium chloride in seawater or salts used during the process. When we look at the bond structures that the carbon atoms in the structure of the biopolymer can form, the main peak in the C 1s spectrum appears to consist of three peaks at 284.34 eV, 286.07 eV, and 287.56 eV, corresponding to C-C/C-H, C-N and C=O bond structures, respectively (Figure 1(b)). The bond structures that oxygen atoms can form are seen in the three main peaks in the O 1s spectrum, namely C=O, C-O and O-H/COO- bonds, at 531.6 eV, 531.53 eV and 532.77 eV, respectively (Figure 1(c)). In the N 1s spectrum, peaks corresponding to N-C, pyrrole N and NH-CO- bonds are seen at 398.87 eV, 399.9 eV and 401 eV points.

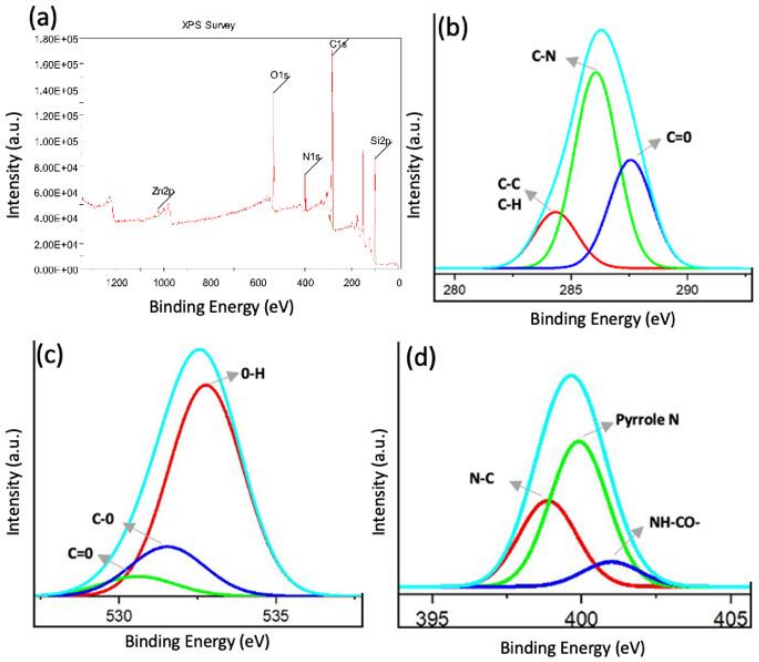

Figure 1. The XPS spectrum of chitin

High-resolution XPS spectra of the chitosan are given in Figure 2. When the general XPS spectrum of the biopolymer is examined, the general XPS spectrum is seen in Figure 2(a). The bond structures that the carbon atoms in the chitosan biopolymer can make consist of three peaks corresponding to the C-C/C-H, C-O/C-O-C and O-C=O bond structures, which occur at 284.9 eV, 286 eV and 288.3 eV, respectively, in the C 1s spectrum, which shows the basic carbon skeleton (Figure 2(b)). The bond structures that the oxygen atoms can make, the C=O, C-O and O-H/COO- bonds, which are seen in the three main peaks in the O 1s spectrum, are seen at 531 eV, 532 eV and 533 eV, respectively (Figure 2(c)). When the N 1s spectrum is examined, it is seen that the peaks at 398.8 eV, 399.8 eV and 401.3 eV correspond to N-C, pyrrole N and NH-C bond structures (Figure 2(d)). The XPS results mentioned here are taken from our previous study (Genc et al. 2025)

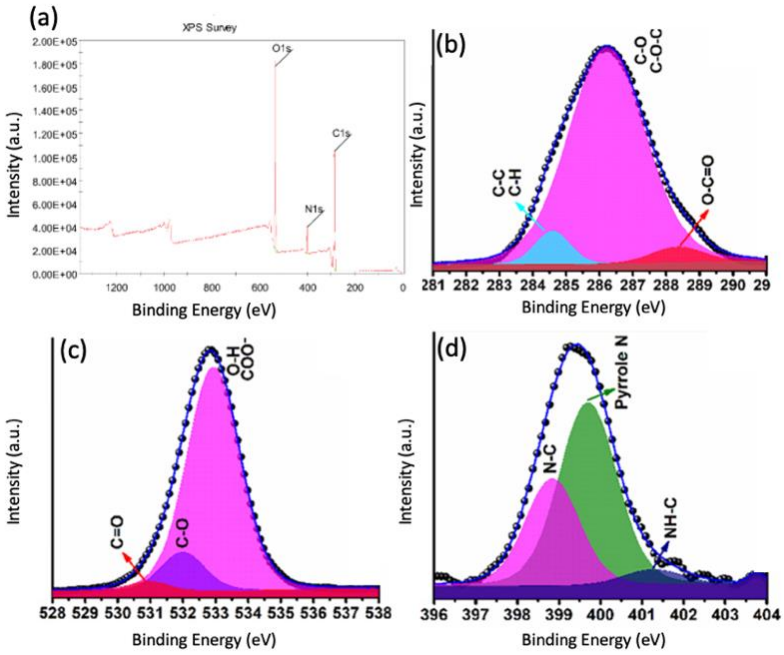

Figure 2. The XPS spectrum of chitosan

SEM analysis was performed to study the surface morphology of chitin and chitosan biopolymers, which increased reaction stability as support materials. According to SEM images, the leafy and partially rough structure of chitin and chitosan biopolymers creates an adhesion surface during the photocatalytic reaction with MoS_2 catalyst. The increased photocatalytic activity and the retention of chitin fragments by the immobilized biopolymers are attributed to both increased active site formation and facilitating electron transfer. The approximate particle size of the chitosan biopolymers was calculated to be approximately 120 µm.

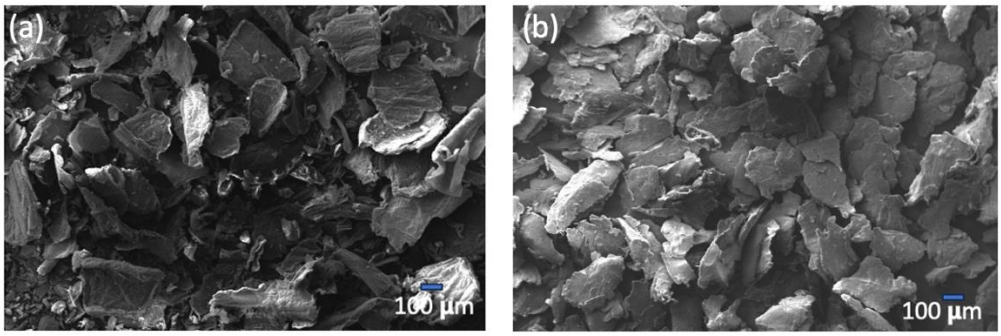

Figure 3. The SEM images of chitin (a) and chitosan (b)

A typical FT-IR spectrum of chitin biopolymer reflects the molecular structures and the characteristic functional groups of the N-acetylglucosamine (GlcNAc) units that constitute this biopolymer. For example, the characteristic peaks belonging to the polysaccharide skeleton observed in the range of ~1000-1200 cm^{-1} originate from C-O-C and C-OH stretching vibrations and confirm the presence of glycosidic bonds in the chitin structure (Gieroba et al. 2023). In addition, the peaks observed around ~1300-1400 cm^{-1} represent the C-N and N-H vibrations in the amide III groups of chitins and support the structural properties of chitin. The peak observed around ~1550 cm^{-1} represents the N-H vibrations in the amide II groups of chitins. The peak observed in the range of ~1620-1650 cm^{-1} represents the carbonyl (C=O) vibrations in the N-acetyl groups (Amide I). The broad peaks occurring between 3200 and 3500 cm^{-1} reflect N-H stretching vibrations originating from the hydroxyl (O-H) groups and amide groups in chitin. The peak width in this range is associated with the presence of hydrogen bonds between chitin molecules. It is also predicted that this may be related to moisture adsorption by chitin. Peaks other than those listed above are due to protein and mineral residues present in the chitin structure. In another FT-IR analysis results, ~ 3100-3500 cm^{-1} absorption band represents hydroxyl (O-H) and amine (N-H) groups of chitosan. Characteristic backbone of chitosan, C-H bonds absorption peaks present ~2800-2900 cm^{-1}. Amide II band shows strong peaks ~1650 cm^{-1} related with C=O bond vibrations. Moreover, amide II bands of chitin peaks shown, ~1580 cm^{-1} related with C-N bond absorptions. Amide III band peaks seen around 1220-1320 cm^{-1} related with N-H bending and C-N stretching vibrations. The C-N bonds in the glucosamine unit peaks have absorption peaks around 1000-1200 cm^{-1}. Peaks in the 1000-1150 cm^{-1} range are related to the C-O-C bridge and C-O stretching of the hydroxyl groups in the chitosan backbone (Amaral, Granja, and Barbosa 2005). Spectrum results confirm the typical band structures of chitin and chitosan. Since chitosan is obtained by deacetylation of chitin, a decrease in amide groups and a pronounced C-O band were observed. Typical weak Mo-S bands were observed in the MoS_2 spectrum around 470-520 cm^{-1}. Changes indicating physical interaction are observed in the chitin-MoS_2 composite spectrum. The shift and broadening of the N-H and O-H bands observed around 3200-3500 cm^{-1} can be attributed to the interaction of the functional groups in chitin with MoS_2. The displacements in the amide bands observed around 1650-1550 cm^{-1} can be attributed to the rearrangement of hydrogen bonds. The intensity increases and shift in the 1000-1100 cm^{-1} region may be due to the attachment of chitin to the MoS_2 surface. Furthermore, the appearance of the Mo-S band around 500 cm^{-1} is the strongest evidence for the presence of MoS_2 in the composite. The spectral results of the chitosan-MoS_2 composite indicate that hydroxyl and amino groups are bonded to the MoS_2 surface. In other words, the chitosan-MoS_2 composite structure was successfully obtained. The interaction of the -OH and -NH_2 groups of chitosan with MoS_2 is evident from the band shift around 1600-1500 cm^{-1}. The shift around 1000-1100 cm^{-1} is attributed to the surface interaction of the amine groups. The most significant change indicating the interaction is the appearance of the Mo-S band around 500 cm^{-1}. All these results confirm the composite formation (Figure 4).

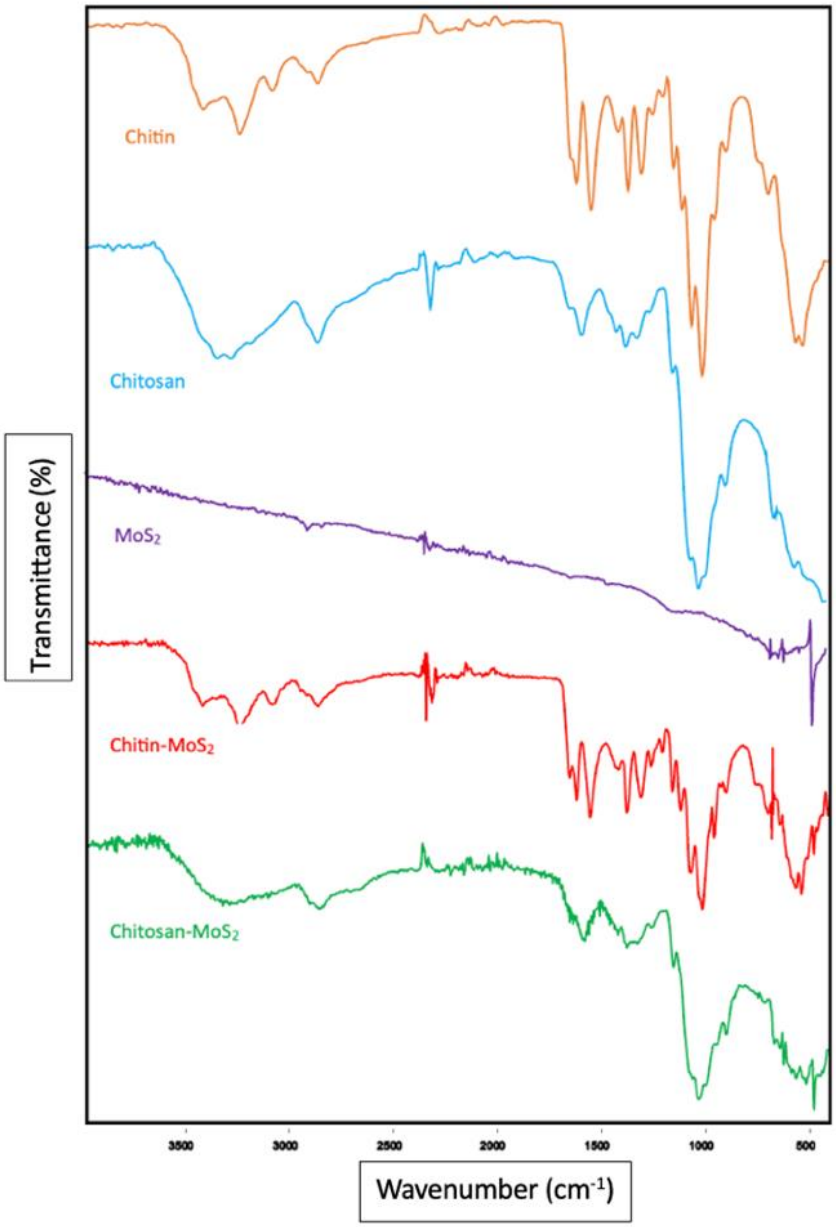

Figure 4. The FT-IR results of chitin, chitosan, MoS_2, chitin-MoS_2, chitosan-MoS_2 catalysts.

The optimum amounts of chitin and chitosan biopolymers that yielded the highest hydrogen production in photocatalytic hydrogen production studies were optimized by adding different amounts of biopolymer to the reaction medium. The optimum amounts were determined as 7 mg for chitin and 1 mg for chitosan, and all hydrogen production studies were conducted using these values (Figure 5(a), (b)). According to photocatalytic hydrogen production studies, chitin, chitosan biotemplates and MoS_2 catalyst did not produce any hydrogen without a light absorber. This indicates that the chitin, chitosan biopolymers and MoS_2 catalyst cannot absorb the light in the photocatalytic hydrogen production reaction. Hydrogen production in the presence of EY dye in the reaction medium of the MoS_2 catalyst in its pure form was measured as 771.57 μmol $h^{-1}g^{-1}$ and 1422.28 μmol g^{-1} at 1 hour and 8 hours, respectively. Hydrogen production in the presence of EY dye in the reaction medium of chitin was measured as 472 μmol $h^{-1}g^{-1}$ and 2389,37 μmol g^{-1} at 1 hour and 8 hours, respectively. Hydrogen production of the chitosan biopolymer in its pure form in the presence of EY was measured as 296,43 μmol $h^{-1}g^{-1}$ and 1505,11 μmol g^{-1} at 1 hour and 8 hours, respectively. Hydrogen production in the presence of chitin biotemplate in the reaction medium of MoS_2 catalyst was measured as 621.53 μmol $h^{-1}g^{-1}$ and 2667,42 μmol g^{-1} at 1 hour and 8 hours, respectively. This was measured as 809,08 μmol $h^{-1}g^{-1}$ and 1879,7 μmol g^{-1} for the 1st and

8th hours, respectively, when chitosan was added to the reaction medium (Figure 5(c), (d)). The hydrogen production efficiency of the MoS_2 semiconductor catalyst increased with the presence of chitin and chitosan biopolymers in the aqueous medium, and this also affected the reaction stability. Moreover, Figure 5(e), (f) shows UV-Vis absorption spectroscopy results. According to these results, the characteristic absorption peak was measured at 520 nm before the reaction for reactions involving both chitin and chitosan biopolymers, and this peak shifted to 490 nm after the reaction (blue shift). The reactions using chitin-MoS_2 and chitosan-MoS_2 catalysts had the highest absorption peaks, indicating higher photostability and less Br removal from the EY dye.

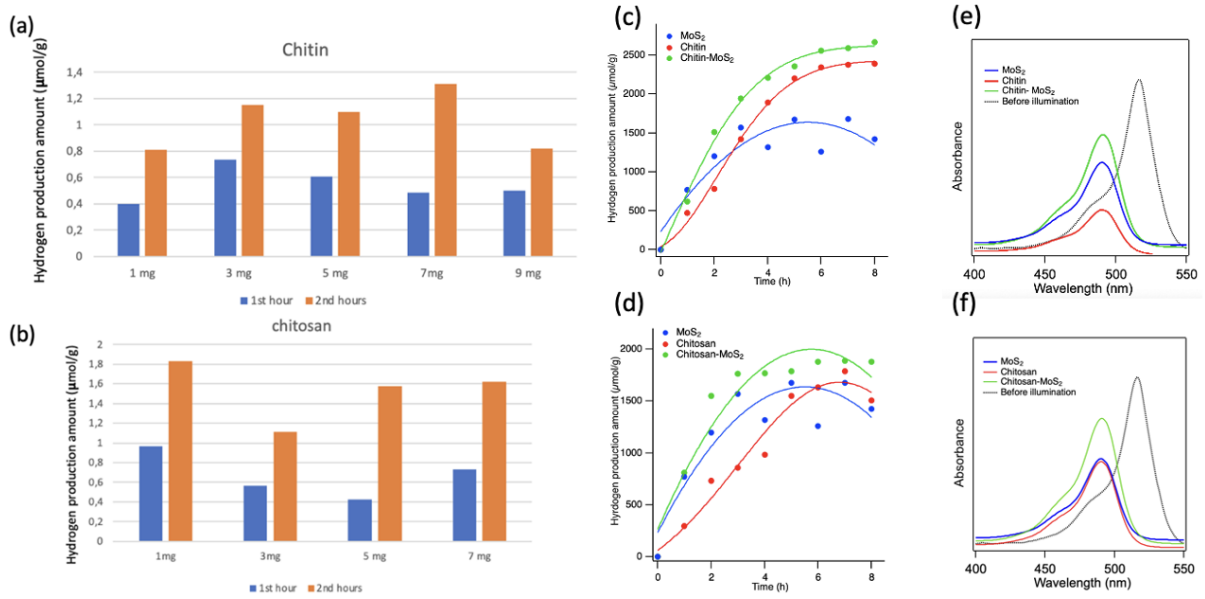

Figure 5. The hydrogen evolution reaction and UV-Vis spectrum results of chitin, chitosan, MoS_2, chitin-MoS_2, chitosan-MoS_2 catalysts.

The proposed mechanism of the biopolymer-MoS_2 composite catalyst is given in Figure 6. According to this mechanism, visible light is first absorbed by the EY dye. EY dye absorbs the photons, under visible light illumination. After that, photogenerated electrons are transferred from the HOMO level of the EY dye to the LUMO level (-1.1 V). The excited electrons are then transferred from the LUMO of the sensitizers to the MoS_2 catalyst. The excited electrons accumulate in the conduction band of the MoS_2 and are transferred to the active sites. Proton reduction occurs in the active sites, producing molecular hydrogen. Here, the reduced protons are absorbed by the S atoms of the MoS_2 catalyst. At the same time, TEOA can regenerate the excited form of the EY by donating electrons. Since electrons cannot be excited in the dark, hydrogen production does not occur. Photocatalytic hydrogen production activity increases in the presence of biopolymers (chitin or chitosan) in the reaction medium. Biopolymers, thanks to their functional groups, create a surface area for binding to the MoS_2 catalyst, preventing catalyst aggregation and increasing the number of active sites. Biopolymers can also act as mediators, facilitating electron transfer and thus preventing recombination.

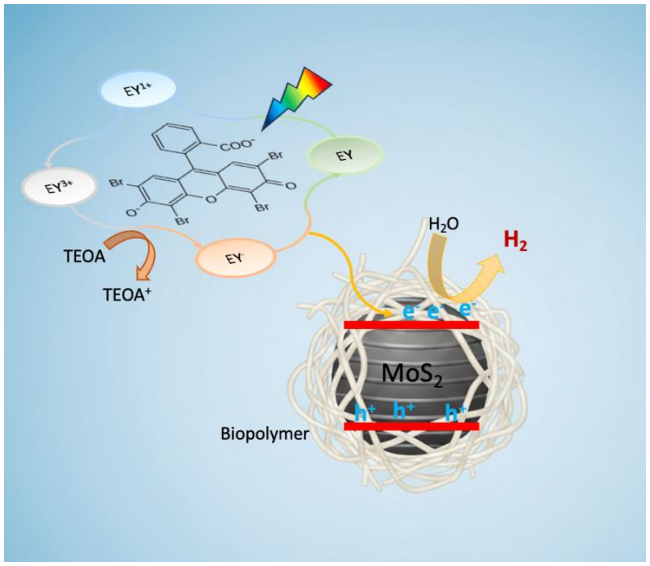

Figure 6. Suggested photocatalytic hydrogen evolution mechanism of biyopolimer-MoS_2 catalyst

CONCLUSION

In conclusion, photocatalytic hydrogen production using the MoS_2 catalyst was successfully achieved in the presence of chitin and chitosan biopolymers in the reaction medium. The obtained data indicate that the biopolymers act as biotemplates by providing a binding surface for the catalyst and increasing the number of active sites. Furthermore, by acting as mediators in the reaction medium, they contribute to increased hydrogen production by facilitating electron transfer and preventing recombination. Therefore, this study offers an alternative route for hydrogen production and storage studies. Consequently, this study will also enable the design and production of nanocomposites for green energy production and storage using bio-based heterostructure catalysts.

ACKNOWLEDGEMENTS

The authors would like to thank to Prof. Dr. Imren HATAY PATIR for providing the lab facilities.

Abstract

Pseudomonas aeruginosa is an opportunistic pathogen that causes serious infections, particularly in immunocompromised individuals. Its exceptional adaptability, low outer membrane permeability, multiple efflux pumps, antibiotic-modifying enzymes, and robust biofilm-forming capacity make it extremely difficult to eradicate. In this context, the current study investigated the potential roles of BON domain-containing proteins (BDCPs) in *P. aeruginosa* biofilm resistance. BON domains, typically ~60 amino acids in length, are known to be membrane-associated, binding to phospholipid bilayers and contributing to the maintenance of outer membrane integrity. In this study, both planktonic and colonial biofilm cultures were established using the reference strain *P. aeruginosa* PAO1 and the clinical isolate PA47. Comparative gene expression analysis revealed that *PA4426* and *PA4739*, encoding BDCPs, were significantly upregulated in biofilm cells of both strains. These findings suggest that elucidating the functional roles of BDCPs in *P. aeruginosa* may aid in the identification of new antibacterial targets and the development of new strategies to overcome antibiotic and biofilm resistance.

Keywords: *Pseudomonas aeruginosa*, BON domain–containing proteins, antibiotic and biofilm resistance, *PA4426, PA4739* gene expression, planktonic and biofilm forms

Introduction

Pseudomonas aeruginosa is an opportunistic pathogen that causes severe infections, particularly in immunocompromised individuals. Its high adaptability, diverse resistance mechanisms, and strong ability to develop multidrug resistance make it one of the most challenging microorganisms to treat in modern clinical practice. Several studies have reported that *P. aeruginosa* is a leading cause of morbidity and mortality in immunocompromised patients, and that increasing antibiotic resistance further enhances its clinical significance (Evans et al., 2023; Qin et al., 2022). Natural resistance mechanisms such as low outer-membrane permeability, multiple efflux pumps, antibiotic-modifying enzymes, and biofilm formation, combined with mutations and horizontal gene transfer, significantly reduce the likelihood of successful treatment. According to the World Health Organization (WHO, 2024), *P. aeruginosa* is classified among “high-priority pathogens,” emphasizing the urgent need for the development of novel therapeutic strategies (Sati et al., 2025). The pathogenicity of *P. aeruginosa* is multifactorial and involves a wide range of virulence factors, including exotoxins, exoenzymes, toxic effector proteins, secondary metabolites such as pyocyanin, siderophores, motility mechanisms, and biofilm formation (Krell & Matilla, 2024). These virulence determinants enable the bacterium to evade host immune defenses and establish chronic infections. The increasing incidence of *P. aeruginosa*–associated multidrug-resistant infections in intensive care units across Türkiye further highlights its national and global clinical relevance.

Biofilms are complex, surface-associated bacterial communities embedded within a self-produced extracellular polymeric substance (EPS) matrix, serving as a survival strategy under fluctuating environmental conditions such

as temperature or nutrient availability (Hall-Stoodley et al., 2004). Bacteria within biofilms can exhibit up to 1,000-fold greater resistance to antimicrobial agents compared with their planktonic counterparts and can effectively evade the host immune response (Høiby et al., 2011). By protecting cells from phagocytosis and environmental stress, biofilms promote long-term persistence and are frequently detected in chronic lung, wound, and sinus infections. Studies have shown that biofilms are present in approximately 78% of chronic wound infections and impose an annual economic burden exceeding USD 25 billion on the U.S. healthcare system (Malone et al., 2017; Mendoza et al., 2019; Sen et al., 2009). Early detection of infections prior to biofilm maturation is therefore critical for therapeutic success (Malone et al., 2017). *P. aeruginosa* is known as a strong biofilm former, making it an ideal model organism for studying biofilm-related resistance mechanisms (Costerton et al., 1999; Tolker-Nielsen, 2014).

The BON (bacterial OsmY and nodulation) domain is approximately 60 amino acids long and adopts an α/β-fold containing a conserved glycine residue and hydrophobic regions, suggesting a role in phospholipid binding rather than catalysis (Yeats & Bateman, 2003). BON domain–containing proteins (BDCPs) are thought to play critical roles in maintaining outer-membrane integrity, sensing environmental stress, and regulating antibiotic resistance in Gram-negative bacteria (Sun & Chen, 2025). However, compared with well-characterized outer-membrane proteins, BDCPs remain poorly understood. Recent studies have revealed their contribution to antibiotic resistance. For instance, BonA in *Acinetobacter baumannii* is associated with polymyxin resistance (Grinter et al., 2021), while the loss of DolP in *Escherichia coli* increases antibiotic susceptibility (Bryant et al., 2020). LysM-BON family proteins have also been reported to interact with carbapenems, thereby promoting resistance (Ali et al., 2020). Moreover, a newly identified BDCP displaying efflux pump activity conferred resistance to a broad spectrum of antibiotics, particularly ceftazidime (Sun et al., 2023).

Proteomic analyses have revealed differential expression of BON domain proteins between environmental and clinical isolates of *Pseudomonas sp.*, suggesting potential roles in stress adaptation and membrane homeostasis (Liew et al., 2021). BON domain genes appear to be under positive selection pressure in environmental strains, indicating evolutionary adaptation to stress conditions (Liew et al., 2021). Structural analyses suggest that BON domains interact with phospholipids to preserve membrane stability under stress (Yeats & Bateman, 2003; Bryant et al., 2020). In *P. aeruginosa* PAO1, the ***PA4426*** gene encodes a 233-amino-acid protein with an approximate molecular weight of 25.9 kDa (UniProtKB: Q9HVY9). The ***PA4739*** gene (UniProtKB: Q9HV60) also encodes a BON domain–containing protein predicted to localize to the periplasm or outer membrane. The protein possesses an N-terminal signal peptide of approximately 25 amino acids and a single BON domain of ~114 amino acids, modeled by the AlphaFold Protein Structure Database. As far as we know, there are no information about BDCPs role in biofilm of *P. aeruginosa*.

Materials and Methods

Culture Condition of Bacterial Strains and Colony Biofilm Assay

In this study, the reference strain *P. aeruginosa* PAO1 and strong biofilm-forming clinical isolate PA47 were used. Briefly, bacterial cultures were grown in 5 mL medium and incubated for 24 h. The optical density (OD_{600}) was adjusted to 0.08–0.1. For colony biofilm formation, 0.22 µm polycarbonate membranes were sterilized under UV for 10 min, placed on agar plates, and further sterilized. The 5 µL aliquot from a bacterial suspension adjusted to 0.5 McFarland standard was inoculated onto the membrane surface and incubated statically at 37 °C for 24 h. Membranes were then transferred to fresh agar plates and incubated for an additional 24 h. After 48 h, membranes were placed in 1 mL PBS and vortexed to detach biofilm cells (Merritt et al., 2011). The harvested cells were used for RNA extraction.

RNA Isolation, cDNA Synthesis, and Quantitative PCR (qPCR) Analysis

Total RNA was extracted from both planktonic and biofilm cells using the TRIzol® Reagent protocol. After 48 h of incubation, the cells were pelleted by centrifugation, resuspended in 1 mL TRIzol, and homogenized. RNA was extracted with phenol:chloroform (25:24:1), precipitated with isopropanol, washed with 75% cold ethanol, air-

dried, and stored at −80 °C. RNA concentrations were quantified spectrophotometrically, and 1 µg of total RNA from each sample was reverse transcribed into cDNA using a commercial reverse transcription kit. The reaction was performed at 25 °C for 10 min, 37 °C for 120 min, and 85 °C for 5 min. cDNA samples were stored at −20 °C until use. Quantitative PCR (qPCR) reactions (final volume 10 µL) contained 4 µL RT-PCR master mix, 0.5 µL of each primer, 2 µL cDNA, and 3 µL nuclease-free water. The amplification program consisted of an initial denaturation at 95 °C for 2 min, followed by 40 cycles of 95 °C for 30 s, 61 °C for 20 s, and 72 °C for 10 s. Cycle threshold (Ct) values were normalized using the housekeeping gene *rpoD*, and relative expression changes were calculated using the $2^{-(\Delta\Delta Ct)}$ method.

Results and Discussion

The BON (Bacterial OsmY and Nodulation) domains are known to interact with phospholipid membranes, contributing to the maintenance of outer membrane integrity and enhancing resistance to stress conditions in Gram-negative bacteria (Yeats & Bateman, 2003; Bryant et al., 2020). Previous studies have demonstrated that BON domain proteins such as DolP in *Escherichia coli* and BonA in *Acinetobacter baumannii* are involved in outer membrane homeostasis and resistance to membrane-targeting antibiotics (Grinter et al., 2021; Ranava et al., 2021). This study investigated the expression profiles of two BON domain–containing genes, *PA4426* and *PA4739,* in *P. aeruginosa* under planktonic and colony biofilm growth conditions. Quantitative gene expression analyses showed that, in both the reference strain PAO1 and the clinical isolate PA47, the expression levels of these genes were significantly higher in biofilm cultures compared to planktonic cells. As shown in Figure 1, *P. aeruginosa* formed a colony biofilm structure under static conditions, confirming the successful establishment of biofilm cultures. These findings indicate that the observed gene expression differences are associated with biofilm-specific physiological states.

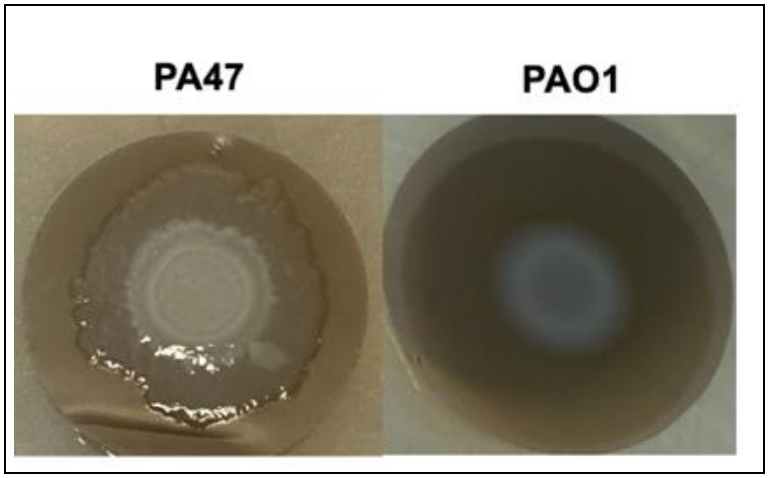

Figure 1. Colony biofilm structure of *Pseudomonas aeruginosa***.**

In Figure 2A–D, both ***PA4426*** and ***PA4739*** exhibit significant and strain-dependent transcriptional induction under biofilm conditions in *P. aeruginosa*. In the reference strain **PAO1, *PA4739*** shows a **6–7-fold increase ($p<0.0001$)**, whereas the clinical isolate **PA47** displays an even more dramatic **~40-fold upregulation ($p<0.001$),** indicating that *PA4739* is strongly biofilm responsive in both genetic backgrounds, with particularly pronounced induction in PA47. Similarly, ***PA4426*** is clearly induced in biofilms; in **PAO1**, expression rises by approximately **145-fold ($p<0.0002$)**, representing the most substantial transcriptional activation among the tested genes, while in **PA47** the increase is more modest, approximately **1-fold but still statistically significant ($p<0.05$).** Together, these data demonstrate that both BON-domain–containing genes are consistently activated in a biofilm-dependent manner, albeit with markedly different magnitudes between strains. The collective upregulation profiles in Figure 2 suggest that ***PA4426*** and ***PA4739*** contribute to conserved, biofilm-associated

physiological processes, potentially involving membrane stabilization, periplasmic stress adaptation, or early steps of antibiotic tolerance. Although their exact biochemical functions remain unresolved, their predicted localization to the outer membrane or periplasm, combined with the presence of BON domains, supports a **structural or regulatory** role rather than enzymatic activity. Further studies such as targeted knockouts, lipid-binding assays, and proteomic analyses will be essential to clarify their mechanistic contributions to biofilm maturation and associated survival pathways in *P. aeruginosa*.

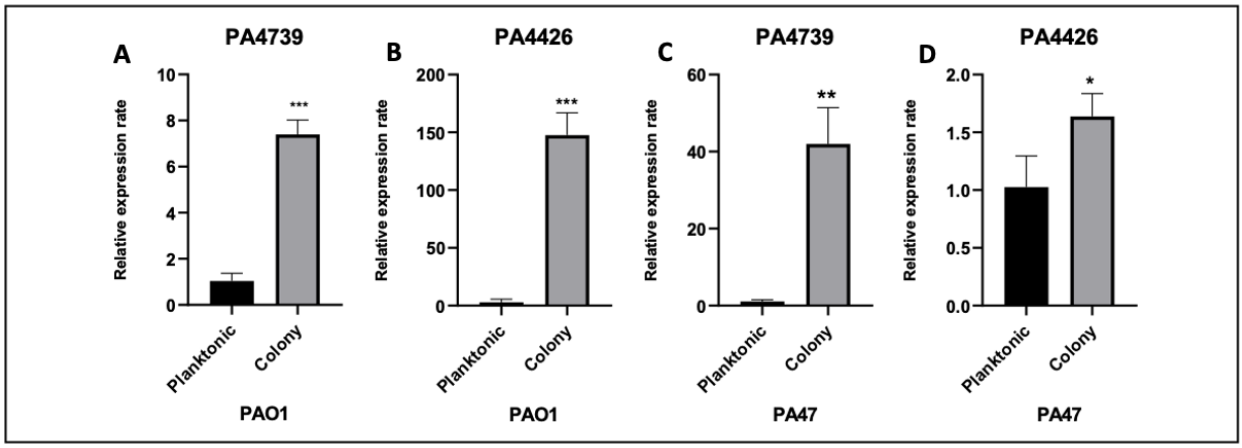

Figure 2. Comparison of *PA4426* and *PA4739* gene expression levels in planktonic and biofilm cultures of *Pseudomonas aeruginosa*.

Conclusion

In conclusion, the *PA4426* and *PA4739* genes were found to be expressed at higher levels in colony biofilm cultures compared to planktonic cells. This observation suggests that these genes may play important roles in biofilm-specific adaptive processes, such as antibiotic tolerance, biofilm stability, and structural maintenance. Given that biofilms provide a protective niche enabling *P. aeruginosa* to survive under antibiotic and environmental stress, the upregulation of BON domain–containing genes in this condition may reflect a broader bacterial strategy to reinforce membrane robustness and sustain long-term persistence. These findings highlight *PA4426* and *PA4739* as biofilm-associated resistance. Elucidating their precise mechanisms through targeted mutagenesis, protein localization studies, and lipid-binding assays will be essential for understanding how BON domain–containing proteins contribute to the complex defense network of *P. aeruginosa*. Ultimately, such insights could guide the development of novel therapeutic strategies aimed at disrupting biofilm integrity and overcoming antibiotic resistance in multidrug-resistant *P. aeruginosa* strains.

Özet

İnsan ölümlerinde kronik bulaşıcı olmayan hastalıklar önemli bir yer tutmaktadır. Dünya Sağlık Örgütü'nün 2018 istatistikleri, toplam 57 milyon ölümün %71'inden (41 milyon kişi) kronik bulaşıcı olmayan hastalıkların sorumlu olduğunu bildiriyor. Kardiyovasküler hastalıkların en önemli risk faktörleri hipertansiyon ve hiperkolesterolemidir. 3-Hidroksi-3-metil-glutaril-CoA redüktaz, hiperkolesterolemiye neden olan kolesterolün sentez yolundaki anahtar bir enzimdir. Kolesterol sentezini engellemenin çözümlerinden biri de HMG-CoA redüktaz enzimini bloke eden ilaçlar kullanmaktır. HMG-CoA redüktazın inhibisyonu ile HMG-CoA'nın mevalonata dönüşümü ve dolayısıyla sonraki ürünlerin sentezi sonlandırılmış olur. Bu sonlanma aynı zamanda çeşitli kanser hücresi türlerinde büyümenin durdurulmasına ve hücre ölümüne de hizmet etmektedir.

Bu çalışmada, birçok hastalığa karşı ilaç olarak kullanılmasının yanı sıra aroma verici, baharat ve gıda koruyucu Thymus Canoviridis yapısında bulunan 21 bileşik moleküler yerleştirme metodu ile HMG-CoA enzim bağlanma bölgesine yerleştirilmiş ve bağlanma bölgesindeki ligand-kalıntı etkileşimleri incelenmiştir. Kullanılan bileşiklerin HMGR enziminin aktifliğinde önemli roller üstlenen Glu559, Cys668, Lys691 ve Lys692 gibi kalıntılar ile çeşitli etkileşimler gerçekleştiği belirlenmiştir. Yapılan yerleştirme sonucunda rutin bileşiğinin −8.96 kcal/mol'lük bağlanma serbest enerji değeri ile en iyi sonucu verdiği belirlenmiştir. Ayrıca rutin bileşiğinin yanı sıra hesperidin ve nikotiflorin bileşiklerinin de bir HMGR inhibitörü olan RSV'den daha iyi sonuç verdiği belirlenmiştir.

Anahtar Kelimeler: HMGR, Moleküler Yerleştirme (Docking), *Thymus Canoviridis*

Investigation of the effects of some *thymus canoviridis* plant's extracts on HMGR enzyme inhibition using molecular docking method

Abstract

Chronic noncommunicable diseases (NCDs) play a significant role in human mortality. The World Health Organization's 2018 statistics report that chronic NDCs account for 71% of the 57 million deaths (41 million people). The most important risk factors for cardiovascular disease are hypertension and hypercholesterolemia. 3-Hydroxy-3-methyl-glutaryl-CoA reductase is a key enzyme in the cholesterol synthesis pathway that causes hypercholesterolemia. One solution to inhibit cholesterol synthesis is the use of drugs that block the HMG-CoA reductase enzyme. Inhibiting HMG-CoA reductase halts the conversion of HMG-CoA to mevalonate and, consequently, the synthesis of downstream products. This inhibition also serves to inhibit growth and cell death in various types of cancer cells. In this study, 21 compounds found in Thymus Canoviridis, which are used as a flavoring agent, spice, and food protectant in addition to being used as drugs against many diseases, were docked to the HMG-CoA enzyme binding site using the molecular docking method, and ligand-residue interactions in the binding site were investigated. Various interactions were observed with residues such as Glu559, Cys668, Lys691, and Lys692, which play important roles in the activity of the HMGR enzyme. The docking results indicated that rutin yielded the best binding free energy value of −8.96 kcal/mol. Furthermore, in addition to rutin, hesperidin and nicotiflorin also gave better results than RSV, an HMGR inhibitor.

Keywords: HMGR, Molecular Docking, *Thymus Canoviridis*

GİRİŞ

Kardiyovasküler hastalık (KVH), kanser, kronik solunum yolu hastalığı ve diyabet, ölüme neden olan dört ana bulaşıcı olmayan hastalıktır (BOH). Hipertansiyon ve hiperkolesterolemi, KVH hastalıklarının önemli risk faktörleridir (Bays ve ark., 2021). Mevalonat yolunda asetil-CoA'dan türeyen kolesterol hiperkolesterolemiye neden olmaktadır (Mullen ve ark., 2016). Kolesterol sentezi, önemli bir enzim olan 3-Hidroksi-3-metilglutaril-CoA (HMG-CoA) redüktazın (HMGR) inhibisyonuyla önlenebilir. HMGR'nin inhibisyonu, HMG-CoA'nın mevalonata dönüşümünün ve sonraki ürünlerin sentezinin sona ermesiyle sonuçlanır. Çalışmalar, bu yolun sonlandırılmasının çeşitli kanser türlerindeki hücrelerde büyümenin durmasına ve hücre ölümüne neden olabileceğini ortaya koymuştur (Bennis ve ark., 1993; Caruso ve ark., 1999; Hawk ve ark., 1996; Istvan ve ark., 2000; Lee ve ark., 1998). Statinler, mantar metabolitlerinden veya mikrobiyal kaynaklardan elde edilen ve HMGR'yi inhibe etmek için kullanılan en popüler inhibitörlerdir (Moorthy ve ark., 2015). HMGR'nin inhibisyonunda ve düşük yoğunluklu lipoprotein düzeylerinin düşürülmesinde büyük başarı gösterilmesine rağmen, araştırmalar LDL-C'yi ABD Kolesterol Eğitim Programı tarafından tercih edilen düzeylere (70 mg/dL) düşürmek için gereken yüksek dozdaki statinlerin miyaljiye neden olabileceğini göstermiştir (Grundy ve ark., 2004).

888 kalıntıdan oluşan HMGR, üç alanda araştırılabilir: membran çapa bölgesi (1-339 kalıntı), bağlayıcı bölge (340-459 kalıntı) ve katalitik bölge (460-888 kalıntı). HMGR'nin katalitik bölgesi yapısal olarak üç alt alana ayrılmıştır: N-terminal bölgesi, büyük bir alan L-bölgesi ve küçük bir alan S-bölgesi. En küçük alan olan N terminal bölgesi, 460-527 kalıntılarını içerir ve HMGR'nin katalitik kısmını membran bölgesine bağlar (Istvanve ark., 2000). Merkezi L-bölgesi (528-590), bir ENVIG dimerizasyon motifine sahiptir (Son ve ark., 2013). Katalitik bölgenin S-bölgesi (592-682), DAMGMN NAD(P) bağlanma motifini içerir (Sonve ark., 2013) ve L-bölgesinin Lβ3 ve Lα2 bölümlerinin arasına yerleştirilmiştir (Istvanve ark., 2000). S-alanı, HMG bağlanma bölgesi için gerekli olan β-zincir (Lβ3 ve Sβ1) ve cis-döngü (kalıntılar 682-694) aracılığıyla L-bölgesine bağlanır (Istvanve ark., 2000).

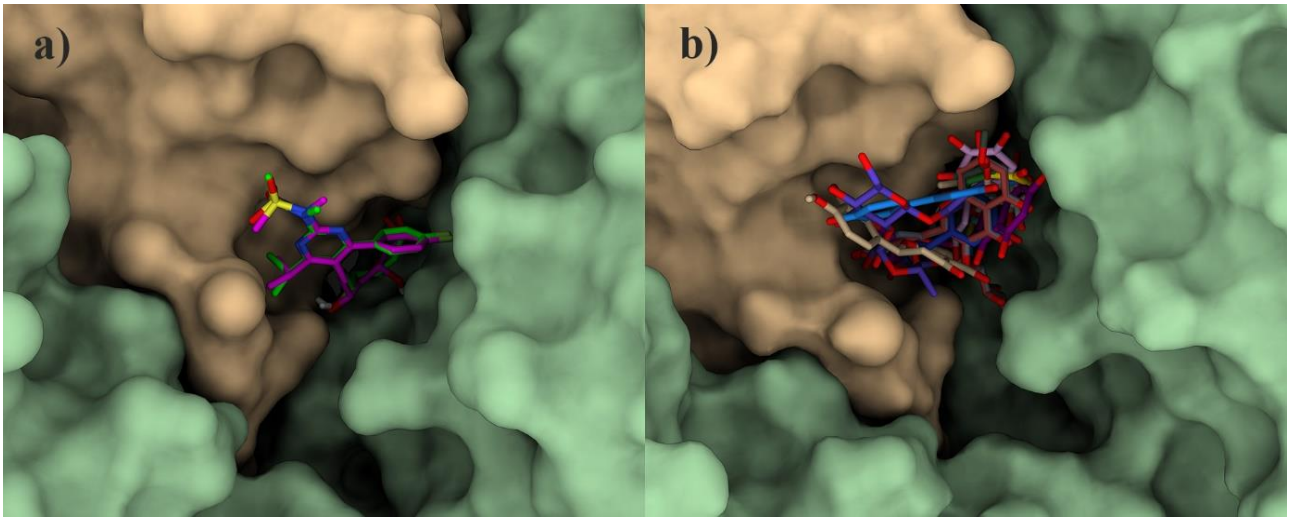
Bugüne kadar, statin türevleri (Pfefferkorn ve ark., 2007; Sonve ark., 2013), statin olmayanlar (Bose ve ark., 2023; Silva ve ark., 2021) ve doğal kaynaklara (Aulifa ve ark., 2024; Marahatha ve ark., 2021) dayalı bileşikleri inhibitör adayları olarak kullanarak HMGR'yi inhibe etmek için *in vitro* ve/veya *in silico* yöntemlerini içeren birçok çalışma gerçekleştirilmiştir.

Thymus türlerinin çoğu birçok hastalığa karşı ilaç olarak ve aynı zamanda aroma verici ve gıda koruyucu amaçla kullanılmaktadır. *Thymus* türleri antiseptik, öksürük kesici, balgam söktürücü, antispazmodik ve antienflamatuvar gibi birçok biyolojik ve farmakolojik özelliklere sahiptirler. Birçok *Thymus* türünün yaprak ve çiçekleri, ishal, ateş, öksürük, yara ve sayısız enfeksiyonların tedavisinde toz, dekoksiyon veya infüzyon şeklinde kullanılırlar (Jamali ve ark., 2012). Ayrıca *Thymus* türleri antispazmodik, yatıştırıcı, antioksidan, antimikrobiyal, antifungal, antibakteriyel ve antiaflatoksijenik özellikleriyle de bilinirler (Jabri-Karoui ve ark., 2012).

Bu çalışmada *Thymus Canoviridis* yapısında bulunan 21 bileşik moleküler yerleştirme metodu ile HMGR enzim bağlanma bölgesine yerleştirilmiş ve bağlanma bölgesindeki ligand-kalıntı etkileşimleri incelenmiştir.

Bilgisayar destekli ilaç tasarım teknikleri, ilaç tasarım ve geliştirme süreçlerinde yaygın olarak kullanılmaktadır (Sanyaolu ve ark., 2021; Talele ve ark., 2010) ve ilaç geliştirme sürecinin maliyetini %50'ye kadar düşürdüğü bildirilmiştir (Wei & McCammon, 2024). Bununla birlikte, moleküler yerleştirme, hedef molekülün 3 boyutlu yapısını gerektiren yapı tabanlı bir ilaç tasarım yöntemi olan CADD süreçlerinde hızlı ve ekonomik yöntemlerden biridir (Sousa ve ark., 2013). Bu yöntem, ilacın bir ilaç hedefine karşı bağlanma afinitesini tahmin eder (Niazi & Mariam, 2023).

Atorvastatin, simvastatin, fluvastatin ve rosuvastatin (RSV) gibi çeşitli ligandlara ek olarak HMG-CoA ile kompleks oluşturan HMG-CoA redüktaz enziminin bazı kristal yapıları bugüne kadar çözülmüştür (Istvan & Deisenhofer, 2001; Istvanve ark., 2000; Steussy ve ark., 2013; Tabernero ve ark., 1999). RSV'nin, statin grubu inhibitörleri arasında en etkili inhibitör olduğu bildirilmiştir (Holdgate ve ark., 2003; Istvan, 2003; McTaggart ve ark., 2001). Bu nedenle, yeni incelenen ligandların yerleştirme sonuçlarını karşılaştırmak için mevcut çalışmada RSV ile kompleks oluşturan bir enzimin kristal yapısını kullandık.



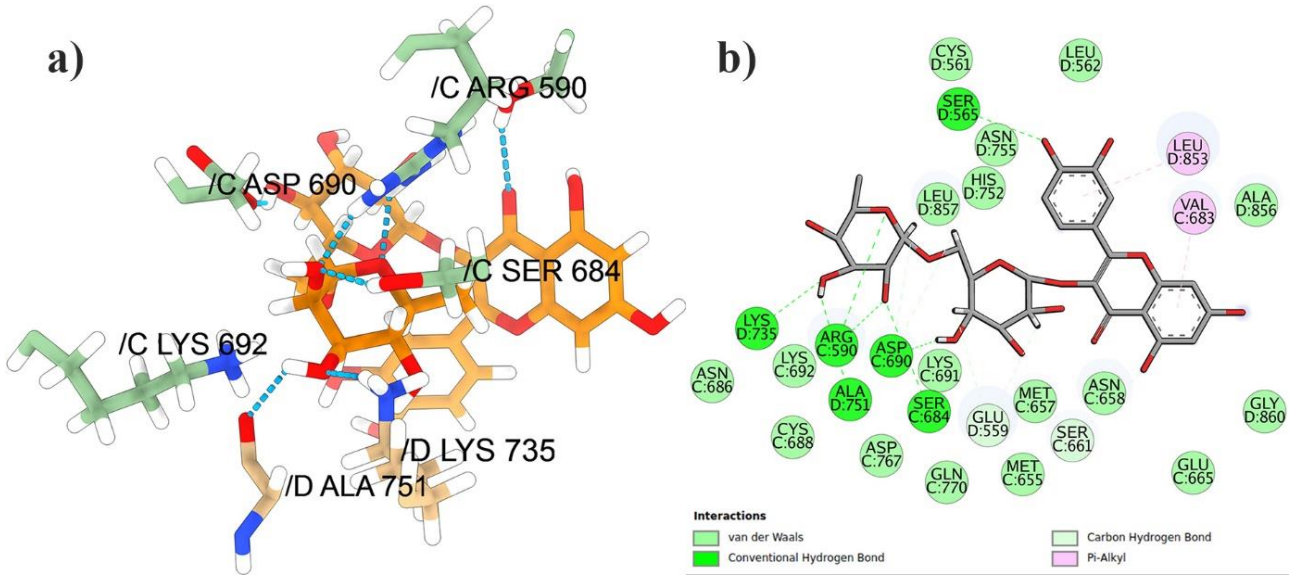
MATERYAL VE METOT

HMGR'nin RSV inhibitörü ile kompleks halindeki kristal yapısı 1HWL (Istvan & Deisenhofer, 2001) koduyla protein veri bankasından (www.rcsb.org) elde edildi. Protein ve RSV yapıları, tüm gereksiz parçacıklar çıkarılarak ayrı ayrı kaydedildi. *Thymus Canoviridis* yapısında bulunan bileşikler PubChem (https://pubchem.ncbi.nlm.nih.gov) sitesinden 3 boyutlu olarak "structure data file" (sdf) formatında indirilerek moleküler yerleştirme için uygun hale getirildi.

Yerleştirme çalışmaları, hızlı ve kullanıcı dostu bir yerleştirme motoru olan Autodock Vina (v1.2.7) (Eberhardt ve ark., 2021) ile gerçekleştirildi. Yerleştirme bölgesi, her bir doğrultuda 16 Å'luk boyutlarında ve sırasıyla x, y ve z doğrultuları üzerinden 21.19, −31.23, 27.05 koordinatlarında bir grid kutusunun kristalize RSV ligandı üzerine ortalanmasıyla tanımlandı. Her molekül için dokuz yerleştirme pozisyonu oluşturuldu. Yerleştirme çalışmaları öncesinde, HMG-CoA'nın enzimin bağlanma bölgesine yeniden yerleştirilmesiyle doğrulama testi gerçekleştirildi.

BULGULAR ve TARTIŞMA

HMGR enzimi ile eş-kristalize şekilde elde edilen RSV ligandının enzime yeniden yerleştirilmesi ile yerleştirme metodunun validasyonu gerçekleştirildi. Yerleştirme sonucu yerleştirilen RSV yapısı ile kristalize RSV yapısı arasında 1.19 Å'luk RMSD değeri olduğu belirlendi (Şekil 1). Bunun yanında enzimin bağlanma bölgesine yerleştirilen bütün bileşiklerin bağlanma modları Şekil 1'de verilmiştir.

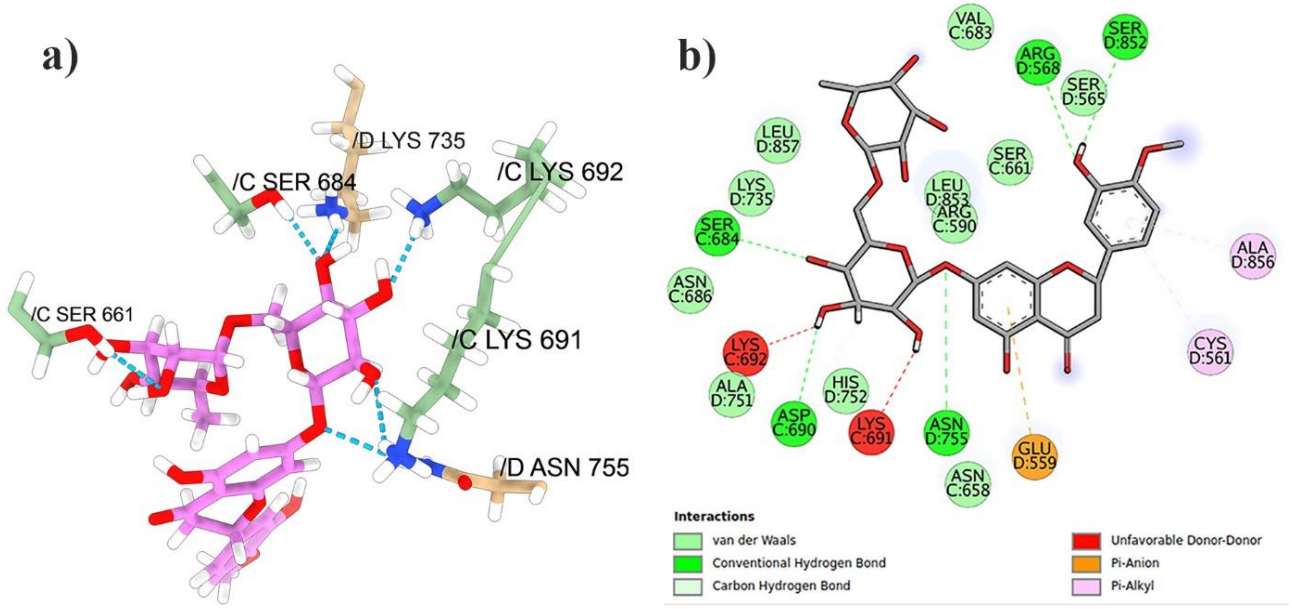


Şekil 1. a) RSV bileşiğinin yeniden yerleştirme sonucu ile kristal yapısının üst üste çakıştırılması (Kristal RSV yapısındaki karbon atomları magenta, yeniden yerleştirilen yapısındaki karbon atomları yeşil ile verilmiştir). b) *Thymus Canoviridis* yapısında bulunan 21 bileşiğin HMGR bağlanma bölgesindeki yerleşim modları (Enzimin C zinciri koyu deniz yeşili, D zinciri ise açık kahverengi ile gösterilmiştir).

Yerleştirme sonuçları Rutin (−8.96 kcal/mol), Hesperidin (−8.74 kcal/mol) ve Nikotiflorin (−8.72 kcal/mol) bileşiklerinin RSV'den (−8.41 kcal/mol) daha iyi skorlar elde ettiğini gösterirken, Fumarik asit (−4.31 kcal/mol) en yüksek bağlanma serbest enerji değerini vermiştir (Tablo 1).

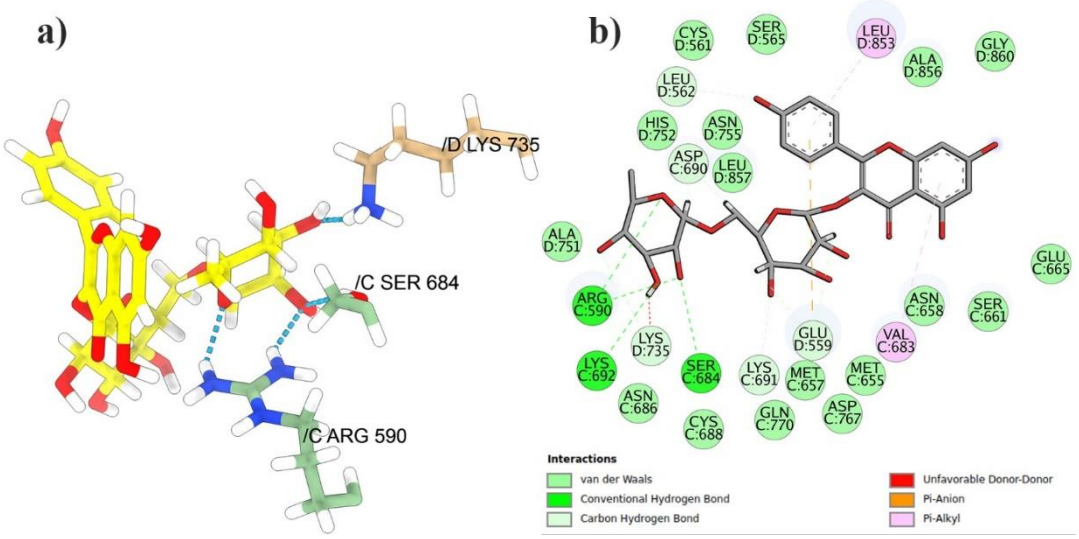
Tablo 1. Çalışmada kullanılan bileşiklerin HMGR bağlanma bölgesindeki yerleşme skorları

Bileşik	Skor (kcal/mol)	Bileşik	Skor (kcal/mol)
Rutin	−8.96	Rosmarinic_acid	−7.57
Hesperidin	−8.74	Hesperetin	−7.55
Nicotiflorin	−8.72	Caffeic acid	−6.36
Rosuvastatin	−8.41	Quinic_acid	−6.27
Rhoifolin	−8.18	Protocatechuic acid	−5.85
Isoquercitrin	−8.10	Salicylic acid	−5.77
Cosmosiin	−8.04	Ferulic acid	−5.72
Chrysin	−7.70	p−Coumaric acid	−5.69
Chlorogenic acid	−7.68	Vanillin	−5.16
Naringenin	−7.68	Malic acid	−5.08
Apigenin	−7.67	Fumaric acid	−4.31



RSV ligandı enzimin kristal yapısında C:Arg590 (iki bağ), C:Asp690, C:Lys691, C:Lys692 ve D:Lys735 kalıntıları ile toplam 6 tane hidrojen bağı oluşturmaktadır (C ve D enzimin homodimer zincirlerini ifade etmektedir.). Bunun yanında yapısındaki flor atomu aracılığıyla C zincirinin Arg590 ve Val683 kalıntıları ile halojen etkileşimleri gerçekleştirirken, C:Arg590 kalıntısı ile pi-katyon, D:Leu583 ve D:Leu857 kalıntıları ile birer tane pi-alkil etkileşimi yapmaktadır. Diğer bileşikler de benzer etkileşimler gerçekleştirmiştir. Buna göre, en iyi bağlanma (−8.96 kcal/mol) gösteren Rutin bileşiği de RSV gibi kalıntı atomları ile 7 adet hidrojen bağ oluşturmaktadır. C:Arg590 (iki bağ), C:Ser684, D:Ser565, D:Lys735, D:Ala751 ve C:Asp690 kalıntıları hidrojen bağ oluşumunda yer almaktadırlar. Bunun yanında Rutin bileşiği C:Val683 ve D:Leu853 kalıntıları ile pi-alkil etkileşimleri gerçekleştirmektedir (Şekil 2).

Şekil 2. Rutin bileşiğinin; **a)** HMGR enziminin bağlanma bölgesinde oluşturduğu hidrojen bağlarının 3 boyutlu gösterimi (Rutin bileşiğinin karbon atomları turuncu, HMGR C ve D zincirlerinin karbon atomları sırasıyla koyu deniz yeşili ve açık kahverengi ile verilmiştir), **b)** tüm etkileşimlerinin 2 boyutlu görünümü.



Çalışılan bileşikler arasında −8.74 kcal/mol'lük bağlanma serbest enerjisi değeriyle Rutin'den sonra en iyi bağlanma gösteren bileşik Hesperidin olmuştur. Hesperidin, C:Ser684, D:Arg568, D:Asn755, D:Ser852 ve C:Asp690 kalıntıları ile hidrojen bağı geliştirirken, D:Glu559 kalıntısı ile pi-anyon ve D:Cys561 ve D:Ala856 kalıntıları ile pi-alkil etkileşimleri oluşturmaktadır. Ayrıca, bileşik C zincirinin Lys691 ve Lys692 kalıntıları ile istenmeyen türden etkileşimler oluşturmaktadır. Bileşiğin yapısındaki alkol hidrojenlerinin lizin amino asidindeki hidrojenler ile etkileşimleri bu istenmeyen etkileşimlere sebep olurken, dinamik ortamda bu hidrojenlerin

bileşikteki alkol oksijenleri ile yakınlaşması durumunda birer hidrojen bağı oluşturma potansiyeli taşıdıkları da göz önüne alınmalıdır (Şekil 3).

Şekil 3. Hesperidin bileşiğinin; **a)** HMGR enziminin bağlanma bölgesinde oluşturduğu hidrojen bağlarının 3 boyutlu gösterimi (Hesperidin bileşiğinin karbon atomları magenta, HMGR C ve D zincirlerinin karbon atomları sırasıyla koyu deniz yeşili ve açık kahverengi ile verilmiştir), **b)** tüm etkileşimlerinin 2 boyutlu görünümü.

RSV'den daha iyi skor elde eden diğer bir bileşik ise nikotiflorin bileşiğidir (−8.72 kcal/mol). Nikotiflorin bileşiğinin etkileşimleri incelendiğinde, bileşiğin Rutin ve Hesperidin'den daha az sayıda hidrojen bağı oluşturduğu gözlenmektedir. Bileşik, ikisi C:Arg590 kalıntısı ve diğerleri C:Ser684 ve C:Lys692 kalıntılarıyla olan 4 adet hidrojen bağı oluşturmaktadır. Buna ek olarak, D:Glu559 kalıntısı ile elektrostatik pi-anyon, C:Val683 ve D:Leu853 kalıntıları ile de hidrofobik pi-alkil etkileşimleri nikotiflorin bileşiğinin oluşturduğu diğer istenen türde etkileşimleri oluştururken, bileşik aynı zamanda D:Lys735 kalıntısı ile istenmeyen türde donör-donör etkileşimi de yapmaktadır (Şekil 4).

Şekil 4. Nikotiflorin bileşiğinin; **a)** HMGR enziminin bağlanma bölgesinde oluşturduğu hidrojen bağlarının 3 boyutlu gösterimi (Nikotiflorin bileşiğinin karbon atomları sarı, HMGR C ve D zincirlerinin karbon atomları sırasıyla koyu deniz yeşili ve açık kahverengi ile verilmiştir), **b)** tüm etkileşimlerinin 2 boyutlu görünümü.

Yerleştirme sonucunda RSV'den daha iyi sonuç veren Rutin, Hesperidin ve Nikotiflorin bileşiklerinin etkileşimleri metinde verilirken, çalışmada yer alan bütün bileşiklerin enzim kalıntıları ile olan etkileşimleri Destekleyici Materyal Tablo D1'de verilmiştir. Bunun yanında, bileşiklerin enzim kalıntılarıyla oluşturdukları etkileşimlerin 2 boyutlu gösterimleri de Destekleyici Materyal Şekil D1-D9'da sunulmuştur.

HMGR'nin katalitik bölgesi, enzimin L ve S bölgeleri arasında yer alır. HMG boyunca uzanan 'cis-döngüsü' bağlanma bölgesinin en önemli yapısal elemanıdır (682-694 kalıntı). Asp690, Lys691 ve Lys692 kalıntılarının konumu, Cys688 ve Thr689'un cis-peptit bağı tarafından sağlanır (Istvanve ark., 2000). Glu559, Lys691 ve His866, katalitik anahtar kalıntılardır (Gesto ve ark., 2020; Miziorko, 2011). Yerleştirme sonuçları, bileşiklerin Cys688 veya Thr689 kalıntılarıyla hidrofobik etkileşim veya hidrojen bağı oluşturmadığını ortaya koyarken, bileşiklerin genel olarak Lys691, Lys692 ve Glu559 kalıntıları ile etkileştikleri gözlenmektedir. Bunun yanında, salisilik asit, fumarik asit, rutin, nikotiflorin, kafeik asit ve protokateşik asidin C:Cys668 kalıntısı ile van der Waals etkileşimleri gerçekleştirmektedir (Şekil 2, 4 ve Destekleyici Materyal Şekil D1-D9). Yerleştirme sonuçları incelendiğinde, *Thymus Canoviridis* bitkisinin yapısında bulunan bileşiklerin HMGR enzimini inhibe etme özelliklerinin olduğu bu çalışma ile belirlenmiştir.

SONUÇ

İnsan vücudundaki kolesterol seviyesini düşürmek için hedef alınan HMGR enziminin bağlanma bölgesine *Thymus Canoviridis* bitkisinin yapısında bulunan bileşikler moleküler yerleştirme yöntemi ile yerleştirilmiştir. Çalışma sonuçları Rutin, Hesperidin ve Nikotiflorin bileşiklerinin, aynı zamanda kolesterol tedavisinde ilaç olarak kullanılmakta olan RSV bileşiğinden daha düşük skorlar elde ettiğini göstermiştir. Bileşiklerin yerleştirilme skorları −8.96 ile −4.31 kcal/mol arasında yer alırken, Rutin −8.96 kcal/mol ile en iyi bağlanma serbest enerjisine sahip olurken, en düşük bağlanma serbest enerjisine sahip bileşik Fumarik asit olmuştur.

Sonuç olarak *Thymus Canoviridis* bitkisinin yapısında bulunan bileşiklerin HMGR enziminin aktifliğinde önem arz eden Glu559, Cys668, Lys691 ve Lys692 kalıntıları ile etkileşimler oluşturarak enzim inhibisyonunda rol alabilecekleri belirlenmiştir.

Abstract

This study examines olive oil production and pomace management in Albania within the context of sustainable agriculture. The sector comprises approximately 500 processing plants, with over 95% employing three-phase extraction technology at capacities of 2–3 tons of olives per hour. Olive pomace, the main by-product, has been collected at nearly full efficiency in recent years, enabling secondary oil recovery of 1.5–2.0%. These practices contribute to Albania's emerging circular bioeconomy. Key challenges include wastewater disposal and the need for improved valorization of by-products into energy and fertilizers. Strategic interventions to optimize extraction efficiency and implement environmentally sound waste management are essential for reducing ecological impacts and promoting sustainable growth in the national agro-industrial framework.
Keywords: Olive oil, pomace extraction, olive mill wastewater, Albania, sustainable agriculture

INTRODUCTION

Olive cultivation in Albania reflects the broader Mediterranean distribution of the species, thriving primarily in coastal and river valley regions within the Mediterranean climate zone, which covers 36.2% of the country's territory. This environment has supported the development of several native cultivars, classified into primary and secondary groups based on prevalence. Kalinjoti, Kokërrmadh Berati, and Bianco di Tirana dominate as primary cultivars, while others maintain localized importance in specific regions (Topi, 2011; Topi et al., 2017).
For analytical and administrative purposes, olive plantations are grouped into four regions:
Southern Coastal Region (12,700 ha; 28%) – hilly terrain, high temperatures, limited irrigation.
Adriatic Region (18,300 ha; 36%) – low-altitude hills and plains, high yields, premium oil quality.
Pre-Adriatic Region (18,000 ha; 35.4%) – mountainous terrain with challenging pedo-climatic conditions.
Inland Region (210 ha; 0.6%) – microclimatic adaptation, offering opportunities for crop diversification under climate change (MAFCP, 2009).
This geographical diversity underpins Albania's olive oil sector, which has evolved from traditional practices to modern extraction technologies. Understanding this transition and its environmental implications is essential for developing sustainable strategies in the agro-industrial framework.

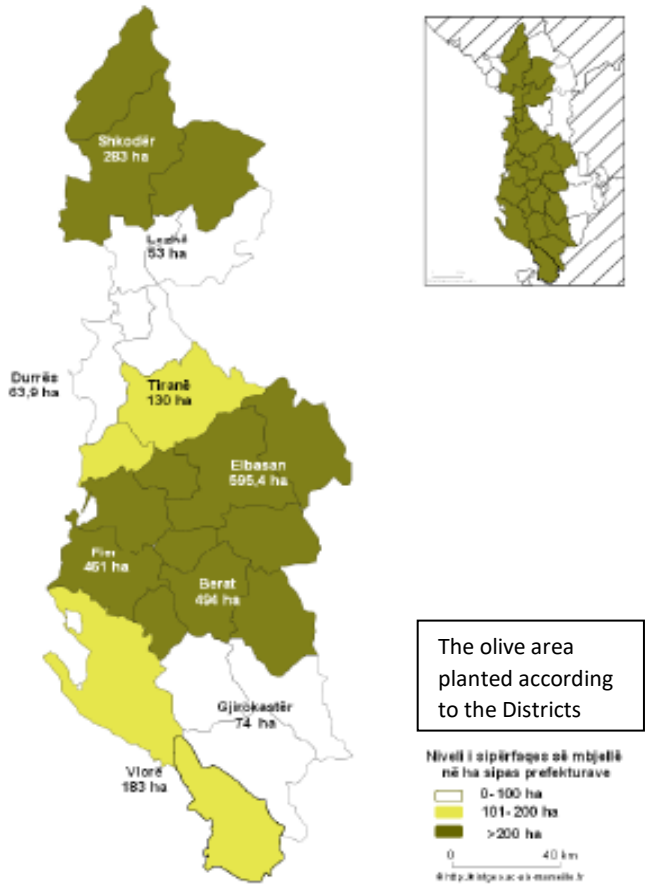

Figure 1: Regions of olive plantations (Source: **MAFCP, 2009**).

OLIVE PRODUCTION AND CONTRIBUTION TO THE NATIONAL ECONOMY

Olive cultivation has been a cornerstone of Albanian agriculture for millennia. During the socialist period (1947–1990), agriculture operated under a centralized economy, with olive plantations established primarily on degraded soils in hilly areas. Agronomic interventions during this era expanded plantations across western Albania, from Konispol to Shkodra, significantly increasing yields. Production rose from approximately 12,000 tons annually in the 1950s to 26,700 tons in the early 1980s (FAOstat, 2024).

Following the transition to a market economy in the early 1990s, new economic incentives and subsidies stimulated olive cultivation, resulting in a steady increase in production. Between 1992 and 2008, annual yields averaged around 35,000 tons. Over the past two decades, olive production has flourished, with the highest efficiency recorded in Berat, Vlora, and Mallakastra. Today, the olive oil processing industry is well established in central Albania (Topi et al., 2022). Table olive production has also grown, ranging from 18,000 to 29,000 tons in recent years (IOOC, 2024).

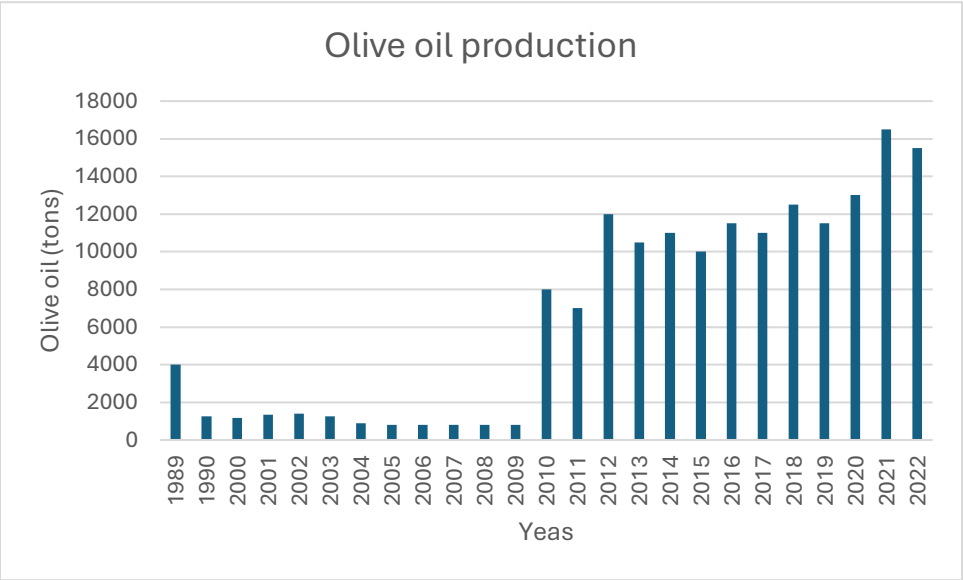

Figure 2. Olive oil production during the period 1989-2022 (FAOStat, 2024).

According to FAOSTAT, olives rank ninth among Albania's top agricultural commodities by production volume and fourth by gross production value. In 2022, olive fruit production reached approximately 157,710 tons, yielding 15,500 tons of olive oil. Cultivation spans 50,404 hectares across 90,000 small farms, with an average productivity of 2,333 kg/ha (INSTAT, 2024). The sector contributes an estimated $125.5 million to domestic production, positioning Albania 15th globally in olive production value (FAOstat, 2024).

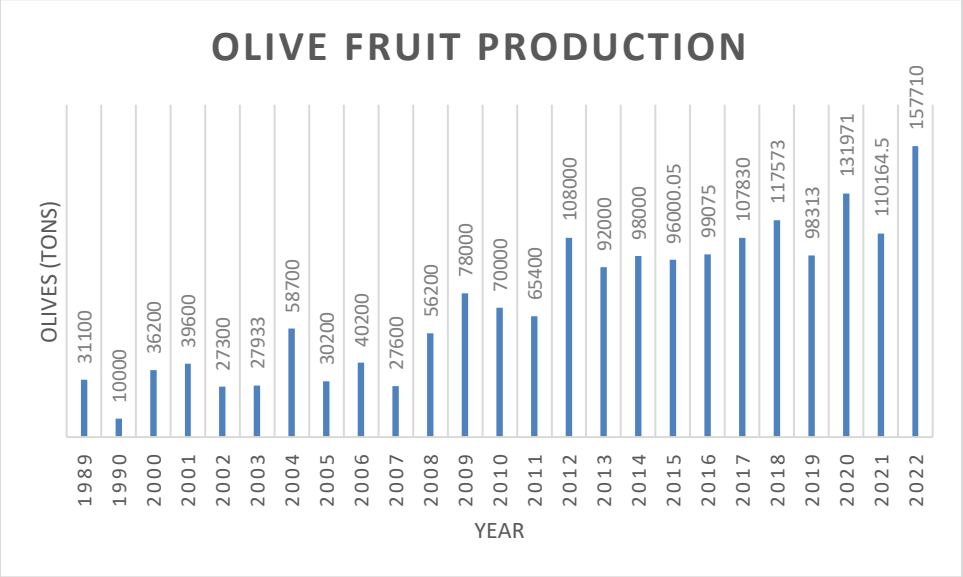

Figure 3. Olive production during 1989-2022, in Albania (Source: FAOStat, 2024).

OLIVE CULTIVATION AND THE ENVIRONMENTAL IMPACT

The expansion of olive cultivation in Albania has generated environmental concerns, primarily soil degradation and water pollution from olive mill waste (Beaufoy, 2000; Ibrahem et al., 2005). Olive terraces dominate many Mediterranean landscapes, including Albania, where large monocultures often prevail (Velo & Topi, 2017). Although olive trees require relatively low inputs, cultivation practices vary widely and can be grouped into three categories:

Low-input traditional plantations and scattered trees

Intensified traditional plantations,

Intensive modern plantations of small tree varieties (Beaufoy, 2000).

Traditional low-input systems offer high biodiversity and landscape value, improving water management and reducing soil erosion. However, these systems are economically marginal and vulnerable to abandonment. Fertilizer use is minimal, indirectly promoting Good Agricultural Practices and enabling organic production potential (Topi et al., 2019).

Conversely, intensified plantations are associated with soil erosion, water depletion, and pollution from agrochemicals. Erosion is most severe on steep slopes lacking terraces and is exacerbated by intensive tillage, which reduces soil organic matter and increases vulnerability to rainfall (Topi et al., 2014). Sustainable management practices, including terrace maintenance and reduced tillage, are essential to mitigate these impacts.

OLIVE OIL PROCESSING INDUSTRY AND THE ENVIRONMENTAL IMPACT

Olive oil extraction in Albania is highly seasonal, with milling operations concentrated within a 90-day period (October–December). Approximately 500 processing plants operate nationwide, contributing significantly to rural employment. The industry predominantly uses three-phase centrifugation technology (>95%), with capacities of 2–3 tons of olives per hour per plant.

Table 1: Key figures on olive by-products related to the extraction technology

Production process	Input	Amount of input	Output	Amount of output
Pressing	Olives	1 t	Oil	200kg
	Washing water	0.1-0.12 m^3	OH, OMW	400 kg 400-600 l
Three-phase decanter	Olives	1 t	Oil	200kg
	Washing water	0.1-0.12 m^3	OH,	500-600 kg
	Fresh water for the decanter	0.5-1.0 m^3	OMW	1000-1200 l
Two-phase decanter	Olives	1 t	Oil	200kg
	Washing water	0.1-0.12 m^3	OH, OMW	400 kg 85-110 l

Endnote 1: OH-Olive Husk; OMW-Olive Mill Waste (Caputo et al. 2007)

Olive oil production generates substantial by-products: solid residues (olive husk, OH) and liquid residues (olive mill wastewater, OMW). The proportion of these by-products varies by extraction method, ranging from 40% OH and 40% OMW in traditional batch systems to 50% OH and up to 95% OMW in continuous centrifugation systems (Caputo et al., 2007). OMW poses a major environmental challenge due to its high organic load (BOD 23–100 g/L), which is 25–80 times greater than municipal wastewater (Schmidt & Knobloch, 2000). Discharge into rivers reduces biodiversity, suffocates benthic organisms, and contaminates groundwater (Niaounakis & Halvadakis, 2006; Anastasiou et al., 2011).

According to the olive oil production data and Caputo's study calculation, processed by-products amount to approximately 190 × 10^5 kg of OH and 250 × 10^5 kg of OMW. Given the geographical distribution of the Olive Oil Extraction Industry in Albania, implementing environmentally friendly waste disposal schemes is challenging. Currently, olive pomace, the primary by-product of extraction, has been collected at nearly 100% efficiency over the past 2–3 years, especially from the ONER LABATE plant. The volume of pomace varies annually depending on olive fruit yield. Olive oil recovery from pomace ranges between 1.5–2.0%, generating significant economic revenue. The valorization of solid by-products into energy and fertilizer has increased profitability and exemplifies the circular bioeconomy.

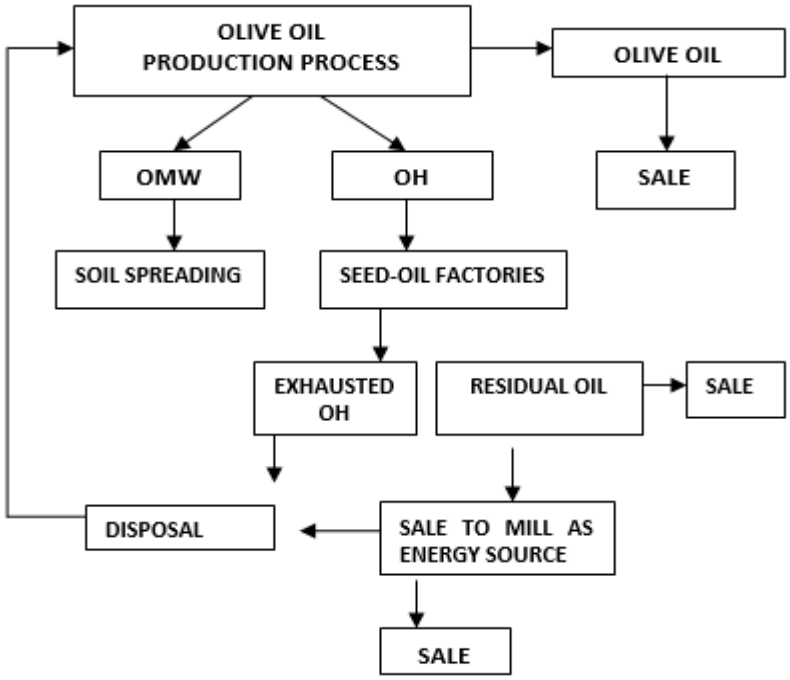

Figure 4: Current disposal scenario (Caputo et al., 2003)

Recent improvements include nearly complete collection of olive pomace for secondary oil recovery (1.5–2.0%) and its valorization into energy and fertilizers, supporting Albania's circular bioeconomy. However, wastewater management remains insufficient, requiring urgent implementation of environmentally sound disposal and treatment strategies.

Strategic implications include the need for improved wastewater management and enhanced extraction efficiency. Because of high organic loads and the presence of toxic substances like polyphenols, groundwater and surface water contamination is evident in regions where the Olive oil industry operates.

CONCLUSIONS AND RECOMMENDATIONS

Olive cultivation and oil production in Albania play a critical role in the national agro-industrial sector and offer significant potential for sustainable development. However, environmental challenges persist, primarily due to inadequate management of olive mill wastewater (OMW) and olive husk (OH). Current practices—such as effluent discharge into surface waters and husk combustion—contribute to soil and water contamination and localized air pollution.

To address these issues and promote sustainability, the following measures are recommended:

Environmental Management needs prohibit direct discharge of OMW into rivers and surface waters. Implement controlled land application of vegetation water, adhering to safe limits (≤800 m^3/ha), as supported by prior research.

By-Product Valorization policy to encourage conversion of olive husk into bioenergy and animal feed to reduce air pollution and enhance resource recovery. Promote circular economy models through public–private partnerships and targeted incentives. Support organic and integrated production systems to minimize the use of agrochemicals. Prevent abandonment of traditional low-input plantations that preserve biodiversity and landscape value.

Establish mandatory reporting and monitoring of effluent disposal practices at olive mills. Create regional inspection units to enforce compliance with environmental standards. Fund research on innovative wastewater treatment technologies and soil restoration practices. Foster collaboration between academia, industry, and government to develop cost-effective waste management solutions.

By implementing these strategies, Albania can strengthen its circular bioeconomy, reduce environmental risks, and position olive farming as a model for sustainable land use in the Mediterranean region. These findings highlight the sector's potential for sustainable growth and resource recovery within the national agro-industrial framework.

Özet

Bu çalışmada Düzce Üniversitesi Konuralp Yerleşkesinde yayılış gösteren yaban arısı tür çeşitliliği ve bunların hangi bitki gruplarının tozlaşmasında rol oynadıkları belirlenmiştir. Arazi çalışmalarında iki farklı yöntem kullanılmıştır. Birinci yöntemde yerleşkedeki bitki vejetasyonun çiçeklenmesi yıl boyunca takip edilerek yaban arısı görülen alanlardan atrap kullanılarak erkek ve dişi bireyler yakalanmıştır. Bu esnada arı yakalanan bitkilerin fotoğrafları çekilmiş ve bitkinin herbaryum örneği alınmıştır. İkinci yöntemde yerleşke içerisinde farklı noktalara tuzak yuvalar bırakılmıştır. Bu yuvalar düzenli olarak kontrol edilerek hangi arı türlerinin bunları kullandığı belirlenmiştir. Çalışma sonunda Düzce Üniversitesi Konuralp yerleşkesinde atrap ve doğrudan gözlem ile Apidae, Andrenidae, Bombidae, Colletidae, Halictidae, Xylocopidae familyalarına ait 15 farklı cinse ait 43 farklı yaban arısı türü tespit edilmiştir. Bu arıların yerleşke içerisinde Apiaceae, Asteraceae, Asparagaceae, Boraginaceae, Brassicaceae, Cistaceae, Convolvulaceae, Fabaceae, Hypericaceae, Lamiaceae, Plantaginaceae, Rosaceae familyalarından 39 bitki türü ile ilişkili olduğu gözlenmiştir. Tuzak yuvaları ise Colletidae, Megachilidae familyalarından birer türün kullandığı tespit edilmiştir. Elde edilen bulgulara göre kısa dilli yaban arısı türleri Apiaceae, Asteraceae, Brassicaceae, Cistaceae, Convolvulaceae, Hypericaceae, Plantaginaceae familyasından türleri, uzun dilli arılar ise Boraginaceae, Fabaceae, Lamiaceae türlerinin polinasyonunda daha fazla rol oynamaktadır. Yerleşke içerisinde monokültüre dayalı peyzaj uygulamalarının olduğu alanlarda arı çeşitliliğinin azaldığı, doğal haline bırakılan sahalarda ise bitki çeşitliliğine paralel olarak yaban arısı çeşitliliğinin arttığı gözlenmiştir.

Research on Wild Bee Diversity and Its Effects on Pollination at Düzce University Konuralp Campus

Abstract

The aim of this study was to determine the diversity of bee species distributed on the Konuralp Campus of Düzce University and to determine the plant groups they pollinate within the campus. Two different methods were used in the field studies. First, male and female individuals were captured using a net in areas where bees were frequently observed, based on seasonal changes in vegetation. Herbarium samples were collected, and the photographs were also taken from each plant species. In the second method, trap nests were placed at various locations within the campus. These nests were regularly inspected to determine which bee species were using them. As a result of the study, 43 different bee species belonging to 15 different genera belonging to the families Apidae, Andrenidae, Bombidae, Colletidae, Halictidae, and Xylocopidae were identified on the Konuralp campus of Düzce University. These bees were observed to associate with 39 plant species within the campus from the families Apiaceae, Asteraceae, Asparagaceae, Boraginaceae, Brassicaceae, Cistaceae, Convolvulaceae, Fabaceae, Hypericaceae, Lamiaceae, Plantaginaceae. One species from the families Colletidae and Megachilidae, were found to use the trap nests. According to the findings, short-tongued bees play a greater role in pollinating species from the Apiaceae, Asteraceae, Brassicaceae, Cistaceae, Convolvulaceae, Hypericaceae, Rosaceae, and Plantaginaceae families, while long-tongued bees play a greater role in pollinating species from the Boraginaceae, Fabaceae, and

Lamiaceae families. Bee diversity decreased in areas with monoculture-based landscaping practices within the campus, while bee diversity increased in areas left to their natural state, parallel to plant diversity.

GİRİŞ

Arılar, Hymenoptera takımında Apoidae üst familyasının Apiformes grubunu oluşturan böceklerdir. Yeryüzünde, Antartika kıtası hariç en az 20.000 arı türünün olduğu düşünülmektedir; (Potts ve ark, 2015). Ascher, J. S. ve Pickering, J. (2019) yaptığı bir çalışmada Türkiye'de 1662 arı türünün varlığını rapor edilmiştir. Özbek (2002)'e göre de ülkemizin iklim koşulları, topoğrafik yapısı, coğrafik konumu ve zengin bitki örtüsüne bağlı olarak yaklaşık 2000 yaban arısı türünün yaşadığı tahmin edilmektedir. Ancak ülkemizde yaban arıları oldukça ihmal edilmiştir. Oysa, arılar yabani bitki çeşitliliğinin korunması (Potts ve ark., 2010) ve yayılması sayesinde erozyonun önlenmesi ve azaltılmasında (Özbek, 2002), tarımsal üretimin (Gallai ve ark., 2009) korunmasında hayati öneme sahiptir. Bu nedenle arılar doğada anahtar tür olarak kabul edilmektedir (Özbek, 2002 ; Michener, 2007). Genel olarak insanlar bal arısının (*Apis mellifera*) ürettiği bal, balmumu, arı sütü, arı zehri vb. ürünlere ilgi duymakta ve arıların tek faydasının bu olduğu düşünülmektedir. Ayrıca bal arısını, geniş yayılım alanı, beslenme davranışı ve etkili tozlaşma yeteneği sayesinde en önemli tozlayıcı tür olarak da kabul etmektedir. Ancak, çiçekli bitki türlerinin büyük bir bölümünün polinasyonunda bal arılarının hiçbir rolü bulunmamaktadır (Garibaldi ve ark. 2013; Hung ve ark. 2018). Yapılan çalışmalar göstermiştir ki, birçok çalı, küçük ağaç ve ot türleri ile birçok yabani çiçek türünün polinasyonu yaban arılarına bağlıdır. Bahçe çiçekleri, çoğu meyve ve sebze, keten, pamuk gibi birçok tekstil bitkisi ile yonca gibi başlıca yem bitkileri arılar tarafından tozlaşmaktadır (Michener, 2007; Özbek, 2018).

Son on yıllık gözlemlere göre bal arıları ve yaban arılarının polinasyona yaptıkları katkının azaldığı düşünülmektedir (Kevan ve Viana, 2003). Bu kaybın sebebi olarak monokültür tarım uygulamaları, arı hastalık ve parazitlerinin artışı, yoğun pestisit kullanımı, şehirleşme, yaban alanlarının parçalanmasına sebep olan yanlış arazi kullanımı ve iklim krizi gösterilmektedir (Stanton ve ark., 2018; Forister ve ark. 2019; Wan ve ark., 2021; Birkenbach ve ark. 2024). Özbek'in (2002) Türkiye'de yaptığı gözleme göre, Türkiye'de yaban arılarının yoğunluğunun son 30 yılda üstel bir şekilde azaldığı ve bazı arı türlerinin muhtemelen yok olma tehlikesiyle karşı karşıya veya yok olma eşiğinde olduğu vurgulamaktadır. Örneğin, 1970'li yıllarda oldukça bol bulunan önemli bir yonca polinatörü olan *Melitta dimidiata* ile birlikte, yonca için son derece önemli olan *Melitta leporina*, *Rhophitoides canus* ve *Melitturga clavicornis* popülasyonlarında büyük bir düşüş yaşandığını bildirmiştir (Özbek, 1979). Bu durumu göz önünde bulundurarak, Türkiye topraklarında hâlâ mevcut olan yabani polinatör arı türlerini araştırmak ve hangi bitki gruplarıyla ilişkili olduklarını tanımlamak gereklidir.

Bu yüksek lisans çalışmasında, Düzce Üniversitesi Konuralp Yerleşkesinde yayılış gösteren yaban arısı populasyonlarını tespit edilerek ve bunların yerleşke içerisinde hangi bitki gruplarının polinasyonunda rol oynadığı ortaya konmuştur.

MATERYAL VE METOT

İlk arı örnekleri Mart ayında yakalanmaya başlanmıştır. Örnekleme ve gözlemler yerleşkedeki vejetasyonun mevsimsel değişimine göre ancak temmuz ayının sonuna kadar devam edebilmiştir. Temmuz ayından sonra vejetasyonun kurumasından dolayı arazi çalışmalarına devam edilememiştir. Eylül ayından sonra sadece doğrudan gözlem yapılmıştır. Çalışmaya başlamadan önce yerleşke içerisinde arı çeşitliliğinin yoğun olduğu, çiçeklenmenin yüksek olduğu alanlar belirlenmiştir. Bu noktalar düzenli aralıklarla (her 7-10 günde bir) ziyaret edilerek arı örnekleri yakalanmış, eğer aynı noktadan aynı türe ait birden fazla birey yakalandıysa alandaki popülasyonun korunması adına geri salınmıştır. Sadece söz konusu tür/türlerin yıl boyunca aktif oldukları uçuş dönemleri ve polinasyon yaptıkları bitkiler ile ilgili kayıtlar alınmıştır. Arılar atrap ile yakalanıp, ağız aspiratörü ile 150 ml plastik tüpler (Falcon tüp) içerisine aktarılmıştır. Bu tüpler laboratuvara getirilene kadar el tipi buzluklar içerisinde muhafaza edilmiştir. Laboratuvar getirilen arı örneklerinden her grubu temsilen birkaç birey etil asetat ile öldürülüp, iğnelenmiştir. Yakalanan arılar Michener (2007)'deki taksonomik tür veya cins tayin anahtarları yardımıyla teşhisleri yapılmıştır. Daha sonra bu örnekler ahşap kutular içerisinde muhafaza edilmiştir. Ayrıca arı örneklerinin kameralı mikroskop yardımıyla fotoğrafları çekilmiştir. Ayrıca yakalanan arıların polen topladığı bitkilerden herbaryum materyali alınmış ve bitkilerin fotoğrafları çekilmiştir.

Yaban arısı çeşitliliğini tespit etmek için bir başka yöntem olarak tuzak yuvalar kullanılmıştır. Tuzak yuvalar için internetten 6-8 mm çapında 20 cm'lik bambu ve saz pipet satın alınmıştır. *Xylocopa* gibi büyük arı türleri için *Arundo donax* (Poaceae) bitkisinden 15 mm çapında, 20-25 cm'lik kısa parçalar hazırlanmıştır. Beş adet *A. donax*, 10'ar adet bambu ve saz pipet olacak şekilde 15 cm çapında, 40 cm'lik PVC bir boru içerisine yerleştirilmiştir. Yuvalar yerleşkenin farklı noktalarına yerden en az 150 cm yüksekte bir yere ve giriş kısmı güneye bakacak şekilde sabitlenmiştir. Bütün yuvalar mayıs ayının ilk haftası, alanda belirli yerlere bırakılmıştır. Düzenli aralıklarla kontrol edilen yuvalardan dolu pipetler alınıp laboratuvarda plastik kutular içerisinde takip edilmiştir. Yuvadan çıkış yapan arılardan erkek ve dişi bireylerden örnek alınıp etil asetat ile öldürüldükten sonra, iğnelenmiştir. Eylül ayında tuzak yuvaların tamamı alandan toplanmıştır.

BULGULAR ve TARTIŞMA

Yakalanan arı örneklerinin hepsi Michener (2007)'de belirtilen cins tayin anahtarlarına göre tanımlanmıştır. Aynı cinsin morfolojik olarak birbirinden çok farklı olan üyeleri ayrı türler olarak değerlendirilmiştir. Çalışma sonunda yerleşke sahasında yedi yaban arısı familyasına ait 43 türün varlığı tespit edilmiştir. Bu familyalar ve yakalanan arı cinsleri Tablo 1'de verilmiştir. En fazla tür Andrenidae familyasının *Andrena* cinsine aittir. Yerleşkemizde 15 *Andrena* türünün yaşadığı, yine aynı familyadan *Panurgus* cinsinin bir türünün daha bulunduğu tespit edilmiştir. Kum arıları ya da soliter kazıcı arılar olarak bilinen *Andrena* cinsi, Dünya'da alttürleri ve sinonimleri de içeren yaklaşık 3000 taksonla arı cinsleri arasında en geniş grubu oluşturur. Gerçek tür sayısının 1500'ün üzerinde olduğu düşünülmektedir (Dubitzky ve ark., 2010). Yerleşke içerisinde tür sayısı bakımından en kalabalık ikinci familya Halictidae'dir. Çalışma sonunda Halictidae familyasından dört cinsten toplam dokuz tür tespit edilmiştir.

Michener, (2007) kısa dilli arıların, sığ yapılı çiçeklerden nektar alırken, daha derin yapılı çiçeklere sahip bitki türlerinin ise uzun dilli arılar tarafından tercih edildiğini bildirmiştir. Kendi gözlemlerimizde bu bilgiyle uyumludur. Yerleşkede yakalanan kısa dilli arı grupları *Andrena, Panurgus, Lasioglossum, Halictus, Hylaeus, Sphecodes, Systropha* türlerinin yerleşkedeki sığ çiçek yapısına sahip Apiaceae, Asteraceae, Brassicaceae, Cistaceae, Convolvulaceae, Hypericaceae, Plantaginaceae familyalarını ziyaret ettiği gözlemlenmiştir. Yerleşkede uzun dilli arıların (*Anthophora, Amegilla, Eucera, Ceratina, Xylocopa, Megachile, Osmia, Anthidium, Bombus*) türlerinin derin çiçek yapısına sahip Boraginaceae, Fabaceae, Lamiaceae türlerini tercih ettiği tespit edilmiştir. Yerleşkenin kuzey ve kuzey doğu bölümlerinde ağaçlandırma sahası ve hurda biriktirme alanı olarak değerlendirilmektedir. Bu nedenle peyzaj uygulaması hiç yapılmamıştır. Buralarda bölgenin doğal vejetasyonunu yansıtan bitki örnekleri bulunmaktadır. Yapılan gözlemlerde bu bölgelerde bitki ve yaban arısı tür çeşitliliğinin diğer sahalara göre daha fazla olduğu gözlenmiştir. Yerleşke içerisinde bal arısı popülasyonlarına da rastlanmıştır. Ancak bu çalışmada bal arılarının besin tercihleri değerlendirilmemiştir.

Yerleşkedeki yaban arılarının 13 familyadan 39 bitki türünün çiçeklerinden nektar ve polen topladığı tespit edilmiştir. Bitki türlerinin familya ve tür isimleri Tablo 1 'de verilmiştir. Asteraceae 13 tür ile yerleşkede en yaygın grup ve arıların en çok tercih ettiği bitki familyasıdır. Bunu 5'er tür Brassicaceae, 4 tür ile Fabaceae ve Lamiaceae, 3 tür Boraginaceae, 2 tür Convolvulaceae takip etmektedir. Diğer familyalardan ise sadece birer tür yer almaktadır.

Mart ayından itibaren uzun dilli arılardan *Bombus* (Bombidae), *Eucera* (Apidae), *Anthophora* (Apidae) ve *Ceratina* (Xylocopidae), *Xylocopa* (Xylocopidae) türleri ortaya çıkmıştır. Kısa dilli arılardan ise *Andrena* (Andrenidae), *Panurgus* (Andrenidae), *Lasioglossum* (Halictidae) türleri görülmüştür. Arıların bu dönemde polen ve nektar topladığı bitki türleri *Taraxacum laevigatum* (Asteraceae), *Taraxacum serotinum* (Asteraceae), *Lamium p*urpureum (Lamiaceae), *Ornithogalum pyrenaicum* (Asparagaceae), *Veronica* sp. (Plantaginaceae), *Erysimum repandum* (Brassicaceae), *Raphanus raphanistrum* (Brassicaceae)'dur. Nisan ayında kısa dilli arılardan *Andrena*, *Lasioglossum*, *Sphecodes* (Halictidae) aktivitesi devam ederken, uzun dilli gruplardan *Anthophora*, *Bombus*, *Eucera*, *Ceratina*, *Xylocopa* cinslerinin yerleşkedeki *Crepis s*ancta (Asteraceae), *Crepis setosa* (Asteraceae), *Taraxacum bithynicum* (Asteraceae), *Raphanus rapistrum* (Brassicaceae), *Rapistrum rugosum* (Brassicaceae), *Nepeta nuda* (Lamiaceae) türlerini ziyaret ettiği görülmüştür. Mayısta ise kısa dilli arı gruplarından *Andrena*, *Lasioglossum* cinslerine ilaveten *Halictus* (Halictidae) türleri ortaya çıkmıştır. Ayrıca Fabaceae ve Lamiaceae bitki familyalarına ait farklı türlerin yaygınlaşmasıyla beraber Megachilidae familyasının *Anthidium*, *Megachile* ve *Osmia* türleri uçmaya başlamıştır. Mayıs ayında yerleşkede *Andrena* ve *Lasioglossum*'lar halen aktif haldedir. Haziran temmuz döneminde ise *Andrena* türleri ortadan kaybolmuş, *Halictus*, türleri daha baskın hale gelmiştir. Bunun yanında *Lasioglossum, Systropha* (Halictidae), *Amegilla* (Apidae), *Osmia* türlerinin aktivitesi devam etmiştir. Vejetasyonunda ise *Lathyrus laxiflorus* (Fabaceae), *Lotus corniculatus* (Fabaceae), *Stachys iberica*

(Lamiaceae), *Stachys thirkeii* (Lamiaceae), *Echium vulgare* (Boraginaceae), *Sophora jaubertii* (Fabaceae), *Crepis setosa* (Asteraceae), *Crepis reuteriana* (Asteraceae), *Hypericum montbretii* (Hypericaceae), *Convolvulus cantabrica* (Convolvulaceae), *Convolvulus arvensis* (Convolvulaceae), *Carduus nutans* (Asteraceae), *Filipendula vulgaris* (Rosaceae), *Sonchus asper* (Asteraceae), *Anchusa officinalis* (Boraginaceae), *Raphanus raphanistrum* (Brassicaceae), *Knautia degenii* (Caprifoliaceae) türleri daha yaygın olarak görülmektedir. Temmuz ayından itibaren bu bitkilere ilave olarak *Centaurea iberica* (Asteraceae), *Echium italicum* (Boraginaceae), *Cichorium intybus* (Asteraceae), *Digitalis* sp. (Plantaginaceae) türleri de görülmeye başlamıştır (Tablo 2, Şekil 1 ve 2).

Yerleşkenin peyzaj alanlarında otsu ve çiçekli bitki olarak çoğunlukla *Trifolium* (Fabaceae) türleri kullanılmıştır. Bu sahalarda *Trifolium* populasyonlarının arasında Asteraceae' den *Taraxacum*, *Crepis*, *Sonchus* türleri, Boraginaceae'den *Anchusa* türlerine de rastlanmaktadır. Trifolium türlerinin yeşil kalabilmesi için düzenli bakım işlemleri yapılmaktadır. Böylece arılara sürekli polen ve nektar kaynağı ortaya çıkmıştır. Bu sayede bazı küçük boyutlu *Andrena* ve *Lasioglossum* türlerine yerleşkenin büyük bir kısmında tüm sezon boyunca aktif oldukları gözlenmiştir.

Çalışma sonunda alana bırakılan tuzak yuvalar *Osmia* (Megachilidae) ve *Hylaeus* (Colletidae) cinslerine ait birer türün kullandığı tespit edilmiştir. Büyük arı türleri tuzak yuvalara gelmemiştir.

Tablo 1. Yerleşkede yakalanan yaban arılarının familya, cins ve tür sayıları ile ilişkili oldukları bitki familyaları ve sayısı

Yaban arısı familyaları	Yaban arısı cinsleri	Yaban arısı tür sayısı

SONUÇ

Yapılan bu çalışma sonucunda Düzce Üniversitesi Konuralp yerleşkesinin bal arısı *Apis mellifera* dışında 43 farklı yaban arısı türüne ev sahipliği yaptığı belirlenmiştir. Bu türlerin 39 farklı çiçekli bitki türünün tozlaşmasıyla doğrudan ilişkisi olduğu ortaya konmuştur. Bu çalışma ile yerleşke sahasının polinatör-bitki çeşitliliği ortaya çıkartılmıştır. Ancak yerleşke sahasında uzun süreli yapılacak gözlemler ile iklim değişikliği ve insan aktivitesinin yaban arısı popülasyonlarına etkisinin takip edilmesi önemlidir.

TEŞEKKÜR

Bu çalışmanın verileri Tamasi Olajide Fadare'nin Düzce Üniversitesi Biyoloji Enstitü anabilim dalında yürüttüğü yüksek lisans tez çalışmasından elde edilmiştir.

Abstract

Medicinal plants are a rich source of bioactive compounds for different fields, especially health. *Viburnum opulus*, also known as European cranberrybush or Gilaburu, is a plant native to Europe, northern Africa and central Asia with its creamy white flowers and red berries in spring. As a component of green chemistry, deep eutectic solvents (DESs) have attracted attention in recent years due to their superior properties over traditional solvents. DESs consisting of two or more components have properties such as low volatility, low melting point, low flammability, low toxicity, and high biocompatibility. DESs are used in the extraction of highly biologically active metabolites found in different parts of plants. In this study, dried *V. opulus* fruit was extracted with DESs. The resulting extracts were examined for total phenolic compounds, total carbohydrate content, anthocyanin content, antioxidant activity and antimicrobial activity, and compared with aqueous extracts using the same methods. The results obtained are promising in terms of DESs extracting biometabolites and exhibiting activity shown above 100 mg Trolox/10 g antioxidant capacity in various DESs. DES extracts also showed high antimicrobial activity with the highest being Choline Chloride:Acetic Acid DES extract having around 45 mm inhibition zone diameter against *Candida albicans* fungi, 16.5 mm zone for gram positive *Staphylococcus aureus* and 23.5 mm zone for gram negative *Escherichia coli* bacteria. DESs, which are also the subject of active pharmaceutical ingredient studies, have the potential to determine the content of medicinal plants and incorporate them into various biomedical applications.

Keywords: *Viburnum opulus*, deep eutectic solvents, extraction, antioxidant activity, antimicrobial activity

INTRODUCTION

Medicinal plants contain various natural bioactive compounds, primary and secondary metabolites and compounds that provide different activities (Goławska et al., 2023). *Viburnum opulus* is the scientific name for Gilaburu plant in the genus *Viburnum* L., which is in the family Adoxaceae. It is known by many names, including European guelder, guelder rose, rose ebru, rose elder, European cranberrybush, water elder, cramp bark, cherry wood, and snowball tree (Kajszczak et al., 2020). There are many uses for the plant *V. opulus*: it is valuable for decoration, medicine and food (Goławska et al., 2023). The plant's cream-white flowers, which bloom in late May and June, measure 7 to 10 cm in length (Akbulut et al., 2008). The fruit of the plant is indirectly edible due to astringent taste and is a dark red colour (Levent Altun et al., 2008; Gülada et al., 2024). This fruit ripens in September and October. It is similar in size and colour to a cranberry, but becomes more translucent when fully ripe (Akbulut et al., 2008). In Russia, Ukraine and many Siberian countries, the fruits of this plant with a bitter taste are used as a filling and sauce in cakes and drinks (Česonienė et al., 2010). In Turkey, this plant grows in Central Anatolian states such as Kayseri, Bursa, Sakarya, Ankara, Tokat, Trabzon and Çorum (Akbulut et al., 2008). In the Central Anatolia region of Turkey, especially in Kayseri, this plant, whose local name is “Gilaburu”, is traditionally consumed mostly as fruit juice (Gülada et al., 2024). The consumption of this beverage by residents of the central Anatolian region of Turkey is believed to help prevent kidney and stomach problems (Akbulut et al., 2008). Recent studies have

demonstrated the potential of using *V. opulus* fruits in the development of new foods, such as desserts, yoghurt, liqueurs, beer, and vinegar (Ozrenk et al., 2020).

As reported by many researchers, phenolic acids, proanthocyanidins, anthocyanins, saponins, essential oils, and carotenoids have been detected in *V. opulus* fruits. These compounds confer several biological properties, enhance blood sugar uptake in diabetic patients and improve the lipid metabolism (Česonienė et al., 2010; Goławska et al., 2023). *V. opulus* has health benefits due to its bioactive components, including phenolic compounds, carotenoids, vitamin C, triterpenes, essential oils, iridoids, saponins and dietary fibre (Polka et al., 2019). Phenolic compounds are vital to both plants and humans due to several biological activities like anti-inflammatory, antioxidant and anticancer (Goławska et al., 2023). In addition, several *in vitro* studies have shown antioxidant, antimicrobial, anti-obesity, anti-diabetic, and anti-inflammatory activities of *V. opulus* (Gülada et al., 2024; Kajszczak et al., 2020). Antibacterial effects have been shown to be possessed by *V. opulus* against various pathogenic Gram-positive and Gram-negative bacteria (Goławska et al., 2023). Medicinal uses are one of the many applications of this plant. Traditionally, *V. opulus* juice has been used to treat ailments such as coughs, tuberculosis, colds, diabetes, ulcers, liver disease, and hypertension (Kajszczak et al., 2020; Levent Altun et al., 2008).

Conventional organic solvents, such as methanol, ethanol, benzene, chloroform, hexane and acetone, are known for being toxic, corrosive, highly volatile and non-biodegradable. Due to these disadvantages, studies on green chemistry solvents have become popular (Huang et al., 2025). In recent years, there has been an increasing interest in deep eutectic solvents (DESs) in many disciplines such as various biological sciences and pharmaceutical sciences, especially extraction and formulation research due to their different advantages. The “eutectic” term, derived from the Greek word “eutektos” meaning “easy melting”, refers to a specific type of mixture that has a lower melting point than other combinations of the same components (Chevé-Kools et al., 2025). DESs with a new type of solvent typically contain a hydrogen bond acceptor (HBA) and hydrogen bond donor (HBD) or may contain a larger number of components, this generally occurs with stirring and heating of the components to obtain a homogeneous liquid. Also, they have several advantages such as higher biodegradability, less toxicity, and lower volatility (He et al., 2024).

The aim of this study is to reveal the biological potentials of extracts of *V. opulus* known traditionally as Gilaburu, with different choline chloride based DES systems and compare the results of total phenolic compounds, total carbohydrate content, anthocyanin content, antioxidant activity, and antimicrobial activity with aqueous extract.

MATERIALS AND METHODS

Total moisture content of *Viburnum opulus* fruit

For the determination of the total moisture present within the fresh samples of *Viburnum opulus*, 1 g of fruit sample was placed in total moisture analyzer (Mettler Toledo). A standard method for determining the moisture was utilized via the application of 90 seconds of 90°C temperature, 150 seconds of 120°C temperature and 105°C of temperature for the rest of the analysis. Total moisture content was calculated using the remaining dry weight (Ahn et al., 2014).

Preparation of the deep eutectic solvents

For the extraction process, three types of DES were prepared and used along with a standard water extraction for comparison. Types of DES preferred for extractions are ChCl:A, ChCl:G and ChCl:U (Table 1). The DES components for each system were mixed by magnetic agitation at 80 °C until a homogeneous and clear solvent system was formed (at least 1 h).

Table 1. DES components

DES Type	HBA	HBD	Molar Ratio
ChCl:AA (CCA)	Choline Chloride	Acetic Acid	1:2
ChCl:G (CCG)	Choline Chloride	Glycerol	1:2
ChCl:U (CCU)	Choline Chloride	Urea	1:2

Preparation and extraction of *Viburnum opulus* biomass

Prior to the extraction process, fresh *V. opulus* was dried for a week to get rid of its moisture content at a temperature of 40°C. Dried fruit samples were then reduced in size via the usage of an industrial blender, and then 50 µm-sized *V. opulus* samples were separated using a mesh sieve. Smaller sample sizes were preferred in order to better maximise the extraction efficiency. The *V. opulus* samples that are reduced in size were stored at 4°C temperature in a dark environment.

To reduce the viscosity of DES and increase the extraction efficiency, 30% water was used in the extraction process (Liu et al., 2022). Extraction was performed by using 1:20 biomass:solvent ratio in a shaking water bath at 50°C for 2 hours. After the extraction, the liquid phase was separated via centrifuge and vacuum filtration. Extracts were stored at 4°C temperature in a dark environment until the characterization.

Total phenolic contents of *Viburnum opulus* extracts

The Folin-Ciocalteu method was used to determine the total phenolic content. Gallic acid (Sigma-Aldrich) was used as a standard (Miceli et al., 2009). Folin-Ciocalteu reagent at 0.2 N was added of 100 µL of sample at 200 µL volume and was thoroughly mixed. After mixing, 2 mL of distilled water and 1 mL of 6% sodium carbonate (Na_2CO_3) solution (Merck) were added in and vortexed. The resulting mixture was left to its reaction for 2 hours at room temperature in the dark under constant shaking. After the color change was observed, solution was read against 765 nm wavelength using a spectrophotometer (Mettler Toledo). The same procedure was repeated for gallic acid to form a calibration curve, and the result was obtained as gallic acid equivalent (GAE).

Total carbohydrate contents of *Viburnum opulus* extracts

Dubois method was used for the determination of the total carbohydrate content. Glucose was used as a standard. Extract was divided into a glass tube at the amount of 0.5 mL. Following that 0.5 mL of 5% phenol solution was added along with 2.5 mL of sulphuric acid (Merck). Vortexing was used to make a homogenous solution. DESs and water used as a blank was subjected to the same procedures as extract. After a waiting period of 15 minutes, the solution had its absorbance measured in a spectrophotometer (Mettler Toledo) at 490 nm (Matsuhiro et al., 2009).

Anthocyanin contents of *Viburnum opulus* extracts

The total monomeric anthocyanin content was determined according to the AOAC Official Method 2005.02 using the pH differential method. Samples were diluted with pH 1.0 potassium chloride–hydrochloric acid buffer and pH 4.5 sodium acetate–hydrochloric acid buffer. Absorbance values were measured spectrophotometrically at 510 and 700 nm. The total monomeric anthocyanin content was expressed as cyanidin-3-glucoside equivalents (mg/L) and calculated using the standard formula provided by AOAC, based on the absorbance difference between the two pH conditions (AOAC, 2005).

Antioxidant activities of *Viburnum opulus* extracts

The antioxidant activity was measured in terms of free radical scavenging against the DPPH (2,2-Diphenyl-1-picrylhydrazyl) method (Baliyan et al., 2022). The extract was divided into glass tubes in 1 mL volume. On top of each sample, a DPPH solution of 0.1 mM was added in 3 mL volumes. The absorbance values were measured in a spectrophotometer (Mettler Toledo) at 515 nm wavelength. Found values were given in terms of Trolox equivalent.

Antibacterial activities of *Viburnum opulus* extracts

Kirby-Bauer disc diffusion technique was used for determining the antibacterial activity via resulting zone diameters in bacterial culture (Hudzicki, 2009). Gram positive bacteria *Staphylococcus aureus* (ATCC 6538) and the gram negative bacterium *Escherichia coli* (ATCC 25922) were used as bacterial strains in this procedure. Solutions containing both strains of bacteria were diluted to around the range of 0.6 optical density at 600 nm and were inoculated into Mueller-Hinton Agar (Merck) via the usage of spread-plate method. After 24 hours of incubation, the samples diluted at different concentrations were loaded into sterile antibacterial susceptibility (Oxoid) discs at the volume of 25 µL and diameter of 6 mm. Loaded discs were placed on agar plates containing bacterial strains. After incubation time of 24 hours at 37°C temperature, antibacterial inhibition activity was recorded by measuring the diameter of the zones around each disc. Gentamicin antibiotic was used as a positive control and sterile water was used as a negative control (Biemer, 1973).

Antifungal activities of *Viburnum opulus* extracts

Agar well diffusion technique was used for determining the antifungal activity via resulting zone diameters in fungal culture (EUCAST, 2020). The fungal strain used in this procedure was *Candida albicans.* For this *C. albicans* was incubated in PDA (Merck) and was adjusted to final concentrations of 10^5 in the medium, and then was poured into wells into petri dishes opened via the usage of 5 mm diameter hollow sterile glass rods. Each well was loaded with 100 µL samples and were incubated for 24 hours at 37°C temperature. Antifungal inhibition activity was recorded by measuring the diameter of the zones around each disc. Fluconazole antibiotic was used as a positive control and sterile water was used as a negative control for the procedure (EUCAST, 2020).

RESULTS AND DISCUSSION

Characterization of the bioactive compounds in extracts

Total moisture content of the fresh *Viburnum opulus* fruit used in extraction is found to be 82.69 %. Total carbohydrate content, total phenolic matter content, anthocyanin content and antioxidant activity (Trolox equivalent) were determined using spectrophotometric methods. These analyses were also applied to the DESs themselves. The results were compared with the aqueous extract data. The measured values are given in Table 2.

Total carbohydrate contents for CCA extract, CCG extract, CCU extract and aqueous extract are 3091 ± 395 µg glucose/g, 4167 ± 212 µg glucose/g, 3739 ± 487 µg glucose/g and 5348 ± 325 respectively. DES's effect on total carbohydrate measurements is minimal with 11.63 ± 0.87 µg glucose/g for CCA, 81 ± 2.54 µg glucose/g for CCG and 12.61 ± 1.13 µg glucose/g for CCU. The CCG solution showed higher contents for carbohydrates due to its glycerol content.

The extract's ability to reduce DPPH was analyzed via the color change and the control solution didn't change in color. Trolox equivalent antioxidant capacity for CCA extract, CCG extract, CCU extract and aqueous extract are 109.05 mg Trolox/10 g, 116.55 mg Trolox/10 g, 116.05 mg Trolox/10 g and 133.8 mg Trolox/10 g respectively, while the total phenolic contents for them are 0.214 ± 0.011 mg GAE/g, 0.224 ± 0.020 mg GAE/g, 0.208 ± 0.019 mg GAE/g and 0.210 ± 0.005 mg GAE/g. Observed antioxidant activity on DES other than CCG were negligible. CCG extraction solvent showed a high radical scavenging activity as itself. Antioxidant activity of the extracts is generally related to their high total phenolic content (Wojdyło et al., 2007).

Table 2. Bioactivity results of the extracts

Sample	Total carbohydrate contents (µg glucose/g)	Total phenolic contents (mg GAE/g)	Anthocyanin contents (mg/L)	Antioxidant capacity (mg Trolox/10 g) TEAC
CCA extract	3091 ± 395	0.214 ± 0.011	265.03	109.05
CCG extract	4167 ± 212	0.224 ± 0.020	148.24	116.55
CCU extract	3739 ± 487	0.208 ± 0.019	723.21	116.05
Aqueous extract	5348 ± 325	0.210 ± 0.005	220.11	133.8
CCA	11.63 ± 0.87	0.077 ± 0.001	ND	16.45
CCG	81 ± 2.54	0.301 ± 0.041	ND	71.8
CCU	12.61 ± 1.13	0.071 ± 0.020	ND	13.45
Water	ND	ND	ND	12.45

ND: Non detected

Phenolic acids are one of the most common bioactive compounds found in plants. They play a key role in growth, reproduction, and defence against several environmental stresses. Since ancient times, the food industry has widely applied the antioxidant activities of phenolic acids as preservatives. They also delay aging and lower the likelihood of developing life-threatening diseases (Ozrenk et al., 2020). Gülada et al. identified the phenolic contents of the methanolic extract of *V. opulus* fruit as quinic acid, cyanidin 3-glucoside and chlorogenic acid by HPLC-DAD (Gülada et al., 2024). The estimated phenolic content was 0.68–0.83 g/100 g fresh weight (FW) in *V. opulus* fruits grown in the Czech Republic, and 0.40–0.73 g/100 g FW in fruits from Russia. For fresh fruit from Turkey and Lithuania, the respective values were 0.62–0.99 g/100 g FW and 0.75–1.46 g/100 g FW (Polka et al., 2019). Ozrenk et al. (2020) biochemically and morphologically characterised 14 *V. opulus* genotypes from Gümüşhane, Turkey and found that total phenol content ranged from 696 to 830 mg gallic acid equivalent per 100 g fresh weight (Ozrenk et al., 2020). Česonienė et al. (2010) determined the amount of total phenolic matter of different genotypes of *V. opulus* between 753.0 and 1460.0 mg/100 g in their study (Česonienė et al., 2010). In another study, Sagdic et al. found that the total phenolic content was 131.99 ± 2.11 mg gallic acid equivalent (GAE)/g in the extract (Sagdic et al., 2006). In another study, total phenolics were detected as 3.51, 3.98 and 3.73 g GAE/100 g DW in the flowers, bark and fruits of *V. opulus*, respectively (Polka et al., 2019). Levent Altun et al. (2008) found the inhibitory percent of *V. opulus* water extract of branch, fruit, and leaf were 93%, 94% and 88%, respectively. The values of concentration at these antioxidant activities were 0.066, 0.064 and 0.4 mg/mL (Levent Altun et al., 2008).

Anthocyanin contents for CCA extract, CCG extract, CCU extract and aqueous extract are 265.03 mg/L, 148.24 mg/L, 723.21 mg/L and 220.11 mg/L respectively. In particular, the CCU extract yielded a higher amount of anthocyanin compared to the aqueous extract.

Overall, DES solvents showed similar antioxidant capacity and total phenolic content as aqueous extraction methods, but classic water extraction were more efficient in acquisition of the carbohydrate content. Anthocyanin content was obtained at the highest level in the CCU extract.

Antimicrobial activity of the extracts

Based on antibacterial and antifungal analysis given in Figure 1 and Figure 2; DES extracts of *V. opulus* fruit showed inhibitory effects against the growths of gram positive *Staphylococcus aureus* bacteria, gram negative *Escherichia coli* bacteria and *Candida albicans* fungus whereas the aqueous extract showed none.

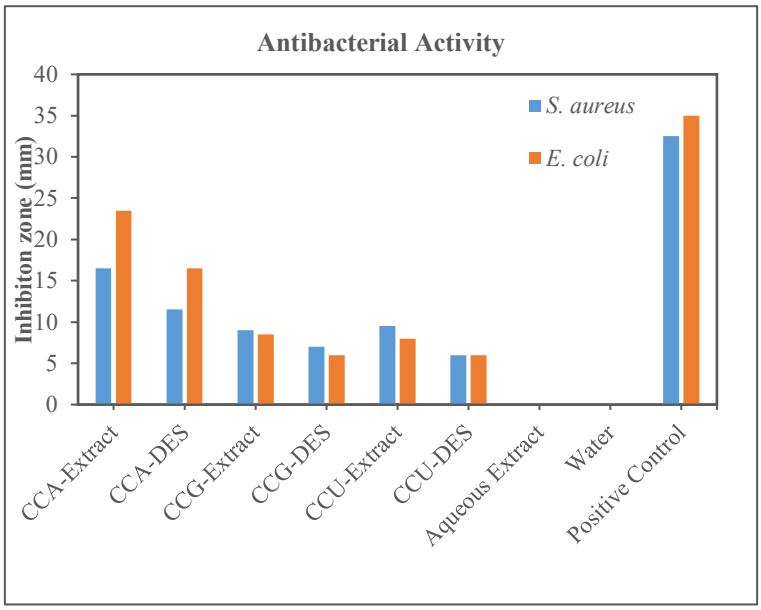

Figure 1. Antibacterial effect of Gilaburu-DES extracts (● E. coli, ● *S.aureus*)

Antibacterial inhibition zones for *Staphylococcus aureus* bacteria for extracts of CCA, CCG and CCU are 16.5 ± 1.5 mm, 9 ± 0.1 mm and 9.5 ± 0.5 mm respectively. For *Escherichia coli* bacteria, zones for extracts of CCA, CCG and CCU are 23.5 ± 1.5 mm, 8.5 ± 0.5 mm and 8 ± 0.01 mm respectively. No antibacterial activity was observed in aqueous extracts. Positive control inhibition diameters were found to be over 30 mm. From these results it could be assessed that extract's antibacterial activity was higher against gram negative bacteria. In addition, antibacterial activity has been detected in DESs themselves. The antibacterial activities of both DES and plant extract combined have produced positive results. CCA has the highest antibacterial inhibition shown due to acetic acid's inherent antimicrobial activity (Ryssel et al., 2009).

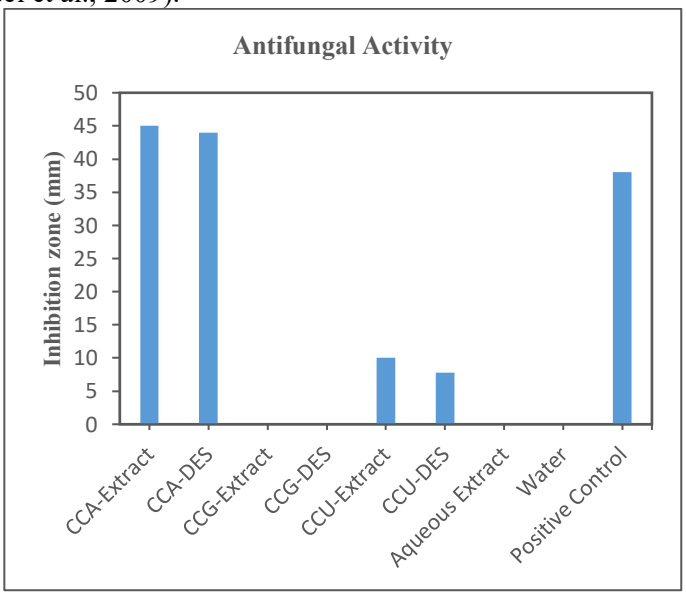

Figure 2. Antifungal effect of Gilaburu-DES extracts

Antifungal inhibitory zone diameters for CCA and CCU extracts are 45 ± 1.2 mm and 10 ± 1.2 mm respectively. No antifungal activity was observed in aqueous and CCG extracts. In addition, antifungal activity has been detected in both CCA-DES and CCU-DES. CCA again showed the highest inhibitory activity due to acetic acid's inherent antimicrobial activity. CCA extract and CCA-DES have surpassed the positive control result (Ryssel et al., 2009).

The determination of antibacterial and antifungal properties of various fruit extracts has attracted great interest in the food and pharmaceutical industries in recent years. Sagdic et al. tested the different concentrations of extracts based on antibacterial effect on different microorganisms using the agar diffusion method. All bacteria were inhibited by 10% and 15% concentrations of this extract (Sagdic et al., 2006). Also, in another study, the antimicrobial activities of *V. opulus* fruit juice and ethanol extracts against human pathogens were compared using the agar well diffusion method. A total of ten Gram-positive and Gram-negative bacterial cultures and nine yeast strains were used in the aforementioned study. The juice showed higher activity compared to the ethanol extracts. The most potent antibacterial activity in the juice was measured against *Salmonella typhimurium, Salmonella agona,* and *Listeria monocytogenes*, with inhibition zones of 27.9, 26.3, and 26.5 mm, respectively. However, yeast growth was affected to a much lesser extent (Česonienė et al., 2014).

Analyzing our results it could be said that with the usage of DES solvents, *V. opulus* showed high antibacterial and antifungal activity. It is recommended that the anticancer, antiviral, and antidiabetic activities of the *V. opulus* plant be studied by extracting it with different DES solutions for future studies.

CONCLUSION

Today, many medicinal plants and their derivatives with high bioactive metabolite contents are being researched due to their potential as antibacterial and antifungal agents. *Viburnum opulus*, also known as the European guelder rose or Gilaburu, exhibits various biological activities and has traditionally been used to provide numerous benefits, particularly for liver and stomach problems. Furthermore, DES have several benefits over traditional solvents like low volatility, low toxicity and high biodegradability. In this study, *V. opulus* fruit was extracted with choline chloride based DES and compared the aqueous extract in terms of total phenolic, carbohydrate and anthocyanin contents, antioxidant and antimicrobial activities. Total carbohydrates were obtained at high levels in the aqueous extract, while total phenolic values and antioxidant activities were obtained in a similar range, and the highest anthocyanin was obtained in the CCU extract. The results are particularly significant in that the antimicrobial activities of DES extracts are higher than those obtained by aqueous extraction, especially for those extracted with CCA.

Abstract

Fish are among the foods included in human diets for maintaining a healthy life, particularly due to their content of polyunsaturated fatty acids. The total lipid level and fatty acid profile in fish tissues are substantially influenced by numerous factors, including the biological characteristics of the species, the ecological conditions of the habitat in which they reside, and seasonal variations.

This study was conducted to determine the seasonal variations in lipid and fatty acid composition of gilthead seabream (*Sparus aurata* L.), a species widely cultured in Türkiye, reared in two distinct marine environments, the Mediterranean and the Aegean Seas. As study material, gilthead seabream (*Sparus aurata*) cultured in marine cages in the Mediterranean (İskenderun) and the Aegean (Muğla) regions were used, and analyses were carried out over a 12-month period to cover all seasons.

Significant differences were observed in lipid content, ΣSFA, and ΣMUFA levels depending on seasonal and regional factors, while the highest lipid content occurred in the summer season. ΣPUFA and Σn-3 fatty acid levels reached their maximum values during the spring period. In addition, the n-3/n-6 ratio was found to fall within the recommended range for human health across both regions and all seasons. The findings obtained in this study demonstrate that cultured gilthead seabream reared in the Aegean and Mediterranean regions is a rich nutritional source of polyunsaturated fatty acids (PUFAs). These results are expected to provide valuable contributions to supporting human health, optimizing nutritional strategies, and establishing a scientific basis for functional food development efforts.

Keywords: Gilthead seabream, *Sparus aurata*, lipids, fatty acids, omega-3.

INTRODUCTION

Fish is considered a valuable component of the human diet due to its nutritional properties. It constitutes a significant source of essential nutrients, including structural and functional lipids that are rich in omega-3 (n-3) fatty acids, several of which play a crucial role in maintaining human health (Carr et al., 2023). Due largely to its content of long-chain polyunsaturated n-3 fatty acids, fish consumption is recommended twice weekly. These fatty acids, which are highly important in human nutrition, have been shown to play roles in numerous metabolic functions (Tilami and Sampels, 2017). Additionally, increasing consumer awareness of the health benefits of fish and the diversity of species available on the market has contributed to a recent rise in global seafood consumption (Costa et al., 2020).

Gilthead seabream is one of the most important marine fish species cultured in Europe, predominantly produced in the Mediterranean and Northern European countries. Türkiye also holds an important position in gilthead seabream production (Metin et al., 2021). In this study, seasonal variations in lipid and fatty acid composition of gilthead seabream cultured under identical feeding conditions in two seas with differing physical and chemical properties, such as temperature, salinity, pH, and density (the Mediterranean and the Aegean), were investigated. To this end, the lipid and fatty acid profiles of gilthead seabream cultured in cages in these two distinct marine environments were analyzed throughout the study period, and differences in lipid composition among the fish were

determined. In light of the findings obtained, the study is expected to provide valuable scientific data to the existing literature regarding the nutritional value of gilthead seabream in terms of polyunsaturated fatty acids (PUFAs) and its potential contribution to human health.

MATERIALS AND METHODS

The gilthead seabream (*Sparus aurata*) used as study material was obtained from a company engaged in marine aquaculture in the Mediterranean (İskenderun) and the Aegean (Muğla) regions. Fish sourced from the two different locations were transported in polystyrene boxes under cold chain conditions, iced with flake ice, using the company's refrigerated vehicles, to the Quality Control Laboratory of the Fisheries Processing Technology Department at Muğla Sıtkı Koçman University Faculty of Fisheries. Lipid and fatty acid composition analyses were performed on all gilthead seabream brought to the laboratory as raw material. The study was conducted over four seasons, namely spring, summer, autumn, and winter.

Lipid Analysis

Lipid content was determined based on the method of Bligh and Dyer (1959). Approximately 5 g of each sample was weighed on a precision balance with 0.1 mg sensitivity (SHIMADZU ATx224, Philippines) and homogenized with 120 mL of a methanol–chloroform mixture in a 1:2 ratio. Subsequently, 20 mL of 0.4% $CaCl_2$ solution was added to the samples, which were then filtered through filter paper (Schleicher & Schuell, 5951/2, 185 mm) into pre-weighed flasks and incubated in an oven at 105ºC for 4 hours. The flasks were sealed to prevent air entry and left overnight in the dark. The following day, the chloroform+lipid-containing lower phase was separated from the methanol+water upper phase using a separating funnel. The chloroform from the remaining solution in the flask was evaporated using a rotary evaporator (HEIDOLPH LABOROTA 4003, Germany) in a 60ºC water bath. Afterwards, the flasks were placed in an oven at 60ºC for 1 hour to ensure complete evaporation of chloroform. Once removed from the oven, the flasks were cooled to room temperature in a desiccator and weighed on a precision balance with 0.1 mg sensitivity. The percentage of crude lipid content was then calculated using the following Eq. (1).

% Crude Lipid = [(Weight of flask + lipid (g) – Weight of empty flask (g)) / Sample weight (g)] x 100 (1)

Fatty Acid Composition Analysis

The fatty acid composition of gilthead seabream samples was determined using gas chromatography with a flame ionization detector (GC-FID). Lipids extracted from the samples using the method of Bligh and Dyer (1959) were methylated by adding 4 mL of 2 N potassium hydroxide, vortexing for 1 minute, and then adding 2 mL of hexane. The mixture was vortexed for another 1 minute and centrifuged at 4°C and 4,000 rpm for 10 minutes. The supernatant was transferred to Eppendorf tubes and, if necessary, diluted with hexane at a 1:3 ratio (Ichihara et al., 1996). Samples were stored at –85°C until injection into the GC system. The methylated fatty acids were analyzed using an Agilent 7820 GC system equipped with an FID detector and an HP-88 capillary column (60 m × 0.25 mm ID × 0.25 µm). The injector and detector temperatures were set at 220°C and 280°C, respectively. The oven temperature was initially held at 140°C for 5 minutes, then increased to 200°C at a rate of 4°C per minute, and finally ramped from 200°C to 220°C at 1°C per minute. A 1 µL sample was injected, with carrier gas pressure maintained at 16 psi. A split ratio of 1:50 was applied. Fatty acids were identified by comparison of their retention times with a 37-component FAME standard mixture (Supelco).

Statistical Analysis

Experiments were performed in triplicate (n = 3) for three independent samples and a completely randomized design was used. Data are presented as mean values plus/minus standard deviations, and a probability value of $P<0.05$ was considered as significant. Analysis of variance was performed, and the mean comparisons were done using Duncan's multiple range tests. Statistical analysis was performed using the IBM SPSS Statistics for Windows, version 21 (IBM Corp., Armonk, NY, USA).

RESULTS AND DISCUSSION

Lipid Analysis Results

The percentage lipid content of gilthead seabream cultured in the Mediterranean (İskenderun) and the Aegean (Muğla) Seas during spring, summer, autumn, and winter is presented in Table 1.

Table 1. Lipid analysis results of gilthead seabream in all seasons (%)

	Spring	Summer	Autumn	Winter
Aegean Gilthead Seabream	9.53 ± 2.70^{aB}	12.10 ± 1.30^{bA}	11.81 ± 0.73^{bA}	12.05 ± 0.75^{aA}
Mediterranean Gilthead Seabream	9.42 ± 0.47^{aC}	14.53 ± 0.07^{aA}	12.67 ± 1.33^{aB}	8.59 ± 0.43^{bD}

Lowercase letters indicate differences between groups within the same season, whereas uppercase letters indicate seasonal differences within the same group ($P<0.05$).

In Aegean gilthead seabream, the highest lipid content was observed in summer at 12.10 ± 1.30%, and the lowest in spring at 9.53 ± 2.70%. In Mediterranean gilthead seabream, the highest lipid content was recorded in summer at 14.53 ± 0.07%, and the lowest in winter at 8.59 ± 0.43% ($P < 0.05$). In a study by Alasalvar et al. (2002), which examined the quality of cultured and wild gilthead seabream stored on ice, the lipid content of cultured seabream was found to be 9.8%. In the present study, lipid content varied seasonally in gilthead seabream reared in both seas. The region appeared to have a significant effect on the lipid content of the fish, particularly during the winter season. The lipid levels in fish flesh may vary depending on several factors, including the capture location, season, and sexual maturity (Babur, 2017).

Fatty Acid Composition Results

The fatty acid composition results of gilthead seabream cultured in the Mediterranean (İskenderun) and the Aegean (Muğla) Seas in all seasons are presented in Table 2.

When the seasonal fatty acid composition of gilthead seabream samples reared in the Mediterranean (İskenderun) and Aegean (Muğla) regions was examined, palmitic acid was found to be the dominant saturated fatty acid in both regions during the spring season. In this season, palmitic acid was measured at 12.05 ± 0.04% in both Mediterranean and Aegean gilthead seabream. Among monounsaturated fatty acids, oleic acid (C18:1 n-9) had the highest proportion in both regions, recorded at 31.54 ± 0.02% in the Mediterranean and 30.67 ± 0.11% in the Aegean. Within the polyunsaturated fatty acids (PUFAs), linoleic acid (C18:2 n-6) was the dominant PUFA in spring, observed at 20.99 ± 0.05% in the Mediterranean and 20.34 ± 0.11% in the Aegean. Regarding n-3 fatty acids, EPA (C20:5 n-3) levels were 2.37 ± 0.01% and 2.40 ± 0.00%, while DHA (C22:6 n-3) levels were 8.60 ± 0.23% and 8.78 ± 0.23% in the Mediterranean and Aegean gilthead seabream, respectively.

A similar fatty acid profile was observed during the summer season, with palmitic acid remaining the dominant SFA in both regions (Mediterranean: 12.14 ± 0.50%; Aegean: 12.01 ± 0.22%). Within the MUFA group, oleic acid continued to be the predominant component, measured at 34.99 ± 0.03% in Mediterranean gilthead seabream and 34.26 ± 0.10% in Aegean gilthead seabream. In the PUFA fraction, linoleic acid remained dominant during summer, with levels of 20.74 ± 0.20% in the Mediterranean and 22.23 ± 0.16% in the Aegean. EPA levels were 1.81 ± 0.02% and 1.77 ± 0.03%, while DHA levels were 6.65 ± 0.13% and 6.30 ± 0.08% in Mediterranean and Aegean samples, respectively. The total PUFA (ΣPUFA) content during summer was calculated as 31.24 ± 0.35% in Mediterranean gilthead seabream and 32.67 ± 0.18% in Aegean gilthead seabream.

Lowercase letters indicate differences between groups within the same season, while uppercase letters indicate seasonal differences within the same group ($P<0.05$).

When the fatty acid profile during the autumn season was examined, palmitic acid was observed to be the dominant saturated fatty acid in both Mediterranean and Aegean gilthead seabream, with values of 9.46 ± 0.28% and 11.55 ± 0.04%, respectively. Among monounsaturated fatty acids, oleic acid (C18:1 n-9) remained the predominant MUFA in both regions, measured at 39.01 ± 0.16% in the Mediterranean and 35.02 ± 0.06% in the Aegean. In the polyunsaturated fatty acid group, linoleic acid (C18:2 n-6) was again the most abundant component, with levels of 21.47 ± 0.13% in the Mediterranean and 22.13 ± 0.08% in the Aegean. During the same season, EPA (C20:5 n-3) contents were 1.79 ± 0.01% and 1.58 ± 0.00%, while DHA (C22:6 n-3) levels were 7.45 ± 0.06% and 6.33 ± 0.06% in Mediterranean and Aegean gilthead seabream, respectively. Evaluating the total fatty acid classes for the autumn season, Mediterranean gilthead seabream contained ΣSFA 15.00 ± 0.42%, ΣMUFA 46.70 ± 0.29%, and ΣPUFA 33.19 ± 0.23%, whereas in Aegean gilthead seabream, these values were 17.72 ± 0.06%, 42.12 ± 0.07%, and 32.73 ± 0.05%, respectively.

During the winter season, palmitic acid was identified as the dominant SFA in gilthead seabream from both regions, with levels of 12.24 ± 0.01% in the Mediterranean and 14.83 ± 1.66% in the Aegean. Within the MUFA fraction, oleic acid (C18:1 n-9) remained the predominant fatty acid, measured at 37.20 ± 0.11% in Mediterranean gilthead seabream and 36.75 ± 1.00% in Aegean gilthead seabream. In the PUFA group, linoleic acid (C18:2 n-6) was the dominant component, recorded at 21.15 ± 0.23% in the Mediterranean and 20.57 ± 0.46% in the Aegean. EPA (C20:5 n-3) contents were 1.33 ± 0.03% and 1.07 ± 0.04%, while DHA (C22:6 n-3) levels were 5.30 ± 0.03% and 4.45 ± 0.17% in Mediterranean and Aegean gilthead seabream, respectively. Additionally, total n-3 fatty acids were 8.41 ± 0.05% in the Mediterranean and 7.21 ± 0.30% in the Aegean, whereas total n-6 fatty acids were 21.65 ± 0.23% and 21.15 ± 0.44%, respectively.

The fatty acid composition of fish varies depending on several factors, including seasonal conditions, feeding regime, habitat, species, size, sex, and physiological status (Şen and Uçar, 2021). Various studies on different fish species (sea bream, silver carp, common carp, zander, chub mackerel) have reported that fatty acid profiles and lipid contents change in response to seasonal temperature variations (Kalyoncu et al., 2010; Torno et al., 2019; Ferreira et al., 2020; Kheiri et al., 2022). Analysis of the fatty acid profiles of gilthead seabream revealed that total ΣSFA and ΣMUFA levels exhibited greater variability between regions compared to ΣPUFA, while seasonally, ΣMUFA showed pronounced fluctuations. DHA levels in gilthead seabream from both regions were found to be biologically significant. In both regions, the most abundant saturated fatty acid was palmitic acid, the predominant MUFA was oleic acid, and linoleic acid was the dominant fatty acid among PUFAs. ΣPUFA and Σn-3 values were higher in the spring compared to other seasons. Σn-3 levels were similar between both regions. Seasonal analysis of EPA, DHA, ΣPUFA, and Σn-3 revealed statistically significant differences between groups ($P < 0.05$). The n-3/n-6 ratio of gilthead seabream reared in both regions ranged from 0.34 to 0.61 seasonally. In a study by Khonji et al. (2023) on the fatty acids of 17 fish species in Bahrain (including doubleber bream, Spanish mackerel, and dory snapper), the n-3/n-6 ratio ranged from 0.66 to 2.62. Torrissen et al. (2025) reported that the optimal n-3/n-6 ratio for health should be between 1:1 and 1:5 (0.25–1). The ratios obtained in our study fall within this recommended range.

CONCLUSION

The study results indicate that the n-3/n-6 ratio remained within the recommended range for health across both regions and all seasons, demonstrating that gilthead seabream possesses a high-quality lipid profile and can be considered an important source of omega-3 fatty acids for human nutrition. The findings provide valuable information on gilthead seabream—a widely consumed fish both in Turkey and globally—for consumers, dietitians, and medical professionals, contributing to balanced nutrition and health. Moreover, the data are particularly critical for businesses involved in the production and processing of gilthead seabream, as they can utilize this detailed information on the fish's nutritional composition and flesh quality to optimize marketing, production, and processing strategies.

Abstract

Gliomas are known as highly malignant primary brain tumours. Phosphodiesterase, specifically, isoform PDE4 is highly expressed in brain tumours and involved in the progression of many forms of cancer including gliomas, due to its role in regulating intercellular cAMP levels, PDE4B inhibitors have been observed to promote apoptosis in glioblastoma. Micro- RNAs are small noncoding RNA's that are responsible for regulating gene expression post transcriptionally. Overexpression of oncogenic miRNA influences cell cycle regulation and apoptosis. cAMP signalling is known to interact with miRNA regulation, therefore PDE inhibition could modulate expression level of miRNA's involved in glioma pathology. This study investigates the effects of PDE4B inhibition on the expression levels of miRNAs in different glioma cell lines.

Keywords: Glioma, Mirna, Phosphodiesterase, Cyclic Adenosine Monophosphate

INTRODUCTION

Glioblastoma (GBM), first described by Virchow in 1863 and later classified in detail by Bailey and Cushing (1926), remains the most aggressive primary brain tumour, characterized by rapid proliferation, diffuse infiltration, and profound inter- and intra-tumoral heterogeneity (Agnihotri et al., 2012; Qazi et al., 2017). It is categorized as a WHO grade IV astrocytoma and displays hallmark cancer traits including sustained proliferation, metabolic reprogramming, persistent vascularization, and evasion of immune surveillance (Fouad & Aanei, 2017). Clinically, GBM presents with headaches, seizures, cognitive decline, and neurological deficits, with diagnosis confirmed by MRI/CT followed by biopsy (Hansen et al., 2023). Standard therapy surgical resection followed by radiotherapy and temozolomide (TMZ) yields limited survival benefits, further constrained by chemoresistance mechanisms such as MGMT promoter silencing, aberrant DNA repair, and altered signalling pathways (Weller et al., 2005; Hegi et al., 2005; Singh et al., 2020). Molecularly, GBM is driven by alterations in EGFR, PTEN, IDH1, ATRX, and RTK-mediated pathways such as PI3K/AKT/mTOR and MAPK/ERK, which collectively contribute to tumour progression and therapy resistance (Kanderi et al., 2025; Xu et al., 2020).

A growing body of evidence highlights the role of cyclic nucleotide phosphodiesterases (PDEs), particularly the PDE4 family, in GBM biology. PDE4 regulates intracellular cAMP levels, a critical second messenger involved in cell proliferation, apoptosis, and differentiation. GBM cells exhibit reduced cAMP and aberrant PKA/CREB signalling, promoting malignant behaviour (Mucignat-Caretta et al., 2017). PDE4B inhibition through agents such as rolipram or Roflumilast has been shown to elevate cAMP, trigger apoptotic signalling, and suppress tumour growth via pathways including EGR1/PTEN/AKT (Li et al., 2024; Goldhoff et al., 2008). Given the intertwining of cAMP homeostasis with glioma pathogenesis, PDE4B has emerged as a therapeutic target (Sengupta et al., 2011).

MicroRNAs (miRNAs) play essential roles in GBM development, acting either as oncogenes or tumour suppressors. Dysregulation of miRNAs such as miR-21, miR-34a, the miR-221/222 and miR-183-96-182 clusters have been documented to contribute in proliferation, EGFR upregulation, invasion, and chemoresistance (Yin et al., 2012; Chen et al., 2021; Schneider et al., 2022; Ordóñez-Rubiano et al., 2024). Several miRNAs directly modulate key GBM pathways, including PI3K/AKT/mTOR and EGFR/RAS/ERK, linking them to disease progression and therapeutic vulnerability (Sati & Parhar, 2021; Xu et al., 2020).

Importantly, cAMP-regulated signalling interacts with miRNA networks, suggesting that PDE4B inhibition may influence miRNA expression profiles relevant to GBM pathology. This intersection of pathways in PDE4B activity, cAMP dynamics, and oncogenic miRNA regulation, forms the conceptual foundation for investigating PDE4B inhibitors as modulators of miRNA expression in glioma.

MATERIALS AND METHODS

The study was designed to evaluate the effects of PDE4B inhibitors on micro RNA's that are overly expressed/ antiapoptotic in glioblastoma. The chosen miRNA's are predicted to target the PDE4B gene (this prediction was assessed with the use of the search engine miRPathDb 2.0, miRwalk and Tarbase). Four cell lines were used: U87MG, LN-18, YKG-1, and HUVEC (as a non-cancerous control). The chosen miRNA are as follows:

Micro-RNA	Function in glioblastoma	
Hsa-miR-221-3p/ Has-miR-222-3p	Overly expressed /oncogenic in many glioblastoma cell lines, supressing of these miRNA's lead to reduced cell proliferation and the upregulation of their target genes- most notably the P53- induced pro apoptotic protein PUMA.	(Mafi et al., 2022) (Ahir et al., 2017) (Chen et al., 2018) (Zhu et al., 2022) (You, 2009) (Jegathesan et al., 2024)
Hsa-miR-182-5p/Hsa-miR-183-5p	Upregulated/oncogenic in glioblastoma thought to be achieved through suppression of neurofilament light polypeptide, a tumour suppressor, activating mTOR signalling pathway	(Schneider et al., 2022) (Ahir et al., 2017)
Hsa-miR-223-3p	Categorized in many studies as an oncogenic miRNA involved in chemotherapeutic resistance, Via regulation/activation of PI3K/AKT pathway and decreased expression of PAX6	(Han et al., 2019) (Huang et al., 2017) (Jegathesan et al., 2024)

The experimental workflow consisted of two major phases: determining cell viability under different drug concentrations and subsequently analysing miRNA expression following treatment.

The first methodological component involved cell culture, where all cell lines were maintained under standard incubator conditions using appropriate media and supplements. This was followed by the MTT cell viability assay, which was performed after treating the cells with a range of concentrations of both PDE4B inhibitors Roflumilast and Apremilast. The purpose of the assay was to identify the optimal treatment dose for subsequent procedures.

Upon dose determination, the second phase of the study began with total RNA isolation from both treated and untreated cells. RNA quality and quantity were assessed to ensure suitability for downstream applications. The extracted RNA was then used for cDNA synthesis, specifically designed for micro-RNA targets.

Following cDNA generation, quantitative real-time PCR (RT-qPCR) was performed to assess expression levels of five target microRNAs (hsa-miR-221-3p, hsa-miR-222-3p, hsa-miR-223-3p, hsa-miR-182-5p, and hsa-miR-183-5p). U6 snRNA was used as the internal reference gene. Fold-change calculations were used to determine upregulation or downregulation in response to PDE4B inhibitor treatments.

Throughout all experiments, standardized laboratory equipment, chemical reagents, miRNA-specific primers were used.

Finally,all Statistical analysis is carried out using GraphPad Prism version 8.0.2. depending on the experimental design either a one-way ANOVA (for comparisons that require more than 2 groups) followed by post hoc Tukey test, or t-tests (for experimental setups that require 2 groups). IC_{50} values were calculated using the AAT Bioquest® IC_{50} Calculator (online tool)

RESULTS and DISCUSSION

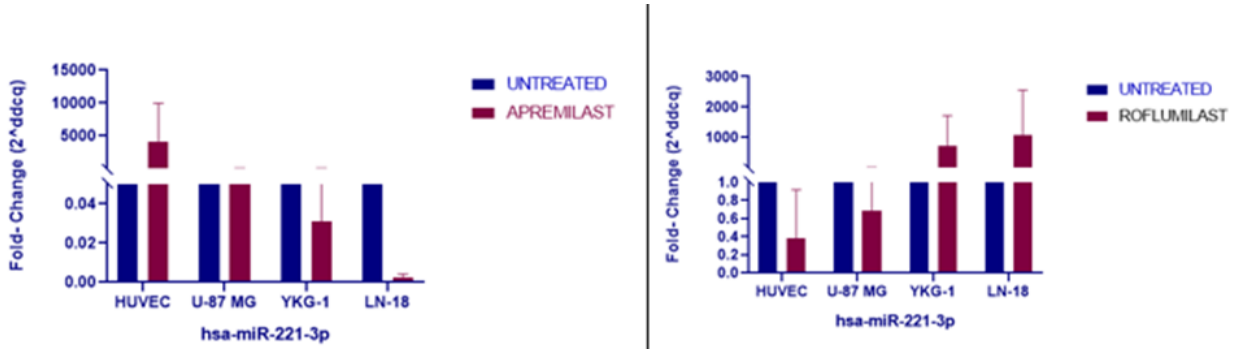

Figure 1. Fold gene expression of hsa-miR-221-3p across all cell lines following 24- hour treatment

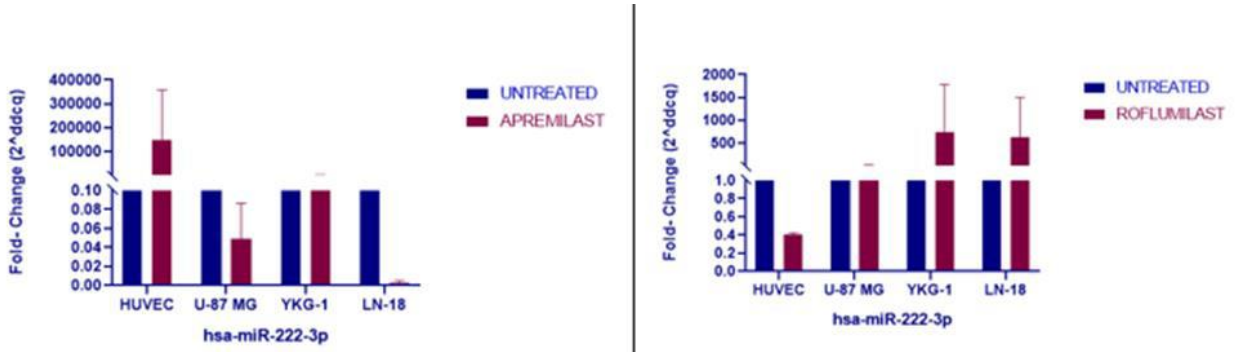

Figure 2. Fold gene expression of hsa-miR-222-3p across all cell lines following 24- hour treatment.

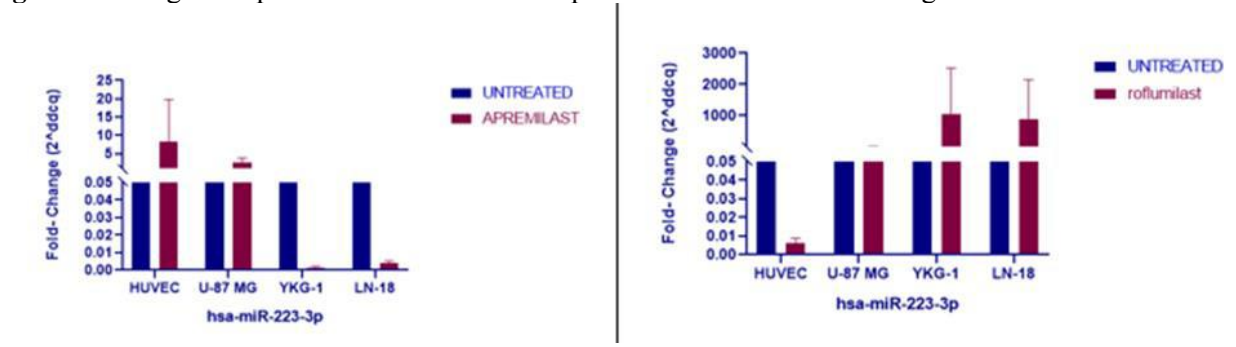

Figure 3. Fold gene expression of hsa-miR-223-3p across all cell lines following 24- hour treatment

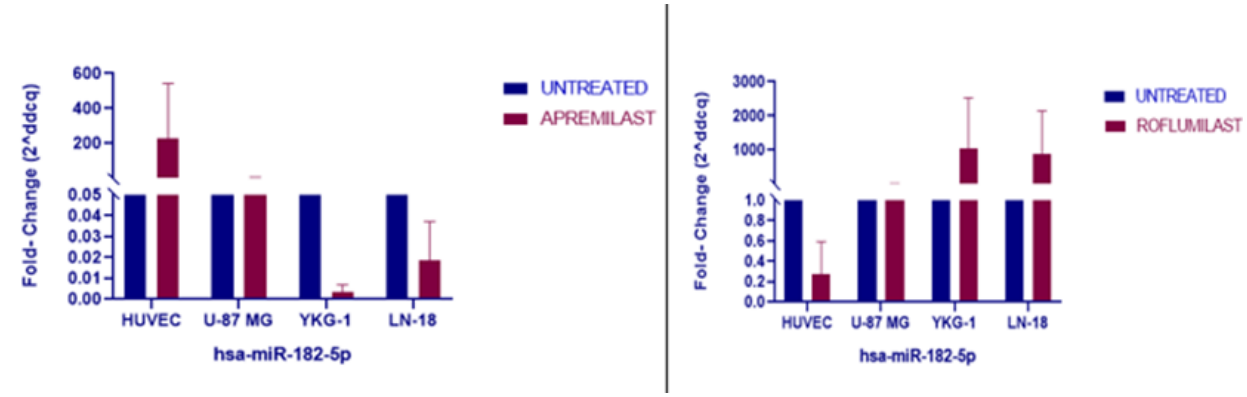

Figure 4. Fold gene expression of hsa-miR-182-5p across all cell lines following 24- hour treatment

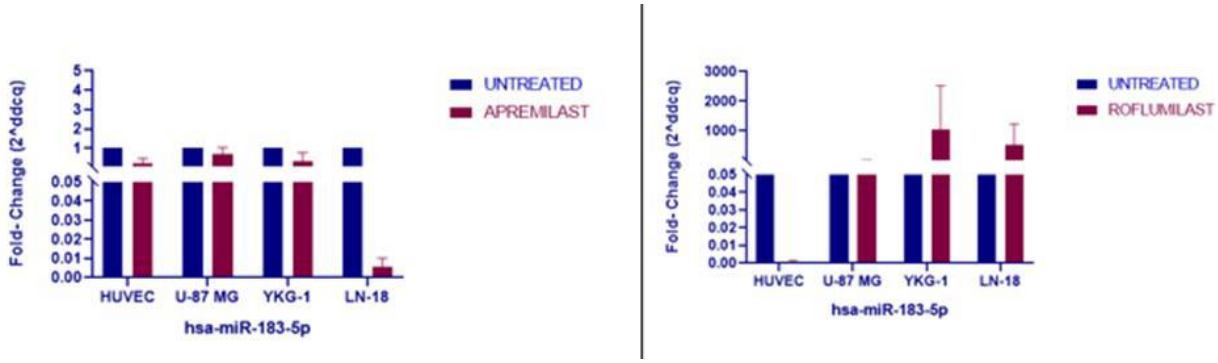

Figure 5. fold gene expression of hsa-miR-183-5p across all cell lines following 24- hour treatment.

This study examined the effects of two PDE4B inhibitors, Apremilast and Roflumilast, on three glioblastoma cell lines (U-87 MG, LN-18, YKG-1) and a control line (HUVEC), focusing on five miRNAs known to be upregulated in glioma. MTT assays across multiple time points showed no meaningful viability differences between 48 and 72 hours, so 24 hours was selected for further analysis. The most cytotoxic dose within the tested range (Table 1), not the calculated IC_{50}, was used for miRNA expression studies. Overall, cell viability did not follow a clear dose-dependent pattern, but both inhibitors produced comparable ranges of viability reduction within each cell line, consistent with previous findings on PDE4 inhibition in glioma.

Table 1. Chosen Dose Per Treatment And Cell Line

Cell line	Apremilast	Roflumilast
HUVEC	4uM	4uM
U- 87 MG	7uM	2uM
LN-18	3uM	4uM
YKG-1	2uM	6uM

RT-qPCR results although showed no statistical significance, demonstrated distinct and opposing reactions to both inhibitors (Figures 1 through 5). In the LN-18 and YKG-1 cell lines, Roflumilast consistently upregulated all five target miRNAs, contradicting past studies associating their downregulation with apoptosis. Apremilast, however, caused a consistent downregulation of the same target miRNAs in the LN-18 and YKG-1 cell lines. The U-87 MG cell line showed a mixed but related pattern, with Roflumilast generally showing higher miRNA expression in comparison to Apremilast. In contrast, HUVEC exhibited an inverted trend, with Apremilast upregulating and Roflumilast downregulating most of the target miRNAs, suggesting tumour-specific regulatory mechanisms.

These findings could suggest that although both drugs elevate intracellular cAMP, their downstream effects differ. Roflumilast, being a more targeted PDE4B inhibitor, may activate pathways such as CREB or ERK, contributing to miRNA upregulation. Apremilast, a broader PDE4 inhibitor, may shift signaling toward PKA-mediated suppression of oncogenic pathways, resulting in miRNA downregulation. Differences between glioma and HUVEC responses further highlight the influence of baseline genetic and signaling contexts. Overall, the results suggest that PDE4B inhibition engages complex, cell-specific pathways that differentially regulate oncogenic miRNAs.

In conclusion, PDE4B inhibitors exert significant therapeutic effects on glioma cell lines, these effects have been correlated with the expression of miRNA's in glioma cell lines although as perviously mentioned, the expression levels have so statistical significant standing, observing a consistent pattern in response to the treatments, can be a basis for further investigation of a regulatory relationship between miRNA expression and the role of the PDE4B gene in glioma, promoting progress towards using miRNA's as a possible biomarker in glioma.

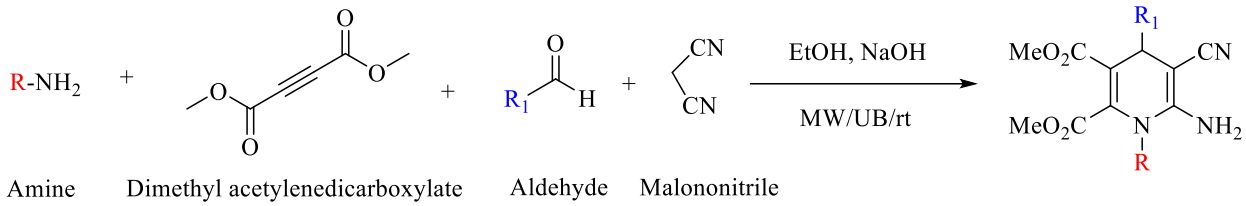
Abstract

In this study, using 4-fluoroaniline as the amine and 3,4-dihydroxybenzaldehyde and phenylacetaldehyde as the aldehydes, new bioactive compounds were synthesized using a multicomponent reaction method in the presence of dimethyl acetylenedicarboxylate and malononitrile. These compounds were characterized and their anticancer activities were investigated using *in silico* and *in vitro* experiments. Using methods known in the literature but modified by us, a combination of bioactive compounds was achieved. Consequently, the original hybrid molecules 1(a-b), which are predicted to have potential drug properties, were synthesized in good yields. Their anticancer potential was investigated using *in silico* and *in vitro* methods. The structures of all synthesized compounds were elucidated using IR, ^{1}H-NMR, ^{13}C-NMR (APT), and TOF-LC/MS spectroscopy. Cell proliferation studies conducted using the XTT method revealed that all synthesized hybrid molecules exhibited dose-dependent antiproliferative activity in the HT-29 colon cancer cell line at concentrations ranging from 0.1 to 25 µM, and IC_{50} values were calculated. Furthermore, all hybrid molecules exhibited antiproliferative activity in the 3T3-L1 healthy cell line at much higher concentrations (10-250 µM). All hybrid molecules demonstrated significantly higher selectivity against cancer cells compared to 5-FU, which is considered a standard chemotherapeutic agent.

Keywords: Anticancer activity, HT-29, *in silico* study, Multicomponent reaction.

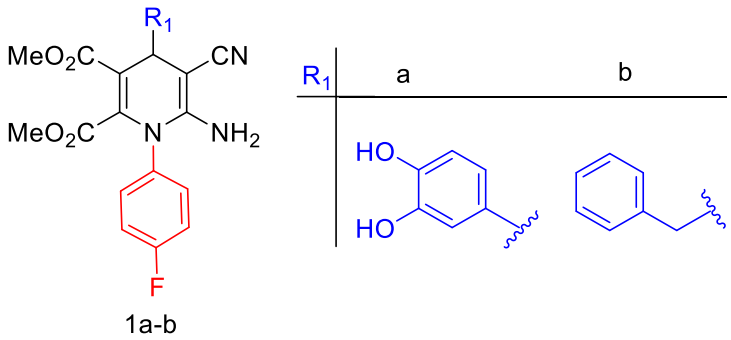
INTRODUCTION

Multicomponent Reactions (MCRs) are convergent reactions, in which three or more starting materials react to form a product, where basically all or most of the atoms contribute to the newly formed product. In an MCR, a product is assembled according to a cascade of elementary chemical reactions. Significant advances have been made in the discovery of drug products using these reactions, which are very useful in the optimization of biologically active compounds (Reddy et al. 2019).



Synthesis of natural product-like molecules by multicomponent reaction

Multicomponent reactions, which are very useful in optimizing biologically active compounds, have led to significant advances in drug discovery (Dömling 2000). Nearly two million natural product-like structures have been produced using MCR methods (Lee et al. 2000). Many biotechnology and major pharmaceutical companies are currently utilizing MCR chemistry to create chemical diversity. Organic chemists are working to improve MCRs by developing new catalysts and reaction conditions (Weber 2002).



On the other hand, cancer treatments need to utilize new approaches that target cancer cells without harming normal cells. Although many anticancer drugs have been developed today, a therapeutic product with the desired therapeutic effect has not yet been developed. Furthermore, due to the development of resistance mechanisms against chemotherapeutic agents for various reasons and their undesirable side effects, their therapeutic power is gradually diminishing. At the same time, cancer cells can acquire the ability to evade physiological suppressors and spread (metastasis) through mutations. Today, due to the low selectivity of drugs used in routine cancer therapies, the side effects they cause with multiple drug use, and the development of resistance, new drug research remains crucial (Khazir et al. 2020).

To this end, these hybrid molecules were first designed and synthesized in the light of *in silico* studies. *in Vitro* studies were conducted on HT-29 colon cancer cell lines to investigate the anticancer effects of these molecules as protein kinase inhibitors.

Based on literature, the four-component one-pot reaction conditions were modified by using temperature, solvent, catalyst, microwave device, and ultrasonic bath (Sun et al. 2010), and the molecules 1(a-b) were synthesized by reacting with appropriate amines and aldehydes in the presence of dimethyl acetylenedicarboxylate and malononitrile (Scheme 1, Scheme 2). The anticancer potential of these molecules was determined by *in silico* studies and *in vitro* experiments.

Scheme 1: General synthesis equation

Scheme 2: General scheme of the synthesized molecules

MATERIALS AND METHODS

General Synthesis Method of Compounds 1(a-b)

As shown in Scheme 2, the corresponding aldehyde (10 mmol) and malononitrile (10 mmol) were slurried in ethanol in the presence of NaOH (10 mmol) for 15 minutes at room temperature (25 °C). Afterward, the corresponding aliphatic/aromatic amine (10 mmol) and dimethyl acetylenedicarboxylate (10 mmol) were added to the reaction medium. The reaction mixture was stirred at room temperature (25 °C) until the reaction was complete (reaction time was determined by Thin Layer Chromatography). At the end of the reaction, the solvent was removed under reduced pressure and the resulting viscous substance was purified using appropriate column chromatography. Reaction conditions were tested using an ultrasonic bath (US) or microwave (MD) device, using triethylamine (TEA) instead of NaOH or Montmorillonite K-10 as a catalyst. The optimal reaction conditions were determined as described above.

The products were purified by column chromatography (silica gel, 30-400 mesh). The column was conditioned with n-hexane. The crude extract was dissolved in ethyl acetate (5 mL) and applied to the column. Purification was carried out using n-hexane-ethylacetate (9:1; 8:2, 7:3; 6:4; 5:5; 4:6; 3:7, 2:8, and 1:9; 100 mL each) solvent systems of increasing polarity.

Dimethyl-6-amino-5-cyano-4-(3,4-dihydroxyphenyl)-1-(4-fluorophenyl)-1,4-dihydropyridine-2,3-dicarboxylate (1a): Verim: % 75 (2.39 g), brown viscous substance. MALDI-TOF-MS: 421.43, 402.16 $[M-1-H_2O]^+$.

in Silico Analyses (Molecular Docking Technique)

in Silico studies of the designed and synthesized molecular systems in this study were conducted using molecular docking analysis. High-resolution crystal structures of the macromolecules 5UBR and 4EKL, which are thought to be effective against HT-29 colon cancer and with which the designed molecules could interact, were obtained from the Protein Data Bank (pdb) website (https://www.rcsb.org/). Molecular docking studies were performed using the AutoDock Vina program (Trott and Olson 2010; Eberhardt et al. 2021). Visualizations of molecular interactions within the macromolecule-ligand complexes obtained from the molecular docking studies were obtained using the DSV program (BIOVA 2020).

2.3. Anticancer Activity Assays

2.3.1. Application of Synthesized Molecules to Cancer and Healthy Cell Lines and Investigation of Their Effects on Cell Proliferation Using the XTT Assay

The XTT [(2,3-bis-(2-methoxy-4-nitro-5-sulfophenyl)-2*H* tetrazolym-5-carboxanilide)] method was used to determine changes in cell proliferation. In this method, cell proliferation is determined by colorimetric measurement of mitochondrial enzyme activity due to the decrease in formazan dyes or XTT. Proliferating cells utilize the XTT salt, and due to increased dehydrogenase activity, the XTT salt is converted into an orange, water-soluble formazan product. The resulting color change is measured using a spectrophotometer or ELISA reader to determine changes in cell proliferation (Nowak et al. 2018). As part of the proposed project, the following were aimed at determining the effects of compounds with effective binding scores to 5UBR and 4EKL and the chemotherapeutic drug 5-FU on the proliferation of a human colon cancer cell line (HT-29) and a healthy cell line (3T3-L1) based on molecular docking analyses:

1. 200 µL (10 x 104 cells/mL) of the counted cells in culture medium were seeded into each well of a 96-well plate and incubated overnight in an incubator at 37°C and 5% CO_2 to allow the cells to adhere to the surface.

2. Following incubation, the medium in the plate was removed, and each well was washed with Dulbecco's phosphate-buffered saline (DPBS) buffer, and the DPBS was removed.

3. Each compound to be tested was prepared in culture medium at different concentrations (0.25, 0.5, 1, 2.5, 5, 10, 25, and 50 µM) from the stock solution. 100 µL was added to a 96-well plate and incubated for 24 and 48 hours at 37°C in a 5% CO_2 incubator. Cells containing only complete medium were used as the control group.

4. After the incubation periods, each well was washed with 100 µL of PBS. 100 µL of fresh complete medium was added to these wells, and 50 µL of the prepared XTT solution (100 µL activator for 5 mL of XTT) was added to each well and incubated for 6 hours in a 5% CO_2 incubator. 5. Cells incubated with XTT solution were measured at 470 nm absorbance using a microplate reader spectrophotometer (Altay et al. 2022).

*Complete medium to be used for the colon cancer cell line (HT-29): 10% fetal bovine serum (FBS) and 1% penicillin/streptomycin (pen/strep) in McCoy's 5A Medium

*Complete medium to be used for the healthy cell line (3T3-L1): 10% FBS and 1% pen/strep in DMEM medium

*Each compound to be tested was dissolved in dimethyl sulfoxide (DMSO) at 1 mg/mL, then vortexed and sonicated at +4°C for 10 minutes to ensure complete dissolution. The resulting stock solution was stored at +4°C until used.

The decrease in cell proliferation was calculated using the following equation: % Proliferation = [Abs (compound-treated cells) – Abs (compound in cell-free medium)] / [Abs (control group cells) – Abs (cell-free medium)] X 100.

Based on the results, the IC_{50} value of each compound was calculated using the statistical program GraphPad Prism Software (GraphPad Software, San Diego, CA). The IC_{50} value is the concentration of the compound required to reduce cell proliferation by 50%.

RESULTS

Synthesis Study

TEA, used in the literature, was insufficient to cause the reaction to proceed as desired. Montmorillonite-K-10, used in the literature, was tested as a catalyst, but no product formation was observed. Therefore, the more basic NaOH was used, and better results were obtained.

Consequently, the corresponding aldehyde compound and malononitrile were first stirred in EtOH in the presence of NaOH for 15 minutes at room temperature. The corresponding amine compound and dimethylacetylenedicarboxylate were then added and stirred at room temperature (25 °C) for 24 hours.

Evaluation of *in Silico* (Molecular Docking Studies) Results

In molecular docking studies, the interactions of designed molecules thought to be effective against colon (HT-29) cancer with the macromolecules 5UBR (Qin et al. 2017) and 4EKL (Lin et al. 2012) were determined, and the results were presented in detail.
Table 1 shows the binding scores for ligand molecules docked into both macromolecules. Figure 1 provides 2D visualizations of the macromolecule-ligand interactions.

Table 1. Best binding scores of the designed molecules in target macromolecules

Comp.	**PDB ID: 5UBR**	**PDB ID: 4EKL**
	Attachment score (kcal/mol)	**Attachment score (kcal/mol)**
1a	-6.90	-7.40
1b	-7.30	**-8.30**
5-Florourasil	-4.50 -5.10	

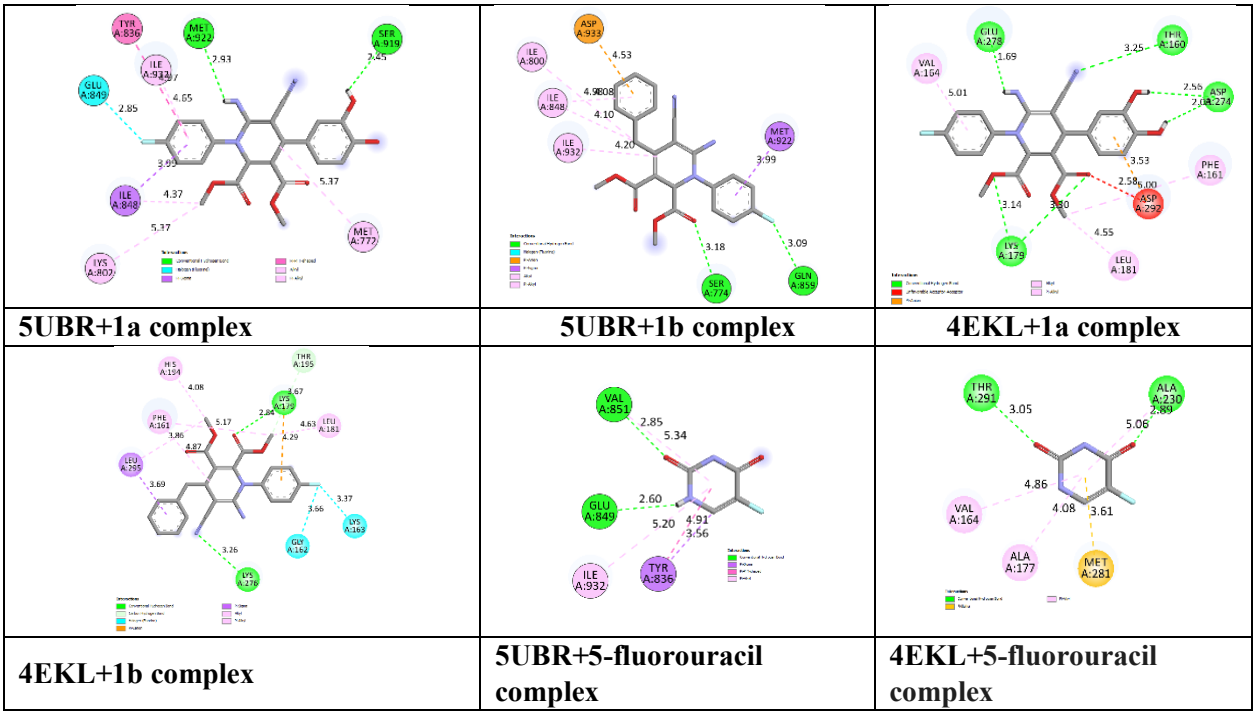

Figure 1. Interaction of molecules 1(a-b) synthesized with 5UBR and 4EKL macromolecules in the HT-29 colon cancer cell line and 5-FU, a standard anticancer drug.

Antiproliferative Effects of the Synthesized Molecules on Colon Cancer (HT-29) and Healthy Cell Lines (3T3-L1)

The dose-dependent antiproliferative effects of the synthesized hybrid molecules 1(a-b) on human colon cancer (HT-29) and mouse embryonic fibroblast (3T3-L1) cell lines were examined using the XTT method. The dose-dependent antiproliferation results of the test samples on the HT-29 cell line are shown in Figure 2. A microscopic image of the antiproliferative effects of 1b, which exhibited the strongest antiproliferative activity among the test compounds, on the HT-29 cancer cell line is shown in Figure 2. The IC_{50} (concentration of the test compound that halves cell viability) values of the test compounds on both cell lines are given in Table 2.

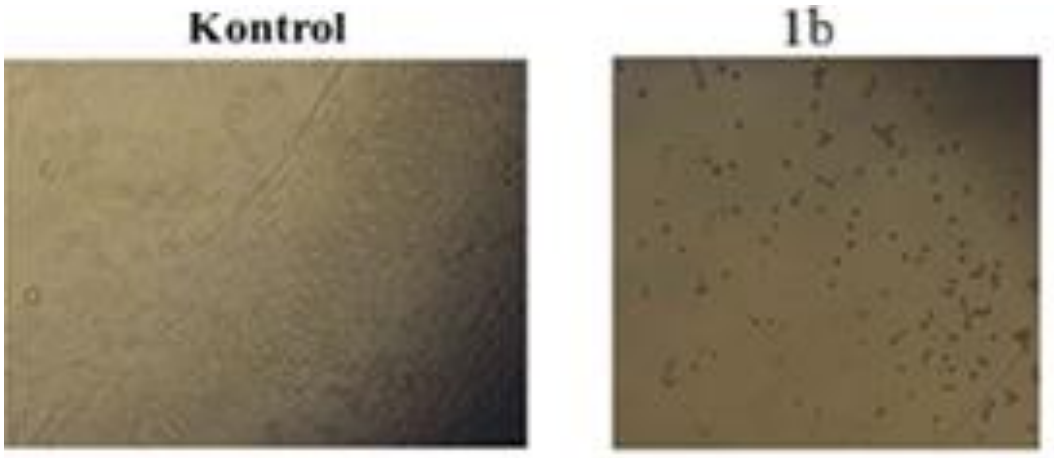

Figure 2. Microscopic image of the antiproliferative effect of the synthesized hybrid molecules 1b on the HT-29 cancer cell line.

Table 2. IC_{50} (µM) values of the synthesized hybrid molecules 1(a-b) and the chemotherapeutic drug 5-FU on HT-29 and 3T3-L1 cell lines

Test comp.	HT-29	3T3-L1
1a	4,29±0,82	142,78±1,35
1b	**0,52±0,06**	97,33±0,92
5-FU	19,84±0,94	46,27±0,88

DISCUSSION

The XTT colorimetric assay is a widely used method for evaluating the antiproliferative potential of natural or synthetic compounds (Roehm et al. 1991). In this study, the dose-dependent antiproliferative effects of the first synthesized hybrid molecules 1(a-b) on human colon cancer (HT-29) and mouse embryonic fibroblast (3T3-L1) cell lines were investigated using the XTT method, and the IC_{50} (the concentration of the test compound that halves cell viability) values of the test samples on HT-29 and 3T3-L1 cell lines were determined. Compounds 1(a-b) were applied to HT-29 cancer cells for 24 hours and all test compounds were found to exhibit dose-dependent antiproliferative activity at varying percentages in the concentration range of 0.1 to 25 µM. Among these compounds, compound 1b showed the strongest antiproliferative effect with the lowest IC_{50} value (0.52 µM), followed by compound 1a (4.29 µM).

When conducting *in vivo* and *in vitro* anticancer activity studies of naturally or synthetically derived compounds, one of the key parameters is the selectivity of the test compounds between cancer and healthy cells. In this context, derivatives 1(a-b), which exhibited strong antiproliferative activity on the HT-29 colon cancer cell line, were also tested on the healthy embryonic fibroblast 3T3-L1 cell line, demonstrating the selectivity of these compounds between healthy and cancer cell lines. When the antiproliferative activities of the test samples against the 3T3-L1 cell line were examined, compound 1b showed the strongest activity with an IC_{50} value of 97.33 µM, while compound 1a had an IC_{50} value of 142.78 µM. The IC_{50} value of the chemotherapeutic drug 5-FU on the same cell line was determined as 46.27 µM. These data indicate that 5-FU is approximately 2.33-fold more selective against HT-29 cells compared to 3T3-L1 cells, while the test compounds exhibited much higher selectivity, ranging from 187- to 613-fold.

When the structure-biological activity relationship is examined, compounds 1(a-b) share a central backbone group and a fluorobenzene attached to it. What distinguishes these compounds is the substituted benzene ring attached to the central backbone, which has a pharmacophore effect. Among these pharmacophore groups, the aromatic benzene ring contributes slightly more to the antiproliferative effects of these compounds compared to other compounds in the literature. The findings obtained from in vitro experimental studies were found to strongly support the in silico study results. Among the test compounds, compound 1b, which had the strongest binding score to the 4EKL protein, was determined to have the strongest antiproliferative effect against HT-29 cells as a result of XTT tests. According to *in silico* molecular docking results, all designed molecules exhibited higher binding scores to 5UBR and 4EKL proteins compared to 5-FU on HT-29 colon cancer.

CONCLUSION

The synthesized 1(a-b) hybrid molecules exhibited dose-dependent antiproliferative effects on HT-29 cancer cell lines. All synthesized molecules were found to have statistically more potent antiproliferative effects than 5-FU, a standard chemotherapeutic agent used in colon cancer cell lines. The synthesized hybrid molecules were observed to have significantly higher IC_{50} values in the 3T3-L1 healthy cell line compared to the HT-29 cancer cell line. This suggests that the synthesized hybrid molecules exhibit higher selectivity for cancer cells compared to healthy cells.

Özet

Dünya Sağlık Örgüt'ünün yaptığı araştırmaya göre küresel nüfusun %80'i sağlık hizmetlerinde 1. basamak olarak bitkisel tedavi yöntemlerini kullanmaktadır. Bunun asıl nedeni insanların doğal antioksidan kaynaklarına karşı olan ilgisi ve güvenidir. Günümüzde teknolojinin ilerlemesiyle birlikte tıp alanında incelemeler artmış ve bitkilerin sahip olduğu etken bileşenler bilimsel çalışmalara konu olmuştur. Böylece bitkiler fitoterapi adı verilen bilim dalı ile desteklenip modern tıbbın tamamlayıcısı olarak kabul görmüştür. Özellikle Güneydoğu Anadolu bölgesinde kullanımı oldukça yaygın olan yarpuz bitkisini yöre halkı; yeni doğum yapmış kadınlara rahimin rahatlaması amacıyla ve soğuk algınlığı, grip, baş ağrısı, solunum yolu enfeksiyonları gibi rahatsızlıkların tedavisinde bu bitkiden faydalanmıştır. Bu rahatsızlıklardan müzdarip kişiler yarpuz bitkisinin yapraklarının kurtulmasıyla elde edilen çayı tüketerek tedavi edilmiştir. Literatürde bu konu ile ilgili yapılan çalışmalar incelendiğinde; yarpuz bitkisinin antioksidan içeriğinin oldukça zengin olduğu ve bu bitkinin biyoaktif bileşenlerinin de aktif olduğu sonucuna varılmıştır. Sonuç olarak *Mentha pulegium* bitkisinin yüksek antioksidan kapasitesi ve geniş etki spektrumu ve modern fitoterapötik uygulamalarda değerlendirilmesi, bitkinin hem bilimsel hem de uygulamalı araştırmalarda geniş bir kullanım potansiyeline sahip olduğunu göstermektedir.

Anahtar Kelimeler: Yarpuz otu, Fitoterapi, Antioksidan, Antimikrobiyal

Health Effects of Phenolic Compounds from *Mentha pulegium*

Abstract

According to research conducted by the World Health Organization, 80% of the global population uses herbal remedies as a primary healthcare option. This is primarily due to people's interest in and trust in natural antioxidant sources. With technological advancements, medical research has increased, and the active components of plants have become the subject of scientific studies. Thus, plants have been supported by the scientific field of phytotherapy and are now accepted as complementary to modern medicine. The *Mentha pulegium* plant we feature in this project belongs to the Lamiaceae family. The plant, particularly used in Southeastern Anatolia, is widely used by local people. It has been used by women who have recently given birth to relax the uterus and to treat ailments such as colds, flu, headaches, and respiratory infections. Those suffering from these ailments have been treated with a tea made from dried leaves of the plant. When looking at the studies on this subject in the literature, When the study was examined, it was concluded that the antioxidant content of pennyroyal is very rich and the bioactive components of this plant are also active.In conclusion, the high antioxidant capacity and broad spectrum of action of *Mentha pulegium*, and its evaluation in modern phytotherapeutic applications, indicate that the plant has a wide potential for use in both scientific and applied research.

1.GİRİŞ

Tarih öncesi dönemlerden itibaren insanlar bitkilerin tedavi edici gücünü keşfedip ondan yararlanmıştır. Literatürde araştırdığımız zaman yazılı kaynaklardan bunun antik döneme kadar dayandığını görmekteyiz. Günümüzde ise modern teknolojik yaklaşımlar sonucu tıp alanındaki araştırmalar artmış ve bitkilerin sahip olduğu fenolik bileşenleri, antioksidan, antimikrobiyal özellikleri, etki mekanizmaları gibi pek çok etken incelenerek bilimsel çalışmalara konu olmuştur. Böylece bitkiler fitoterapi adı verilen bir bilim dalı ile desteklenmiş ve modern tıbbın tamamlayıcıları olarak kabul görmüşlerdir. Dünya Sağlık Örgütü'ne göre, dünya nüfusunun yaklaşık %80'i temel sağlık hizmetlerinde bitkisel ilaçlardan faydalanmaktadır (WHO, 2013). Bu oranın yüksek olmasının nedeni ise bu yöntemin doğal tedavi yöntemlerine dayanması ve ucuz olmasıdır. Türkiye, farklı iklimlerin görüldüğü geniş coğrafyası ve zengin bitki örtüsü sayesinde çok sayıda tıbbi ve aromatik bitkiye ev sahipliği yapan önemli bir merkezdir (Faydaoğlu ve Sürücüoğlu, 2011). Bu bitkiler arasında *Mentha pulegium* (yarpuz) özellikle Anadolu da geleneksel şifa yöntemi olarak yaygın şekilde kullanılmıştır. Sulak alanların kenarında görülen bitki, haziran ve eylül ayları arasında çiçek açmaktadır ve bitkiyi deniz seviyesinden 1300 metreye kadar olan rakımlarda gözlemlemek mümkündür (Doğan, 2025). "*Mentha pulegium* dünya üzerinde tropikal bölgelerin haricinde hemen her yerde yetişmektedir" (Tanker ve Sezik, 1965). Bu bitkiye ülkemizde özellikle Mardin, Diyarbakır, Adıyaman, Antalya illerinde yaygın bir şekilde rastlarız. Yarpuz otu halk arasında özellikle; minör solunum yolu enfeksiyonları, grip, gut, hepatit, kramp ve daha saymadığımız birçok rahatsızlığın tedavisinde kullanılmıştır ayrıca Yarpuz otu terletici, sakinleştirici, uyarıcı ve tonik bir etkiye sahiptir (Doğan, 2025). Sonuç olarak literatür incelendiğinde, *Mentha pulegium*'un yüksek antioksidan kapasitesi ve geniş etki spektrumu, bitkinin modern fitoterapötik uygulamalarda değerlendirilmesi, bitkinin hem bilimsel hem de uygulamalı araştırmalarda geniş bir kullanım potansiyeline sahip olduğunu göstermektedir.

2.BİTKİNİN BOTANİK ÖZELLİKLERİ

Lamiaceae familyasında yer alan *Mentha pulegium* keskin kokulu ve çok yıllıklı bir bitki olup Türkiye'de Mardin, Diyarbakır, Tekirdağ, Aydın ve daha sayamadığımız bir çok ilde yetişmektedir (Çöteli vd., 2013). Halk arasında bu bitki yarpuz, pung, filiskin olarak bilinmektedir. Genellikle boyu 10 ile 40 cm arasında yapraklar ise 8 ile 30 mm uzunluğunda ve 4 ila 12 mm genişliğinde ve hafif tüylüdür (Doğan, 2025). Çiçekleri mor veya pembe tonlarında olup başak şeklindedir.

Şekil 1. Yarpuz (*Mentha pulegium*) bitkisi (pixabay, t.y.)

3.FITOKIMYASAL BILEŞENLER

Yarpuz otunu incelediğimizde en belirgin özelliği uçucu yağ içeriğinin zengin olmasıdır. Pulegon, piperiton, menthol, menthon gibi bileşikler bu uçucu yağın ana bileşiklerini oluşturmaktadır (Karaman vd., 2021). Farklı coğrafi bölgelerde incelen *Mentha pulegium*'ların bileşik oranlarında farklılık olduğu gözlemlenmiştir. Bunun asıl nedeni iklim, toprak yapısı gibi etmenlerin bu sonucu etkilemesidir. Bitkilerin savunma amaçlı olarak ürettikleri bu bileşikler yabancı ot çimlenmesini de önlemektedir. Biber üzerinden yürütülen bir çalışmada, istenmeyen yabancı otların filizlenmesini engellemek için yarpuz uçucu yağı düşük konsantrasyon da kullanılmış ve çimlenmeyi engellediği görülmüştür. Bu sonuçlar eşliğinde araştırmacılar yarpuz uçucu yağının ara tarım ürünü olarak kullanılabileceği kanısındadır (Karaman vd., 2021).

4.FARMAKOLOJİK ETKİLER

4.1. Antioksidan, Antimikrobiyal ve Anti-inflamatuar Etkiler

Mentha pulegium L. türü Fas'ın geleneksel içeceklerinde aroma verici olarak, yaprakları çiğnenerek hıçkırık tedavisinde, grip, migren, ateş, obezite, kabızlık ve öksürük gibi birçok hastalığı tedavi etmek amacıyla kullanılmıştır (Amtaghri vd., 2024). Bu bitkinin düşük dozda da olsa toksik etkilerine rastlanmıştır. Gelecekte bu bitkinin dağılımına, kimyasal bileşenine ve biyolojik aktivitlerine odaklanıp kapsamlı çalışmalar yapılmalıdır (Amtaghri vd., 2024).

Türkiye'de tıbbi amaçlı olarak tahmini 500 bitki bulunmaktadır bunların yaklaşık olarak 200'ü ihraç potansiyeli yüksek olan bitkilerdir ve bu bitkiler ülke ekonomisine katkı sağlamaktadır (Faydaoğlu ve Sürücüoğlu, 2011). Bu nedenle geleneksel bitkilerin araştırılmasına eğilim artmalıdır çünkü farmasötik amaçlı kullanılan bitkilerin ülke ekonomisine katkı sağlaması öngörülmektedir.

Başka bir çalışmada ise Yarpuz otunun; yapraklarında A vitaminin 0,38±0,08 µg/g, E vitamini miktarının (12,46±1,82 µg/g), β-karoten miktarının 1,24±0,14 µg/g, ve B1, B2, B3, B6 ve B9 vitaminlerinin ise sırası ile 0,50±0,09 µg/g; 43,11±7,02 µg/g; 16,91±1,59 µg/g; 81,88±9,47 µg/g ve 1,53±0,16 µg/g olduğu belirlendi (Çöteli vd., 2013). Bu çalışmayı incelediğimizde de sonuç olarak *Mentha pulegium* B2, B6 vitaminleri ve serbest radikal temizleme etkisi ile antioksidan kapasite bakımından zengin olduğu (Çöteli vd., 2013) görülmektedir ve araştırmacılar bu bitkinin biyoaktif bileşenlerinin araştırmalara daha fazla konu olacağı kanısındadır.

İncelediğimiz çalışmalarda *Mentha pulegum*'un belirgin şekilde antioksidan, antimikrobiyal ve antiinflamatuar özelliklere sahip olduğu görülmektedir. Bitkinin fenolik bileşikleri ve uçucu yağ içerikleri; pulegon ve menthonlar serbest radikallerin temizlenmesine katkı sağlayarak antioksidan etki oluşturmaktadır. Çeşitli mantar, *S. aureus, S. pyogenes, E. Coli* gibi gram pozitif ve gram negatif bakterilere karşıda antimikrobiyal aktivite gösterir. Bitkinin uçucu yağlarının ilthaplanmayı baskılaması da antiinflamatuar etki olduğunu gösterir.

4.2. Toksikolojik Bulgular

Toksikolojik çalışmalar, *Mentha pulegium* bitkisinin düşük dozlarda özütlerinin toksik olmadığını fakat yarpuz uçucu yağının oldukça tehlikeli olduğunu göstermektedir (Amtaghri vd., 2024).

5.SONUÇ

Araştırmalar sonucunda yarpuz bitkisinin etkileri değerlendirilmiş ve incelenen bulgular eşliğinde bu bitkinin antibakteriyal, antioksidan ve antiinflamatuar özelliklere sahip olduğu görülmüştür. Farmakolojik etkisi sayesinde modern ve geleneksel tıpta kullanımı bilimsel olarak desteklenmektedir. Bunun yanında toksikolojik etkilerine karşın net veriler bulunmamaktadır bu nedenle toksikolojik etkilerinin genişletilmesine ihtiyaç vardır. Son olarak yarpuz otunun halk sağlığına olumlu etkilerinin olduğu belirtilen hastalıkların tedavisinde kullanılabileceği ve bitkinin gelecekte tıbbi ve farmasötik alanlarda kullanım potansiyelinin olduğu görülmüştür.

Özet

Nanopartikül sentezinde kullanılan geleneksel fiziksel ve kimyasal yöntemler, genellikle yüksek enerji tüketimi, toksik kimyasalların kullanımı ve tehlikeli yan ürünlerin oluşumu gibi dezavantajlara sahiptir. Bu nedenle, son yıllarda çevre dostu, sürdürülebilir ve ekonomik olan yeşil sentez (green synthesis) yaklaşımları büyük ilgi görmektedir. Yeşil sentez, bakteri, mantar, alg ve özellikle bitki ekstraktları gibi biyolojik kaynakları kullanarak nanopartikül üretimini hedefler. Bitki ekstraktları, içerdikleri flavonoidler, terpenoidler, polifenoller gibi zengin biyoaktif bileşikler sayesinde metal iyonlarını indirgeme ve oluşan nanopartikülleri stabilize etme görevini aynı anda üstlenmektedir. Bu yöntem, toksik olmayan çözücüler (genellikle su) kullanması, oda sıcaklığında veya düşük sıcaklıklarda gerçekleştirilebilmesi ve karmaşık ekipman gerektirmemesi gibi avantajlar sunar. Boraginaceae familyasına ait olan Onosma cinsi, dünya genelinde yayılış gösteren ve geleneksel tıpta yüzyıllardır kullanılan bitkileri içerir. Özellikle yara iyileştirici, antimikrobiyal, antiinflamatuar ve antioksidan özellikleri ile bilinen Onosma türleri, shikonin ve türevleri gibi değerli naftokinon bileşiklerini barındırır. Türkiye florasında da çok sayıda endemik türü bulunan bu cinsin biyoaktif potansiyeli, onu nanopartikül sentezi için değerli bir doğal kaynak haline getirmektedir

Anahtar Kelimeler: onosma, antimikrobiyal, nanopartikül.

Investigation of antimicrobial properties of nanoparticles synthesized from Onosma Alborsea extract

Abstract

Conventional physical and chemical methods used in nanoparticle synthesis often have disadvantages such as high energy consumption, use of toxic chemicals, and formation of hazardous by-products. For this reason, green synthesis approaches that are environmentally friendly, sustainable and economical have attracted great attention in recent years. Green synthesis aims at nanoparticle production using biological sources such as bacteria, fungi, algae and especially plant extracts. Plant extracts simultaneously undertake the task of reducing metal ions and stabilizing the formed nanoparticles thanks to the rich bioactive compounds they contain, such as flavonoids, terpenoids and polyphenols. This method offers the advantages of using non-toxic solvents (usually water), being able to be performed at room or low temperatures, and not requiring complex equipment. The Onosma genus, belonging to the Boraginaceae family, includes plants that are widespread throughout the world and have been used in traditional medicine for centuries. Onosma species, especially known for their wound healing, antimicrobial, anti-inflammatory and antioxidant properties, contain valuable naphthoquinone compounds such as shikonin and its derivatives. The bioactive potential of this genus, which has many endemic species in the Turkish flora, makes it a valuable natural resource for nanoparticle synthesis.

Keywords: onosma, antimicrobial, nanoparticle.

GİRİŞ

Artan antibiyotik direnci, 21. yüzyılın en ciddi halk sağlığı tehditlerinden biri olarak kabul edilmektedir. Geleneksel antibiyotiklerin etkinliğinin azalması, enfeksiyon hastalıklarının tedavisini zorlaştırmakta ve bilim dünyasını acil olarak yeni antimikrobiyal stratejiler geliştirmeye yöneltmektedir. Antimikrobiyal direnç, küresel bir sağlık sorunu olarak giderek daha fazla önem kazanmakta ve yeni, etkili antimikrobiyal ajanların geliştirilmesini zorunlu kılmaktadır. Bu arayışta, nanoteknoloji, materyallere nano boyutlarda kazandırdığı benzersiz fizikokimyasal özellikler sayesinde devrim niteliğinde çözümler sunmaktadır. Özellikle metal ve metal oksit nanopartiküller (NPs), geniş spektrumlu antimikrobiyal aktiviteleri ile dikkat çekmektedir (WHO, 2021). Bu bağlamda, nanoteknoloji ve özellikle bitki bazlı (yeşil sentez) nanopartikül üretimi, umut verici bir yaklaşım olarak öne çıkmaktadır.

Nanopartiküllerin sentezlenmesinde kullanılan kimyasal ve fiziksel yöntemler, genellikle yüksek maliyetli, toksik kimyasallar gerektiren ve çevreye zararlı atıklar üreten süreçlerdir. Bu dezavantajları ortadan kaldırmak amacıyla geliştirilen yeşil sentez (green synthesis) yaklaşımı, bitkiler, algler, mantarlar ve bakteriler gibi biyolojik kaynakları kullanarak çevre dostu, sürdürülebilir ve düşük maliyetli bir alternatif sunmaktadır. **Yeşil sentez**, geleneksel yöntemlerin yüksek enerji tüketimi, toksik kimyasalların kullanımı ve tehlikeli yan ürünlerin oluşumu gibi dezavantajlarını ortadan kaldıran, çevre dostu, sürdürülebilir ve ekonomik bir yaklaşımdır. Bitki ekstreleri, içerdikleri zengin biyoaktif bileşikler (fenolikler, flavonoidler, terpenoidler, alkaloidler ve naftokinonlar) sayesinde metal iyonlarını indirgeyici (reducing agent) ve oluşan nanopartikülleri stabilize edici (capping/stabilizing agent) olarak görev yaparlar (Roy ve ark., 2019).

Boraginaceae familyası, dünya genelinde yayılış gösteren ve yaklaşık 150 cins ile 2500'den fazla türü barındıran, fitokimyasal açıdan zengin bir bitki ailesidir. Bu familyaya ait türler, geleneksel tıpta yüzyıllardır yara iyileştirici, anti-inflamatuar ve antimikrobiyal özellikleri nedeniyle kullanılmaktadır. Özellikle Onosma cinsi, köklerinde bulunan ve güçlü biyolojik aktivitelere sahip olan naftokinon türevleri (shikonin, alkannin ve bunların esterleri) ile tanınmaktadır (Jabbar ve ark., 2022). Bu bileşiklerin güçlü indirgeme potansiyeli, Onosma türlerini nanopartikül yeşil sentezi için ideal bir aday haline getirmektedir.

MATERYAL VE METOT

Bu derleme, Boraginaceae familyasının bir üyesi olan Onosma alborosea'nın nanopartikül özelliklerini inceleyen bilimsel literatürün sistematik bir analizine dayanmaktadır. Literatür taraması, Web of Science, Scopus, PubMed, Google Scholar gibi uluslararası bilimsel veritabanları platformlarda gerçekleştirilmiştir. Tarama sürecinde "Boraginaceae", "Onosma", "nanoparticle", "green synthesis", "antimicrobial gibi anahtar kelimeler ve bunların kombinasyonları kullanılmıştır. Seçim kriterleri, çalışmaların güncelliği, doğrudan onosma ve nanopartikül sentezi ile ilişkili olması ve biyolojik aktivite verilerini içermesi üzerine odaklanmıştır.

BULGULAR ve TARTIŞMA

Boraginaceae (Hodangiller) familyası, çoğunlukla otsu bitkiler olmakla birlikte çalı ve ağaç formlarını da içeren kozmopolit bir ailedir. Genellikle sert tüylerle kaplı yaprak ve gövdeleri ile karakterizedirler. Geleneksel olarak birçok kültürde tıbbi amaçlarla kullanılan bu familya, anti-inflamatuar, yara iyileştirici, antioksidan ve antimikrobiyal potansiyele sahip zengin bir fitokimyasal çeşitlilik sunar (Hosseinpour, 2025). Türkiye florasında Onosma'ya ait 102 bitki türü bulunmakta olup, bu türlerin yaklaşık %50'si endemiktir (Binzet, 2016).

Onosma cinsi, Boraginaceae familyasının en önemli cinslerinden biridir ve dünya genelinde yaklaşık 230 tür ile temsil edilir. Bu türler, özellikle Akdeniz havzası, Orta Doğu ve Asya'da yaygındır. Etnobotanik açıdan, Onosma türlerinin kökleri, "havaciva" olarak bilinir ve geleneksel olarak doğal gıda ve tekstil boyası olarak kullanılmasının yanı sıra, yanık, yara, egzama gibi cilt rahatsızlıklarının tedavisinde ve antimikrobiyal ajan olarak da değerlendirilmiştir (Jabbar ve ark., 2022). Literatür kayıtlarına göre, Onosma türlerinin bronşit, boğaz ağrısı, lökoderma, karın ağrısı ve ateş gibi çeşitli rahatsızlıkların tedavisinde sıklıkla kullanıldığı bilinmektedir (Mašković ve ark., 2015).

Onosma alborosea ekstreleri üzerine yapılan çalışmalar, bitkinin önemli miktarda fenolik bileşik içerdiğini göstermiştir. Erim ve Savcı (2024) tarafından yapılan bir çalışmada, bitkinin metanol ve su ekstrelerinin toplam

fenolik madde içeriği incelenmiş ve antioksidan aktiviteleri değerlendirilmiştir (Erim ve Savcı, 2024). Her ne kadar bu çalışmada antioksidan aktivitenin standartlara göre düşük olduğu belirtilse de, fenolik bileşiklerin (örneğin, ferulik asit, vanilik asit, rosmarinik asit) varlığı, metal iyonlarının indirgenmesi için gerekli elektronları sağlayarak nanopartikül sentezinde rol oynayabileceklerini göstermektedir. Diğer Onosma türleri üzerinde yapılan çalışmalarda, örneğin Onosma frutescens ve Onosma sericea özütlerinin fenolik ve flavonoidler açısından zengin olduğu ve rosmarinik asit, apigenin 7-glukozit, luteolin 7-glukozit, hesperidin, hiperozit, ferulik asit, vanilik asit, kafeik asit ve 4-hidroksibenzoik asit gibi bileşikleri yüksek miktarda içerdiği belirlenmiştir (Sarikurkcu ve ark.,2020).

Onosma cinsinin en karakteristik kimyasal bileşenleri, köklerde biriken kırmızı renkli naftokinon pigmentleridir. Shikonin, alkannin ve bunların çeşitli ester türevleri, bu grubun en bilinen üyeleridir. Naftokinonların yapısındaki kinon halkası, kolayca redoks reaksiyonlarına girme yeteneğine sahiptir. Bu özellik, metal iyonlarını (örneğin Ag^{+}) metalik forma (Ag^{0}) indirgemek için mükemmel bir kimyasal potansiyel sunar ve bu da onları nanopartikül yeşil sentezi için birincil aday haline getirir (Ramos-Peralta ve ark., 2015).

Gündoğan (2021) tarafından yapılan bir tez çalışmasında, Onosma sericeum Willd. bitkisinin kök ekstresi kullanılarak gümüş nanopartiküller (AgNPs) yeşil sentez yöntemiyle elde edilmiş ve bu nanopartiküller içeren yara kremi formülasyonları geliştirilmiştir (Gündoğan, 2021). Bu çalışma, Onosma türlerinin nanopartikül sentezindeki potansiyelini deneysel olarak kanıtlayan önemli bir örnektir. Ayrıca, Onosma bourgaei ekstresi kullanılarak da AgNPs biyosentezi gerçekleştirilmiş ve antimikrobiyal aktivitesi incelenmiştir (Erenler ve Geçer, 2024).

Boraginaceae ekstrelerinden sentezlenen nanopartiküller, özellikle AgNPs, geniş bir patojen yelpazesine karşı güçlü antimikrobiyal aktivite göstermektedir. Etki mekanizmaları tam olarak aydınlatılamamış olsa da, birkaç olası mekanizma öne sürülmektedir: (i) nanopartiküllerin bakteri hücre duvarına ve zarına bağlanarak yapısal bütünlüğünü bozması, (ii) hücre içine girerek DNA ve proteinler gibi hayati makromoleküllerle etkileşime girmesi ve fonksiyonlarını engellemesi, (iii) reaktif oksijen türleri (ROS) üreterek oksidatif strese neden olması (Singh ve ark., 2017). Naftokinonlar gibi biyoaktif moleküllerin nanopartikül yüzeyinde bulunması, bu antimikrobiyal etkiyi sinerjistik olarak artırabilir (Krychowiak ve ar., 2018). Onosma nana etanol ekstrelerinin, S. epidermidis ve P. vulgaris'e karşı kayda değer antimikrobiyal aktiviteye sahip olduğu rapor edilmiştir (Özcan ve Acet, 2024).

SONUÇ

Sonuç olarak, Boraginaceae familyası, zengin ve çeşitli fitokimyasal içeriği sayesinde, çevre dostu, düşük maliyetli ve etkili nanopartiküllerin yeşil sentezi için muazzam bir potansiyel sunmaktadır. Özellikle Onosma cinsi, içerdiği naftokinon türevleri ile bu potansiyeli bir adım öteye taşımaktadır. Bu nedenle, Onosma alborosea türünün, antimikrobiyal özelliklere sahip nanopartiküllerin sentezi için umut verici ve henüz keşfedilmemiş bir kaynak olduğu sonucuna varılmıştır.

ORAL PRESENTATION

Pandemi dönemi ile birlikte beslenme ve sağlık dersinin yeniden yapılandırılması: İçerik, pedagoji ve dijital dönüşüm açılarından nitel bir analiz

Hüseyin Hakan İnce (Orcid: 0000-0001-9873-5731)

Dicle Üniversitesi, Ziya Gökalp Eğitim Fakültesi, Matematik ve Fen Alanlar Eğitimi Bölümü, Diyarbakır, Türkiye

Sorumlu yazar e-mail: hhakanince@hotmail.com

Özet

COVID-19 pandemisi, yükseköğretimdeki tüm dersleri etkilemekle birlikte, sağlık ve beslenme ile ilişkili derslerde çok daha köklü ve hızlı bir dönüşümü zorunlu kılmıştır. Bu çalışma, üniversite düzeyinde verilen *Beslenme ve Sağlık* dersinin pandemi sürecinde nasıl yeniden yapılandırıldığını incelemek amacıyla **nitel doküman analizi** yaklaşımını kullanmaktadır. Veri kaynağı olarak; Dünya Sağlık Örgütü'nün (DSÖ) COVID-19 dönemine yönelik beslenme rehberleri (WHO, 2020), UNESCO ve UNICEF'in post-COVID eğitim raporları (UNESCO, 2020; UNICEF, 2023), beslenme–bağışıklık ilişkisini ele alan güncel derleme makaleleri (Calder, 2020, 2021; Carr & Rowe, 2020; Sadeghsoltani ve ark., 2022; Govers ve ark., 2022) ve çevrim içi öğrenme ile acil uzaktan öğretim arasındaki farkları tartışan eğitim çalışmaları (Hodges ve ark., 2020; Garrison & Kanuka, 2004) kullanılmıştır. Üç aşamalı tematik analiz sonucunda üç ana tema ortaya çıkmıştır: (1) Ders içeriğinin bilimsel olarak güncellenmesi, özellikle bağışıklık fizyolojisi ve mikro besin–immünite ilişkilerinin derinleştirilmesi; (2) öğrenci merkezli pedagojik yaklaşımların güçlenmesi, problem temelli öğrenme, yanlış bilgi vakalarının analizi ve infografik temelli görevlerin yaygınlaşması; (3) dijital öğrenme araçlarının kalıcılaşması, mikro ders videoları, çevrim içi öğrenme yönetim sistemleri ve resmî sağlık otoritelerinin dijital kaynaklarının dersin ayrılmaz parçası hâline gelmesi. Bulgular, pandemiye bağlı düzenlemelerin geçici çözümler değil, dersin bilimsel, pedagojik ve teknolojik altyapısını güçlendiren yapısal iyileştirmeler olduğunu göstermektedir. Sonuç bölümünde, beslenme ve sağlık eğitimine yönelik sürdürülebilir bir "içerik–pedagoji–teknoloji üçgeni" modeli önerilmekte ve gelecekteki olası salgınlar için ders tasarımına yönelik öneriler sunulmaktadır.

Anahtar Kelimeler: Beslenme eğitimi, bağışıklık sistemi, COVID-19, mikro besinler, yanlış bilgi, dijital öğrenme, nitel doküman analizi.

Reconstruction of the Nutrition and Health Course with the Onset of the Pandemic Period: A Qualitative Document Analysis on Content, Pedagogy, and Digital Transformation

Abstract

The COVID-19 pandemic has impacted all areas of higher education; however, it has necessitated a far more profound and rapid transformation in courses related to health and nutrition. This study employs a qualitative document analysis approach to examine how the university-level *Nutrition and Health* course was restructured during the pandemic period. The data sources include the World Health Organization's (WHO) nutrition guidelines for the COVID-19 era (WHO, 2020), UNESCO and UNICEF post-COVID education reports (UNESCO, 2020; UNICEF, 2023), recent review articles addressing the relationship between nutrition and immunity (Calder, 2020, 2021; Carr & Rowe, 2020; Sadeghsoltani et al., 2022; Govers et al., 2022), and educational studies discussing the distinctions between online learning and emergency remote teaching (Hodges et al., 2020; Garrison & Kanuka, 2004).

A three-stage thematic analysis revealed three major themes: (1) scientific updating of course content, particularly the deepening of topics related to immune physiology and micronutrient–immunity interactions; (2) the strengthening of learner-centered pedagogical approaches, including problem-based learning, the analysis of misinformation cases, and the integration of infographic-based tasks; and (3) the institutionalization

of digital learning tools, such as micro-lecture videos, online learning management systems, and digital resources from official health authorities. The findings indicate that the modifications made during the pandemic are not temporary solutions but rather structural improvements that reinforce the scientific, pedagogical, and technological foundations of the course. The conclusion section proposes a sustainable "content–pedagogy–technology triangle" model for nutrition and health education and offers recommendations for course design in preparation for potential future pandemics.

Keywords: Nutrition education, immune system, COVID-19, micronutrients, misinformation, digital learning, qualitative document analysis.

GİRİŞ

COVID-19 pandemisi, küresel ölçekte yükseköğretimi hem organizasyonel hem de pedagojik açıdan zorlayan, aynı zamanda dönüştüren bir süreç olmuştur. UNESCO'nun "Education in a post-COVID world: Nine ideas for public action" raporunda, pandeminin eğitim sistemlerinin kırılganlıklarını açığa çıkarmakla kalmayıp, daha kapsayıcı ve esnek yapılar için bir fırsat penceresi de oluşturduğu vurgulanmaktadır (UNESCO, 2020). Bu bağlamda *Beslenme ve Sağlık* dersinin içerik ve pedagojik yönlerden yeniden ele alınması kaçınılmaz hâle gelmiştir.

Pandemi sürecinde beslenme–bağışıklık ilişkisine yönelik bilimsel araştırmalar hız kazanmış; özellikle mikro besinlerin immün fonksiyonlardaki rolü daha görünür hâle gelmiştir (Calder, 2020, 2021; Govers ve ark., 2022). Bağışıklık sisteminin vitamin A, C, D, E ile çinko, demir, selenyum gibi eser elementlerden doğrudan etkilendiği ve bu besin öğelerinin enfeksiyon riskini düşürmede önemli olduğu ortaya konmuştur (Calder, 2020, 2021). C vitamininin solunum yolu enfeksiyonlarında oksidatif stresin azaltılması ve nötrofil fonksiyonlarının düzenlenmesindeki rolü çeşitli derlemelerde ayrıntılandırılmıştır (Carr & Rowe, 2020; Cerullo ve ark., 2020). Çinkonun antiviral yanıt ve solunum yolu enfeksiyonları üzerindeki etkileri de güncel derlemelerde kapsamlı şekilde ele alınmaktadır (Sadeghsoltani ve ark., 2022).

Diğer yandan, sosyal medya ortamında beslenme ile ilgili yanlış bilgilerin hızla yayılması, "infodemi" kavramı ile açıklanmaktadır (Cinelli ve ark., 2020). Bu durum, ders kapsamında **yanlış bilgi okuryazarlığının** ele alınmasını zorunlu hâle getirmiştir.

Pedagojik açıdan bakıldığında, üniversitelerin hızla çevrim içi eğitime geçmesi, literatürde "acil uzaktan öğretim" olarak tanımlanmış ve bu modelin, planlı ve pedagojik olarak tasarlanmış bir çevrim içi eğitimden önemli ölçüde farklı olduğu vurgulanmıştır (Hodges ve ark., 2020). Buna karşın harmanlanmış (blended) öğrenme yaklaşımının, yüz yüze ve çevrim içi bileşenleri bütünleştirerek yükseköğretimde dönüştürücü bir potansiyel taşıdığı ifade edilmektedir (Garrison & Kanuka, 2004).

Bu nedenle çalışmanın temel araştırma sorusu şu şekilde formüle edilmiştir:

Pandemi sürecinde üniversite düzeyinde yürütülen Beslenme ve Sağlık dersi, içerik, pedagojik yaklaşım ve dijital öğrenme araçları açısından nasıl yeniden yapılandırılmıştır?

MATERYAL VE METOT

Araştırma Deseni

Çalışmada, metin temelli kaynakların sistematik ve eleştirel analizine odaklanan **nitel doküman analizi** deseni kullanılmıştır. Bu yaklaşım, bir dersin yeniden yapılandırılma sürecini resmî raporlar, rehber dokümanlar ve bilimsel yayınlar üzerinden ortaya koymak için uygundur.

Veri Kaynakları

Analize dâhil edilen dokümanlar dört ana grupta toplanmıştır:

Uluslararası sağlık otoriteleri

DSÖ'nün COVID-19 ve beslenme ile ilgili çevrim içi rehberleri ve bilgi notları (WHO, 2020).

Eğitim politikası ve dönüşüm raporları

UNESCO'nun pandemiden sonra eğitim sistemlerini yeniden düşünmeye yönelik raporu (UNESCO, 2020).

UNICEF destekli "Education in a post-COVID world: Towards a RAPID Transformation" raporu (UNICEF, 2023).

Beslenme–bağışıklık ilişkisine odaklanan bilimsel derlemeler

Beslenme, bağışıklık ve COVID-19'a ilişkin derlemeler (Calder, 2020, 2021).

C vitamininin solunum yolu enfeksiyonlarındaki rolü (Carr & Rowe, 2020; Cerullo ve ark., 2020).

Çinko ve antiviral immün yanıt üzerine güncel derlemeler (Sadeghsoltani ve ark., 2022; Govers ve ark., 2022).

Çevrim içi öğrenme ve acil uzaktan öğretim literatürü

Acil uzaktan öğretim–planlı çevrim içi öğrenme ayrımı (Hodges ve ark., 2020).

Harmanlanmış öğrenmenin yükseköğretimdeki potansiyelini tartışan çalışmalar (Garrison & Kanuka, 2004).

Ayrıca COVID-19 bağlamında yanlış bilgiye ilişkin infodemi çalışmaları da yanlış bilgi boyutunun tartışılması için kullanılmıştır (Cinelli ve ark., 2020).

Veri Analizi

Dokümanlar, üç aşamalı bir tematik analiz sürecine tabi tutulmuştur:

Açık Kodlama: Beslenme–bağışıklık, gıda güvenliği, yanlış bilgi, dijital öğrenme ve öğretim stratejileri ile ilgili anlamlı ifadeler kodlanmıştır.

Eksen Kodlama: Benzer kodlar bir araya getirilerek daha üst düzey kategoriler oluşturulmuştur (örneğin "mikro besin–immünite", "yanlış bilgi okuryazarlığı", "acil uzaktan öğretimden planlı çevrim içi öğrenmeye geçiş").

Seçici Kodlama: Bu kategoriler, dersin yeniden yapılandırılmasını açıklayan üç ana tema altında bütünleştirilmiştir: bilimsel içerik modernizasyonu, öğrenci merkezli pedagojik dönüşüm ve dijital öğrenme ekosistemlerinin kalıcılaşması.

Çalışma yalnızca kamuya açık dokümanları analiz ettiğinden, etik kurul izni gerekmemiştir.

BULGULAR

Tematik analiz sonucunda üç ana tema ve bunları destekleyen çok sayıda alt tema belirlenmiştir.

Bilimsel İçerik Modernizasyonu

Pandemi sonrası *Beslenme ve Sağlık* dersinin içeriğinde en belirgin değişim, bağışıklık fizyolojisi ve mikro besin–immünite ilişkilerine ayrılan yerin artmasıdır. Beslenme ve bağışıklık ilişkisini ele alan derlemelerde, yaşlanma, obezite, mikro besin eksiklikleri ve bağırsak mikrobiyotası gibi faktörlerin immün sistem üzerindeki etkileri ayrıntılı biçimde sunulmuştur (Calder, 2020, 2021; Govers ve ark., 2022).

Ders kapsamında artık yalnızca "C vitamini bağışıklığı güçlendirir" gibi düz cümleler yerine:

C vitamininin nötrofil fonksiyonu, oksidatif stres ve solunum yolu enfeksiyonlarıyla ilişkisi (Carr & Rowe, 2020; Cerullo ve ark., 2020),

Çinkonun antiviral immün yanıt ve solunum yolu enfeksiyonları bağlamındaki etkileri (Sadeghsoltani ve ark., 2022; Govers ve ark., 2022),

Çoklu mikro besin eksikliklerinin immün yanıtı nasıl zayıflattığı

gibi mekanizma odaklı içeriklere yer verilmektedir.

DSÖ'nün beslenme tavsiyeleri de ders materyallerine doğrudan entegre edilmiştir; böylece öğrenciler hem akademik çalışmaları hem de küresel sağlık otoritelerinin rehberlerini birlikte yorumlayabilmektedir (WHO, 2020).

Öğrenci Merkezli Pedagojik Dönüşüm

İkinci ana tema, dersin öğrenen merkezli yöntemlerle zenginleştirilmesidir. Problem temelli öğrenme (PBL) senaryoları ve vaka analizleri aracılığıyla öğrenciler, pandemi dönemine özgü karmaşık problemlere çözüm üretmektedir. Örneğin:

Gelir düzeyi kısıtlı bir ailenin, DSÖ'nün önerdiği dengeli beslenme ilkelerine mümkün olduğunca yaklaşmasını sağlayacak haftalık menü tasarlanması,

Sosyal medyada sık dolaşan "tek bir besinle bağışıklığı mucizevi biçimde güçlendirme" iddialarının bilimsel açıdan eleştirel incelenmesi,

Çinko ve C vitamini içeren takviye reklamlarının klinik kanıtlar ışığında değerlendirilmesi.

Bu süreç, öğrencilerin hem bilimsel muhakeme hem de yanlış bilgiye karşı direnç geliştirmelerini desteklemektedir. COVID-19'a ilişkin infodemi çalışmalarında yanlış bilginin dijital ağlarda salgın benzeri dinamiklerle yayıldığının gösterilmesi, bu tür pedagojik uygulamaların önemini artırmaktadır (Cinelli ve ark., 2020).

Ayrıca öğrencilerden, mikro besin–immünite ilişkilerini ve gıda güvenliği ilkelerini açıklayan infografikler hazırlamaları istenmekte; bu da soyut biyolojik mekanizmaları görselleştirerek öğrenmeyi kolaylaştırmaktadır.

Dijital Öğrenme Ekosistemlerinin Kalıcılaşması

Üçüncü tema, pandeminin başında zorunlulukla devreye giren dijital araçların, zaman içinde dersin kalıcı ve planlı bileşenleri hâline gelmesidir. Çevrim içi öğretimin kriz dönemindeki kullanımına ilişkin eleştiriler, acil uzaktan öğretim ile planlı çevrim içi öğrenme arasındaki farkın altını çizmektedir (Hodges ve ark., 2020). Bu fark gözetilerek, dersin dijital boyutu yeniden tasarlanmıştır.

Bu çerçevede: bağışıklık ve beslenme konularını işleyen **mikro ders videoları** hazırlanmış,

ders içeriği ve ölçme-değerlendirme süreçleri bir **öğrenme yönetim sistemi** üzerinden yürütülmeye başlanmış,

DSÖ ve UNESCO gibi kurumların çevrim içi kaynaklarına doğrudan bağlantılar verilmiş (WHO, 2020; UNESCO, 2020; UNICEF, 2023),

öğrencilerin yansıtıcı günlükler, forum tartışmaları ve çevrim içi quizler yoluyla etkin katılımı teşvik edilmiştir.

Bu yapı, dersin hem yüz yüze hem de çevrim içi yürütülebilmesine imkân tanıyan hibrit bir esneklik sağlamaktadır. Harmanlanmış öğrenmenin yükseköğretimde derin öğrenmeyi destekleyebileceğine ilişkin bulgular, bu tasarımın kuramsal temelini güçlendirmektedir (Garrison & Kanuka, 2004).

4. TARTIŞMA

Bulgular, *Beslenme ve Sağlık* dersinin COVID-19 sürecinde yalnızca "uzaktan verilmeye başlanmış" bir ders olmadığını; aksine bilimsel içerik, pedagojik yaklaşım ve teknolojik altyapı bakımından yeniden inşa edildiğini göstermektedir.

Bilimsel Derinlik ve Güncellik

Beslenme–bağışıklık literatüründe elde edilen bulgular, dersin kuramsal içeriğinin güncellenmesine güçlü bir temel sağlamıştır (Calder, 2020, 2021; Carr & Rowe, 2020; Sadeghsoltani ve ark., 2022; Govers ve ark., 2022). Bu sayede öğrenciler, vitamin ve mineral önerilerini ezberlemek yerine, bu besin öğelerinin bağışıklık hücreleri, sitokinler ve inflamasyon üzerindeki etkilerini öğrenmektedir. C vitamini ve çinko örnekleri, solunum yolu enfeksiyonları bağlamında özellikle öğretici birer vaka niteliği taşımaktadır.

Bu durum, dersi pandemi sonrasına da taşınabilecek şekilde güncel ve esnek kılmakta; yalnızca SARS-CoV-2 değil, diğer enfeksiyonlar ve kronik hastalıklar bağlamında da değerlendirilebilir bir bilgi zemini oluşturmaktadır.

Eleştirel Düşünme ve Yanlış Bilgiye Karşı Dayanıklılık

COVID-19 infodemisi, bilginin dijital ortamlarda nasıl yayıldığına dair daha derin bir analiz gerektirmiştir. Sosyal medya platformlarında yanlış bilginin yayılımını inceleyen çalışmalar, beslenme ve sağlık eğitiminde yanlış bilgi okuryazarlığının ayrı bir öğretim hedefi olarak ele alınması gerektiğini göstermektedir (Cinelli ve ark., 2020).

Bu çalışmanın bulguları, ders kapsamında problem temelli öğrenme ve vaka analizlerinin kullanılmasıyla öğrencilerin:

bilgi kaynağının güvenilirliğini sorgulama,

kanıt düzeylerini (gözlem, deney, sistematik derleme vb.) ayırt etme,

sosyal medyada karşılaştıkları beslenme iddialarını bilimsel ölçütlerle değerlendirme

becerilerini geliştirdiklerini göstermektedir. Bu kazanımlar, yalnızca akademik başarıyı değil, öğrencilerin bireysel ve toplumsal sağlık kararlarını da doğrudan etkileme potansiyeline sahiptir.

Dijital Dönüşümün Yapısal İyileştirme Olarak Konumlanması

Acil uzaktan öğretim sürecinde dijital araçlar çoğu zaman kısa vadeli çözümler olarak kullanılmıştır (Hodges ve ark., 2020). Ancak elde edilen bulgular, *Beslenme ve Sağlık* dersinde dijital bileşenlerin pandemi sonrasında da sürdürülebilecek biçimde yeniden tasarlandığını göstermektedir. Kısa videolar, resmî kurumların dijital kaynakları ve öğrenme yönetim sistemlerinin birlikte kullanılması, dersin gelecekteki olası krizlere karşı daha dayanıklı hâle gelmesini sağlamaktadır.

UNESCO ve UNICEF'in post-COVID eğitim raporlarında vurgulanan "eşitlik, erişilebilirlik ve dayanıklılık" ilkeleri, bu dönüşümü değerlendirmek için önemli bir çerçeve sunmaktadır (UNESCO, 2020; UNICEF, 2023). Özellikle çevrim içi içeriklerin asenkron biçimde erişilebilir olması, farklı sosyoekonomik ve coğrafi koşullara sahip öğrenciler için fırsat eşitliği açısından önem taşımaktadır.

İçerik–Pedagoji–Teknoloji Üçgeni

Bulgular bütüncül olarak ele alındığında, dersin dönüşümünü açıklamak için içerik–pedagoji–teknoloji üçgenine dayalı bir model önerilebilir:

İçerik: Güncel beslenme–bağışıklık literatürü ve resmî sağlık rehberleriyle güçlendirilmiş ders içeriği,

Pedagoji: Öğrenci merkezli, problem temelli, vaka analizi odaklı yöntemler,

Teknoloji: Hibrit öğrenmeyi destekleyen, planlı biçimde entegre edilmiş dijital araçlar.

Bu üç unsur birlikte ele alındığında, ders yalnızca pandemi döneminin "kriz ürünü" olmaktan çıkmakta; uzun vadeli, sürdürülebilir bir eğitim modeline dönüşmektedir.

SONUÇ VE ÖNERİLER

Bu nitel doküman analizi, *Beslenme ve Sağlık* dersinin COVID-19 pandemisi sürecinde üç temel boyutta yeniden yapılandırıldığını ortaya koymaktadır:

Bilimsel içerik güncellenmiş ve derinleşmiştir. Mikro besin–immünite ilişkileri, bağışıklık fizyolojisi ve gıda güvenliği gibi konular, hem literatür hem de resmî rehberler temel alınarak dersin merkezine yerleştirilmiştir (Calder, 2020, 2021; Carr & Rowe, 2020; Sadeghsoltani ve ark., 2022; WHO, 2020).

Pedagojik yaklaşım öğrenci merkezli hâle gelmiştir. Problem temelli öğrenme, vaka analizi, infografik hazırlama ve yansıtıcı yazma gibi etkinlikler aracılığıyla öğrencilerin eleştirel düşünme ve yanlış bilgiye karşı direnç becerileri güçlenmiştir (Cinelli ve ark., 2020).

Dijital öğrenme araçları kalıcı bir bileşen olarak kurumsallaşmıştır. Mikro ders videoları, öğrenme yönetim sistemleri ve resmî dijital kaynakların entegrasyonu, hibrit ve esnek bir öğrenme ortamı sunmuştur (Hodges ve ark., 2020; Garrison & Kanuka, 2004; UNESCO, 2020; UNICEF, 2023).

Uygulayıcılara Yönelik Öneriler

Ders içerikleri, beslenme–bağışıklık literatüründeki gelişmeler doğrultusunda düzenli aralıklarla güncellenmelidir.

Bilimsel kanıt türleri, yanlış bilgi ve medya okuryazarlığı, dersin açık biçimde belirtilmiş öğrenme çıktıları arasına dâhil edilmelidir.

Çevrim içi bileşenler, yalnızca kriz dönemlerinde değil, yüz yüze eğitimi tamamlayan planlı birer araç olarak tasarlanmalıdır.

Öğrencilerin kendi beslenme davranışlarını yansıtıcı günlükler, beslenme takip formları veya dijital uygulamalar aracılığıyla analiz etmeleri teşvik edilmelidir.

Gelecek Çalışmalar İçin Öneriler

Bu çalışma doküman analizi ile sınırlıdır. Gelecekte:

Öğrenci görüşlerinin,

Öğretim elemanlarının deneyimlerinin ve

Ölçme-değerlendirme sonuçlarının

nitel veya karma yöntemlerle incelenmesi, dersin pandemi sonrası etkilerinin daha kapsamlı değerlendirilmesine katkı sağlayacaktır.

Abstract

Hexavalent chromium (Cr(VI)) is a highly toxic and mobile pollutant in aquatic environments, necessitating efficient removal methods. This study investigates the adsorption performance of modified natural zeolites for Cr(VI) removal from aqueous solutions. Raw zeolite (RZ) was modified using various salts ($CaCl_2$, $MgCl_2 \cdot 6H_2O$, NH_4Cl) and a cationic surfactant, cetyltrimethylammonium bromide (CTAB). Batch adsorption experiments revealed that the surfactant-modified zeolite (SMZ) exhibited the highest Cr(VI) removal efficiency of 29.69%, significantly outperforming the raw and salt-modified zeolites, due to the formation of a positively charged surface that enhances electrostatic attraction. Consequently, SMZ was selected for further parametric studies. The optimal conditions for Cr(VI) adsorption on SMZ were determined as a contact time of 120 minutes, an adsorbent dosage of 10 g/L, and an initial solution pH of 5. Under these optimal conditions, a maximum removal efficiency of 96.01% was achieved for an initial Cr(VI) concentration of 25 mg/L. The results demonstrate that surfactant modification is a highly effective method for enhancing the anion adsorption capacity of natural zeolites, making SMZ a promising and efficient adsorbent for the remediation of Cr(VI)-contaminated wastewater.

Keywords: Hexavalent chromium, Adsorption, Surfactant-modified zeolite, Water treatment.

INTRODUCTION

Hexavalent chromium (Cr(VI)) is a highly toxic and carcinogenic pollutant frequently released from electroplating, leather tanning, textile dyeing, and pigment manufacturing processes. Due to its high solubility and mobility in aqueous environments, Cr(VI) poses a serious threat to both ecosystems and human health, leading to severe biological accumulation, genetic mutations, and organ damage. The World Health Organization (WHO) limits total chromium in drinking water to 0.05 mg/L, highlighting the need for effective removal methods (Saha et al., 2011; Sharma et al., 2022).

Various techniques such as chemical precipitation, ion exchange, and membrane filtration have been employed for Cr(VI) removal; however, adsorption remains the most efficient and economical method (Hailu et al., 2017; Ren et al., 2016; Song et al., 2015). Zeolites, due to their large surface area and ion-exchange properties, are promising adsorbents. Yet, natural zeolites show limited affinity for anionic species like chromate and dichromate ions, necessitating surface modification (Sharma et al., 2022; Shi et al., 2018; Song et al., 2015). Surface modification using surfactants or metal oxides enhances the anion-exchange capacity of zeolites, thereby enabling efficient Cr(VI) adsorption (Hailu et al., 2017; Lv et al., 2014; Song et al., 2015).

This study aims to evaluate the efficiency of modified zeolites in removing Cr(VI) from aqueous solutions and to examine the effects of modification type, contact time, adsorbent dosage, and pH on removal performance.

MATERIALS AND METHODS

Natural zeolite was obtained from a local supplier and used as the base adsorbent. The modification of the raw zeolite (RZ) sample was carried out using chemical methods involving various salts and a cationic surfactant after physical pretreatment with sieving and washing processes. In this context, calcium chloride ($CaCl_2$), magnesium chloride hexahydrate ($MgCl_2 \cdot 6H_2O$), and ammonium chloride (NH_4Cl) salts, as well as the cationic surfactant cetyltrimethylammonium bromide (CTAB, $C_{19}H_{42}NBr$), were used. Distilled water and analytical grade chemicals, including potassium dichromate ($K_2Cr_2O_7$) as the Cr(VI) source and hydrochloric acid (HCl) and sodium hydroxide (NaOH) for pH adjustment, were used throughout the experiments.

In the salt modification, 10 g of the pretreated sample was added to 100 mL of a 2 M solution of the respective salt and stirred at 200 rpm for 12 hours. The obtained modified zeolites were separated from the solution by filtration, thoroughly washed with distilled water, and dried at 105 °C for 12 hours (Huang et al., 2014; Zhan et al., 2017). The zeolites modified with $CaCl_2$, $MgCl_2 \cdot 6H_2O$, and NH_4Cl were designated as CMZ, MMZ, and NMZ, respectively. On the other hand, for the surfactant modification, 10 g of the pretreated zeolite was placed into a 0.05 M CTAB solution (50 mL) and agitated in a thermostatic shaker at 25 °C and 150 rpm for 24 hours. The resulting surfactant-modified zeolite (SMZ) was centrifuged at 6000 rpm for 10 minutes, washed three times with distilled water, and then dried at 70 °C for 24 hours (Dionisiou et al., 2013; Schick et al., 2012).

Batch adsorption studies were conducted to evaluate Cr(VI) removal efficiency. All experiments were performed in a thermostatic shaker at 25 °C and 200 rpm, using a constant solution volume of 100 mL. After determining the best modification route, parameters such as contact time (15-480 min), adsorbent dosage (1.0–12.5 g/L), and initial pH (3–8) were varied systematically. Cr(VI) concentrations before and after adsorption were directly measured using UV–Vis spectrophotometry at 350 nm (Sanchez-Hachair & Hofmann, 2018). Cr(VI) removal efficiency (RE, %) was calculated from Eq. 1, in which C_0 and C_e express the concentrations of Cr(VI) in solution at initial and equilibrium, respectively.

$$RE\,(\%) = \left(\frac{C_0 - C_e}{C_0}\right) \times 100 \qquad (1)$$

RESULTS and DISCUSSION

The Cr(VI) removal performance of raw and modified zeolites is presented in Figure 1. The experiments were performed without pH adjustment using an initial Cr(VI) concentration of 50 mg/L, an adsorbent dosage of 5 g/L, and a contact time of 24 h.

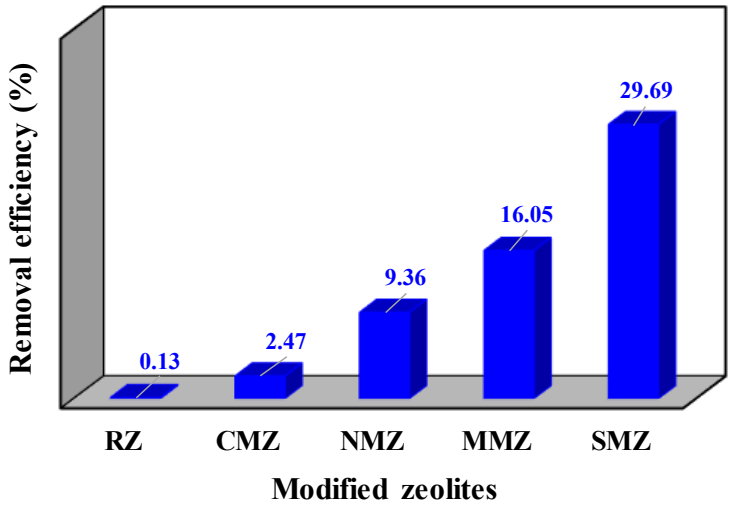

Figure 1. The effect of modification process on Cr(VI) removal efficiency.

As seen in Figure 1, the removal efficiency of Cr(VI) increased significantly after magnesium salt and especially cationic surfactant modifications. In particular, while RZ showed only 0.13% removal efficiency, markedly higher values of 9.36% and 16.05% were obtained for NMZ and MMZ, respectively. This improvement can be attributed to enhanced surface charge introduced by cation exchange. The SMZ sample, modified with CTAB, exhibited the highest performance (29.69%) due to the increased availability of active adsorption sites and the formation of a positively charged surface that facilitates electrostatic attraction of negatively charged chromate ions (Song et al., 2015). Therefore, SMZ was further investigated for the effects of contact time, adsorbent dosage and initial pH.

The effect of contact time (15–480 min) was examined under natural pH (≈ 5.5) using an initial concentration of 25 mg/L and SMZ dosage of 10 g/L. As shown in Figure 2, the adsorption of Cr(VI) on SMZ increased rapidly during the initial stage and reached equilibrium after about 120 min. In particular, the removal efficiency increased from 83.01% to 94.72% as the contact time was extended from 15 to 120 min, beyond

which minor increases up to 95.11% and 95.37% were noted at 240 and 480 min, respectively. The rapid initial adsorption can be attributed to the abundance of available surface sites, while the plateau indicates that the adsorption reached saturation. This behavior is typical for monolayer adsorption processes where surface coverage becomes limited over time. The optimum contact time was determined as 120 min, which was then used to examine the effects of dosage and initial pH.

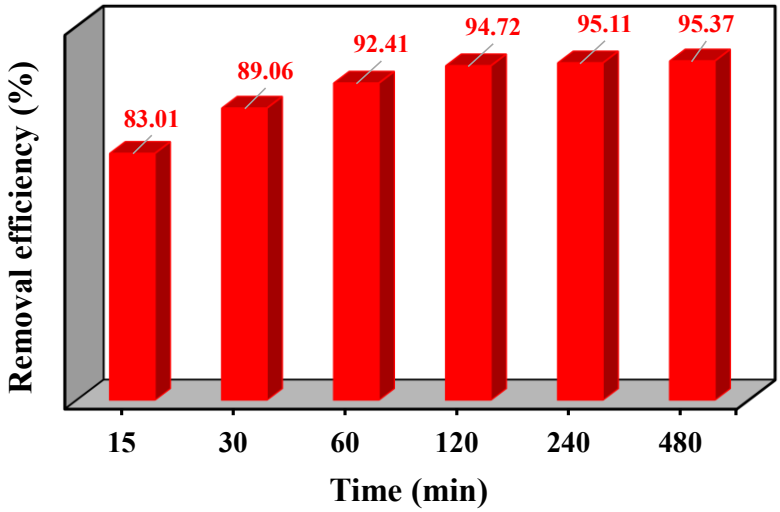

Figure 2. The effect of contact time on the removal efficiency of Cr(VI).

The influence of SMZ dosage (1.0–12.5 g/L) was examined at 120 min under natural pH using an initial Cr(VI) concentration of 25 mg/L, and the results obtained are presented in Figure 3. As seen in Figure 3, increasing SMZ dosage from 1.0 to 7.5 g/L resulted in an almost steady rise in Cr(VI) removal efficiency from 19.82% to 86.62%. This can be explained by the greater number of active binding sites (Hailu et al., 2017). The increasing rate became significantly slower beyond 7.5 g/L, and the efficiency reached to 94.72% for 10 g/L. A negligible increase to 95.24% was then noted for 12.5 g/L. Considering the balance between maximizing efficiency and maintaining practical operational conditions, 10 g/L was selected as the optimum SMZ dosage.

The effect of initial pH (3–8) was examined at 120 min using an initial Cr(VI) concentration of 25 mg/L and SMZ dosage of 10 g/L. As shown in Figure 4, the initial pH of the solution had a profound influence on the Cr(VI) removal efficiency. The maximum removal efficiency of 96.01% was achieved at pH 5. As the pH increased, the efficiency declined gradually to 92.41% at pH 6, and then sharply to 79.15% and 65.89% at pH 7 and 8, respectively. On the other hand, the efficiency decreased more gradually to 90.60% and 85.71% at pH 4 and 3, respectively.

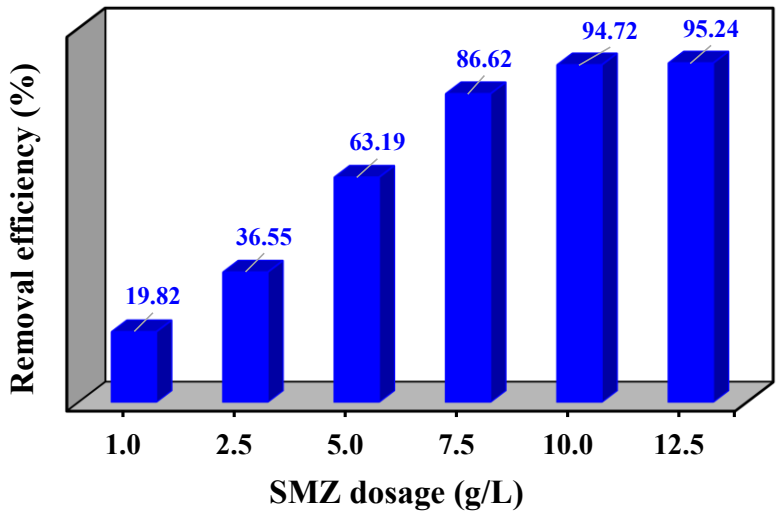

Figure 3. The effect of SMZ dosage on the removal efficiency of Cr(VI).

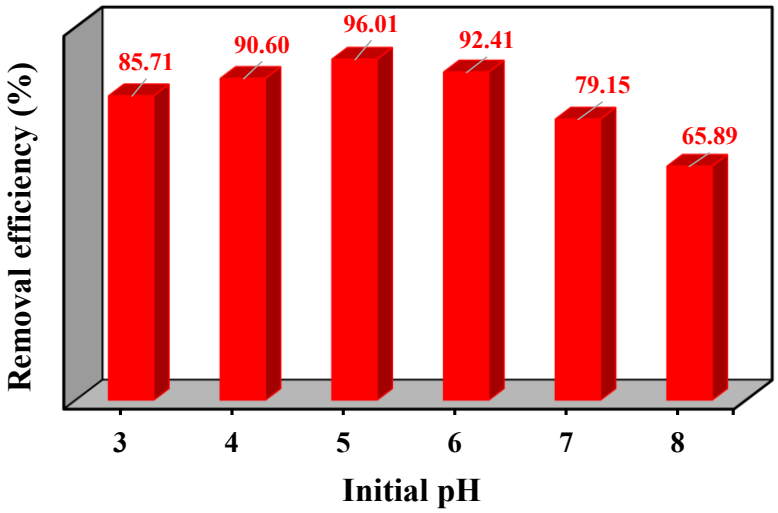

Figure 4. The effect of initial pH on the removal efficiency of Cr(VI).

This strong pH dependence is directly related to the surface charge of the SMZ adsorbent and the speciation of Cr(VI) in aqueous solution. At low pH, the surface of the CTAB-modified zeolite is strongly positively charged, and the predominant Cr(VI) species is the monovalent hydrogen chromate ion ($HCrO_4^-$). This leads to strong electrostatic attraction and high adsorption capacity. As the pH increases, the concentration of OH^- ions rises, which competes with Cr(VI) anions for adsorption sites. Furthermore, the surface of the SMZ becomes less positively charged, reducing the electrostatic driving force for adsorption. At neutral to basic pH, the predominant Cr(VI) species is the divalent chromate ion (CrO_4^{2-}), which experiences greater electrostatic repulsion from the increasingly neutral or negatively charged adsorbent surface, resulting in the observed decrease in removal efficiency (Hailu et al., 2017; Ren et al., 2016).

CONCLUSION

In conclusion, surfactant modification with CTAB transforms natural zeolite into a highly effective and low-cost adsorbent for Cr(VI) decontamination. The findings provide clear operational guidelines, emphasizing the necessity of acidic conditions for optimal performance, for its potential application in treating industrial wastewater contaminated with this hazardous heavy metal.

Abstract

Heterocyclic compounds play a significant role in modern medicinal chemistry due to their structural diversity and broad biological applications. Among these compounds, the 1,3,4-thiadiazole nucleus stands out as a valuable pharmacophore due to its significant physicochemical properties and broad pharmacological activities. This is evidenced by the fact that many FDA-approved drugs currently contain a 1,3,4-thiadiazole ring (acetazolamide and methazolamide (diuretic, carbonic anhydrase inhibitor), sulfamethizole (antimicrobial), desaglybuzole (hypoglycemic agent), litronesib, and filanesib (anticancer)). The chromone skeleton, another important structure, forms the core of flavones and exhibits a variety of biological activities. Hydrazones are chemical structures that contribute to bioactivity through the –NH–N=CH– functionality, which supports biological interactions. In this study, a five-step synthesis route was successfully carried out to produce a new chromone-1,3,4-thiadiazole hydrazone hybrid containing fluorobenzyl. In the first step, p-Fluorobenzyl isothiocyanate was reacted with hydrazine hydrate in ethanol in an ice bath to obtain the thiocarbamoyl hydrazide derivative **(1)**. Then, to generate the 1,3,4-thiadiazole ring **(2)**, a cyclization step was conducted with the thiocarbamoyl hydrazide derivative **(1)** in the presence of carbon disulfide and sodium hydroxide under reflux in ethanol. Subsequently, the obtained intermediate **(2)** was subjected to S-alkylation with ethyl chloroacetate in acetone under reflux in the presence of potassium carbonate, affording the S-ethoxycarbonylmethyl-substituted thiadiazole derivative **(3)**. In the fourth step, the mixture of intermediate **(3)** and hydrazine hydrate in ethanol was boiled under reflux. The resulting solid product was collected by filtration, washed with cold ethanol, and dried to form the intermediate **(4)**. The last step, the 1,3,4-thiadiazole hydrazine derivative **(4)**, was boiled with 3-formyl-6-nitrochromone under reflux in the presence of ethanol to construct the target compound, the fluorobenzyl-containing chromone-1,3,4-thiadiazole hydrazone derivative **(5)**. The final structure was confirmed by ^{1}H-NMR and ^{13}C-NMR spectroscopic methods. Therefore, the existence of a new hybrid structure predicted to have broad biological activity by integrating these three pharmacophores into a single molecule has been demonstrated.

Keywords: 1,3,4-Thiadiazole, Chromone, Hydrazone, Fluorobenzyl derivative, Multi-pharmacophore hybrid molecules, NMR spectroscopy.

INTRODUCTION

Heterocyclic compounds are ring structures containing at least one heteroatom and constitute one of the most important subfields of organic chemistry. Heterocyclic systems containing heteroatoms such as nitrogen, oxygen, and sulfur, as well as phosphorus, magnesium, and selenium, are also common. These rings play critical roles in the structure of DNA, RNA, chlorophyll, hemoglobin, vitamins, amino acids, and other biomolecules (Abdel-Hafez, 2008). New-age drug discovery relies heavily on heterocyclic molecules. Today, more than 90% of commercially available drugs contain heterocyclic derivatives. Heterocyclic compounds are the primary pharmacophores of many natural and synthetic drugs, such as papaverine, morphine, diazepam, chlorpromazine, isoniazid, and metronidazole, and these molecules participate in many biochemical reactions in the body (Dua et al., 2011; Chin et al., 2006; Hughes and Shanks, 2002; Koehn and Carter, 2005; Karthikeyan et al., 2023). Synthetic heterocyclic derivatives, in particular, have a wide range of applications in medicinal chemistry due to their antibacterial, antifungal, antimycobacterial, antiviral, anthelmintic, anticancer, anti-inflammatory, analgesic, anticonvulsant, and many other therapeutic effects (Jampilek, J., 2019; Mallappa et al., 2025). To improve activity, selectivity, metabolic stability, and physicochemical characteristics, new synthetic methods and functionalization strategies are frequently needed during the clinical candidate discovery phase for small structural modifications, like methyl or fluorine additions, on the

heterocyclic skeleton (Taylor et al., 2016). Research interest in heterocyclic compounds is constantly on the rise due to their high chemical adaptability, their ability to meet the diverse needs of biological systems, and their versatile pharmacological activities. As a result, these compounds are at the center of the interaction between biology and chemistry.

Thiadiazoles, with the chemical formula $C_2H_2N_2S$, are aromatic heterocyclic and unsaturated organic compounds belonging to the azole family. Their five-membered rings containing two nitrogen atoms and one sulfur atom form the basis of the chemical reactivity and pharmacological properties specific to this class. This structure, which is rarely found in nature, allows the formation of four isomers: 1,2,3-, 1,2,4-, 1,2,5-, and 1,3,4-thiadiazole, as a result of different arrangements of nitrogen, sulfur, and carbon atoms (Hu et al., 2014). Among these isomers, 1,3,4-thiadiazole derivatives are the most investigated group in the literature due to their broad biological activity profiles and have been reported to exhibit many pharmacological activities, including antifungal (Karaburun et al., 2018), antimicrobial (El-Enany et al., 2021), anti-inflammatory (Gomha et al., 2017), and anticancer (Altintop et al., 2019). Recent studies have demonstrated that compounds with this nucleus can also exhibit antidiabetic, anticonvulsant, antituberculosis, antiviral, analgesic, antidepressant, anxiolytic, antihypertensive, local anesthetic, and various enzyme inhibitory properties. Advances in synthetic strategies have enabled the efficient addition of different substituents to the thiadiazole ring, enabling improved biological and chemical properties (Kumar et al., 2013; Zaki et al., 2025). However, challenges remain in optimizing reaction conditions, scalability, and selectivity, suggesting that this area remains open for future research.

Chromones, which address a broad therapeutic spectrum in pharmaceutical chemistry, provide a unique scaffold thanks to a γ-pyrone core fused to a benzo ring and have proven their clinical value with approved drugs such as disodium cromoglicate and flavoxate. Advances in synthetic methods have enabled the development of novel chromone derivatives that can selectively modulate diverse targets such as cancer, inflammation, diabetes, infectious diseases, and neurodegenerative disorders (Reis et al., 2017; Keri et al., 2014; Kaishap et al., 2025). Furthermore, their use as imaging probes and regulators of pharmacologically important targets such as pyridoxal phosphatase (PDXP) further expands their role in modern drug discovery (Kaishap et al., 2025). The chromone skeleton is a frequently preferred core structure in medicinal chemistry due to its amenability to structural modification, functional adaptability, and synthetic accessibility, and forms the fundamental backbone of many flavanols, flavones, isoflavones, and flavonoids (Lewandowski et al., 2020). Although there are studies on the chemical properties and biological activities of these compounds, the limited number of studies that comprehensively examine the molecular structure-activity relationships of chromones creates a significant gap in the literature.

Hydrazones, regarded as universal structural units, are significant synthetic chemicals utilized in the generation of carbon-nitrogen and nitrogen-heteroatom linkages. Hydrazones serve as useful intermediates in chemical synthesis, typically produced through the condensation of hydrazine with an aldehyde or ketone. Comprehensive research has shown that hydrazone derivatives serve as efficient precursors in the synthesis of diverse heterocyclic compounds, including pyrazoles, pyrazines, indazoles, tetrazoles, oxadiazoles, and thiadiazoles (Lv et al., 2021).

The aim of this study was to synthesize a new fluorobenzyl derivative of the chromone–1,3,4-thiadiazole–hydrazone hybrids, which have been reported only in the literature, and to characterize the resulting structure in detail using various spectroscopic techniques. It is anticipated that this new hybrid structure will contribute to the chemical diversity of heterocyclic systems and serve as a valuable example to the literature.

MATERIALS AND METHODS

Chemistry

All chemicals used throughout the synthetic studies were obtained from Sigma-Aldrich Chemicals (Sigma-Aldrich Corp., St. Louis, MO, USA) or Merck Chemicals (Merck KGaA, Darmstadt, Germany). The melting points of the final products were measured using an MP90 digital melting point apparatus (Mettler Toledo, OH, USA), and the values are reported without correction. The ^{1}H and ^{13}C NMR spectra of the synthesized compounds were recorded on Bruker FT-NMR spectrometers operating at 400 MHz and 100 MHz, respectively (Bruker Bioscience, Billerica, MA, USA), using DMSO-d6 as the solvent. In the NMR data, splitting patterns were identified as follows: s (singlet), d (doublet), t (triplet), and m (multiplet). Coupling constants (J) are expressed in Hertz. Reaction progress was routinely followed by thin-layer chromatography (TLC) on Silica Gel 60 F254 plates (Merck KGaA, Darmstadt, Germany).

Synthesis of N-(4-fluorobenzyl)hydrazinecarbothioamide (1):

4-Fluorobenzyl isothiocyanate was dissolved in ethanol (30 mL). Excess hydrazine hydrate was added dropwise in an ice bath for 2 h, and the precipitated product was filtered off. The residue was then dried and recrystallized from EtOH.

Synthesis of 5-(4-fluorobenzyl) amino)-1,3,4-thiadiazole-2-thiol (2):

A mixture of N-(4-fluorobenzyl)hydrazinecarbothioamide **(1)** (0.02 mol, 3.70 g) and carbon disulphide (0.024 mol, 1.44 mL) was added to EtOH (40 mL) containing NaOH (0.024 mol, 0.96 g) and refluxed for 4 h. After completion of the reaction, the mixture was poured into iced water and acidified with 20% HCl to pH 4–5. The precipitated product was filtered, washed with water, dried, and recrystallized from EtOH.

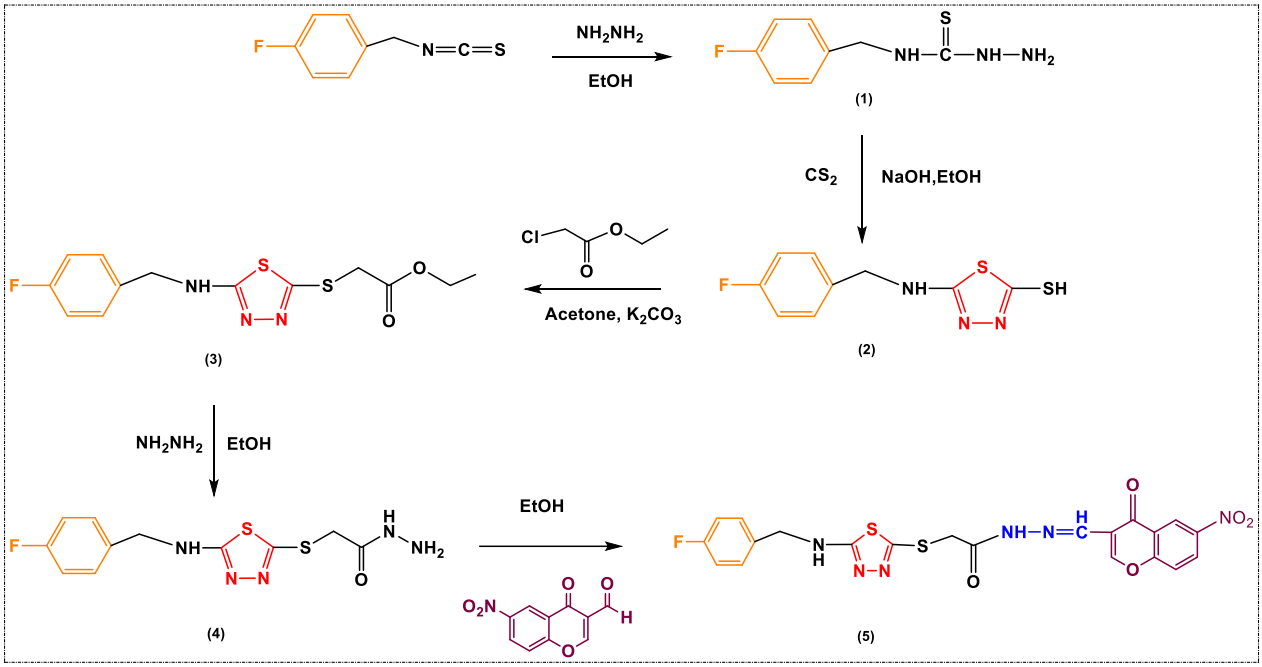
Synthesis of ethyl 2-((5-(4-fluorobenzyl) amino)-1,3,4-thiadiazol-2-yl) thio)acetate (3):

5-((4-fluorobenzyl) amino)-1,3,4-thiadiazole-2-thiol **(2)** and chloroethylacetate are dissolved in acetone. Potassium carbonate is added to it. The mixture is stirred under reflux for 4 hours at 40°C. The precipitated product is filtered off, washed with water and crystallized from ethanol.

Synthesis of 2-((5-((4-fluorobenzyl)amino)-1,3,4-thiadiazol-2-yl)thio)acetohydrazide (4):

Ethyl 2-((5-(4-fluorobenzyl) amino)-1,3,4-thiadiazol-2-yl) thio)acetate **(3)** was dissolved in ethanol and hydrazine hydrate was added. The mixture was heated under reflux for 2 hours and the precipitated part was filtered off.

Synthesis of 2-((5-((4-fluorobenzyl) amino)-1,3,4-thiadiazol-2-yl) thio)-N'-((6-nitro-4-oxo-4H-chromen-3-yl) methylene) acetohydrazide (5):



2-((5-((4-fluorobenzyl)amino)-1,3,4-thiadiazol-2-yl)thio)acetohydrazide **(4)** was dissolved in ethanol, and a few drops of acetic acid together with 6-nitro-4-oxo-4H-chromene-3-carbaldehyde (0.001 mol) were added. The mixture was heated under reflux for 2 hours, after which the precipitate was filtered off and crystallized from butanol.

Yield: 75%, M.P. = 136.7–138.3°C. ^{1}H-NMR (400 MHz, DMSO-*d6*): δ = 4.10 (2H, s, S-CH_2), 4.16 (2H, s, CH_2), 6.50 (1H, d, J=6.04 Hz, NH), 7.18 (2 H, s, 1,4-disubstituted benzene), 7.58–7.59 (2 H, m, 1,4-disubstituted benzene), 7.89-7.94 (1H, s, -CH), 8.40-8.42 (1 H, s, Aromatic CH), 8.50 (1H, dd, J=5.8 Hz, 0.72 Hz Aromatic CH), 8.55-8.58 (1H, s, Aromatic CH), 8.70-8.74 (1H, s, Aromatic CH), 10.39(1H, s, NH). ^{13}C-NMR (100 MHz, DMSO-*d6*): δ = 35.90, 61.77, 113.02, 116.10 (d, J (CF)=22.32 Hz), 119.55 (d, J (CF)=7.70 Hz), 121.50 (m, ArC, C-F coupling), 122.94, 123.74, 124.60, 128.89 (d, J (CF)= 5.94 Hz), 137.29 (d, J (CF)= 2.09 Hz), 144.85 (m, ArC, C-F coupling), 152.09, 156.57, 158.16, 158.94, 159.34 (m, ArC, C-F coupling), 165.56, 168.70, 175.91.

RESULTS and DISCUSSION

The synthesis scheme of the target new 1,3,4-thiadiazole-chromone-derived hydrazone compound is shown in **Scheme 1**. The synthesis first started with the preparation of N-(4-fluorobenzyl)hydrazinecarbothioamide **(1)**. For this purpose, 4-fluorobenzyl isothiocyanate was dissolved in ethanol and hydrazine hydrate was slowly added to the mixture in an ice bath. The solid precipitated at the end of the reaction was filtered and purified by recrystallization from ethanol. In the second step, thiosemicarbazide derivative **(1)** was reacted in the presence of carbon disulfide and ethanolic sodium hydroxide to obtain 5-(4-fluorobenzylamino)-1,3,4-thiadiazole-2-thiol **(2)** via cyclization. The reaction mixture was poured into ice water and the pH was adjusted to 4–5 with 20% HCl to precipitate the product. The resulting solid was filtered and washed and then crystallized from ethanol. In the third step, compound **(2)** was S-alkylated with chloroethylacetate in acetone in the presence of potassium carbonate to synthesize ethyl 2-((5-(4-fluorobenzyl)amino)-1,3,4-thiadiazol-2-yl)thioacetate **(3)**. The target product was formed by heating the mixture under reflux for four hours. By hydrazinolysis of the ester group, compound **(3)** was reacted with ethanolic hydrazine hydrate to obtain the main intermediate, 2-((5-(4-fluorobenzyl)amino)-1,3,4-thiadiazol-2-yl)thioacetohydrazide **(4)**. This hydrazide derivative was used as the basic building block in the condensation step. In the last step, hydrazide compound **(4)** was converted to the corresponding hydrazone derivative by heating with 6-nitro-4-oxo-4H-chromene-3-carboxyaldehyde under the catalysis of acetic acid in an ethanolic medium under reflux for 2 hours. The obtained solid was filtered, and the pure product was obtained by crystallization from butanol. The final compound, 2-((5-(4-fluorobenzyl)amino)-1,3,4-thiadiazol-2-yl)thio)-N'((6-nitro-4-oxo-4H-chromen-3-

yl)methylene)acetohydrazide **(5)**, has a hybrid structure that combines three basic pharmacophores: a 4-fluorobenzylamino unit, a 1,3,4-thiadiazole ring, and a hydrazone chain. The combination of these units in a single structure is anticipated to contribute to the broad biological activity potential of the molecule.

Scheme 1. Synthetic strategy for compounds 1-5.

Structural verification was accomplished using ^{1}H NMR and ^{13}C NMR spectroscopic analyses. In the ^{1}H NMR spectrum, the S-CH_2 and the CH_2 group adjacent to the carbonyl appeared as singlets at δ 4.10 and 4.16 ppm, respectively. The NH proton attached to the aryl group was observed as a doublet at δ 6.50 ppm (J = 6.04 Hz), while the imine proton (–CH=N–) appeared as a singlet at δ 7.89–7.94 ppm. The aromatic region displayed signals consistent with both the 1,4-disubstituted fluorobenzyl moiety and the chromone core. Fluorobenzyl protons resonated at δ 7.18 and 7.58–7.59 ppm, whereas chromone protons appeared within the δ 8.40–8.74 ppm range. Notably, the proton at δ 8.50 ppm exhibited a dd splitting pattern (J = 5.8, 0.72 Hz) due to long-range ^{1}H–^{19}F coupling. The acidic NH proton was detected as a singlet around δ 10 ppm. In the ^{13}C NMR spectrum, the S-CH_2 and CONH-CH_2 carbons were observed at δ 35.90 and 61.77 ppm, respectively. The aromatic carbons bearing fluorine exhibited characteristic C–F coupling-induced splittings (e.g., δ 116.10 ppm, d, J(CF) = 22.32 Hz; 119.55 ppm, d, J(CF) = 7.70 Hz; 128.89 ppm, d, J(CF) = 5.94 Hz). The chromone carbonyl carbons and the hydrazide carbonyl were identified at δ 165.56, 168.70, and 175.91 ppm, confirming the conjugated structural framework.

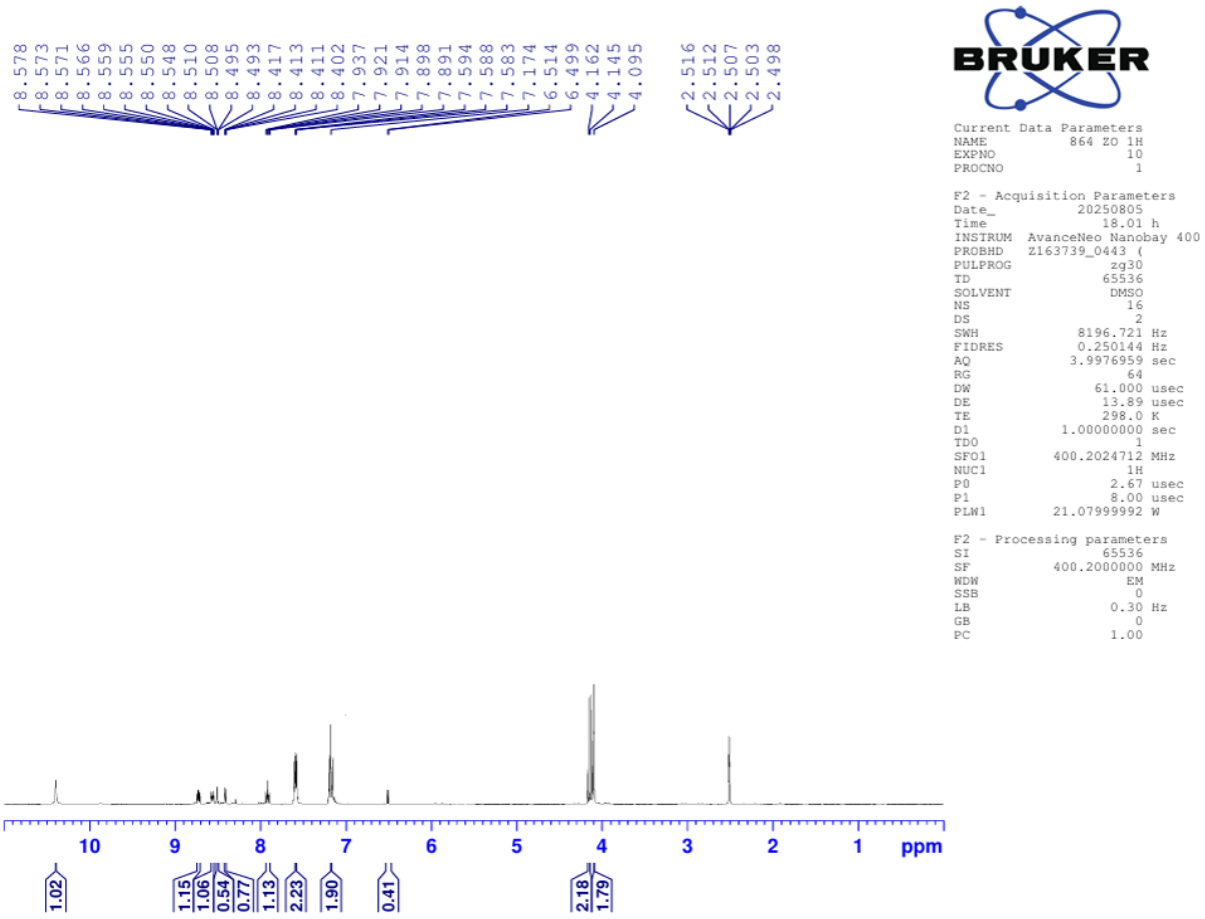


Figure 1. ^{1}H-NMR spectrum of 2-((5-((4-fluorobenzyl) amino)-1,3,4-thiadiazol-2-yl) thio)-N'-((6-nitro-4-oxo-4H-chromen-3-yl) methylene) acetohydrazide **(5)**.

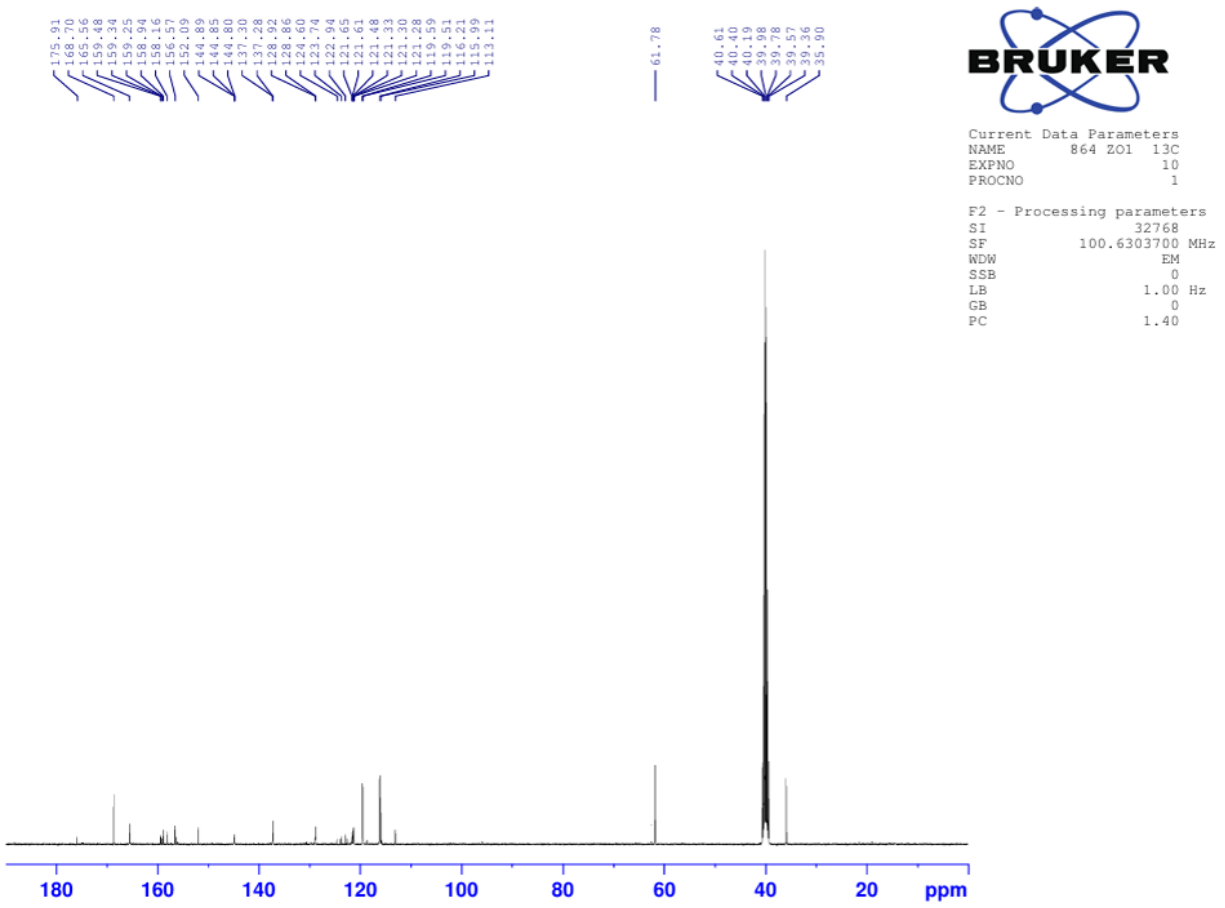

Figure 2. ^{13}C-NMR spectrum of 2-((5-((4-fluorobenzyl) amino)-1,3,4-thiadiazol-2-yl) thio)-N'-((6-nitro-4-oxo-4H-chromen-3-yl) methylene) acetohydrazide **(5)**.

CONCLUSION

In this study, a novel fluorobenzyl-substituted chromone-1,3,4-thiadiazole-hydrazone hybrid molecule was successfully synthesized via a five-step reaction. The synthetic strategy incorporated three biologically important structural motifs (chromone, 1,3,4-thiadiazole, and hydrazone) into a single molecular framework, enabling the efficient creation of a multi-pharmacophore molecule. Structural confirmation of the target compound was provided by ^{1}H-NMR and ^{13}C-NMR spectroscopy. This newly synthesized compound is expected to contribute to the molecular diversity of heterocyclic hybrid structures and serve as a promising scaffold for future biological activity screening. Further studies focusing on the evaluation of its pharmacological potential, structure-activity relationships, and molecular docking analyses are expected to expand the applicability of this hybrid framework in medicinal chemistry research.

Abstract

Nanostructured particles have a wide range of applications across many sectors, primarily in electronics, biomedicine, automotive, and chemistry. The phytogenic synthesis of zinc oxide nanoparticles (ZnO-NPs) is considered an environmentally friendly approach due to their low toxicity and biological potential. Today, ZnO-NPs are at the forefront of research due to their versatile structure, which can be applied in biomedicine, wastewater treatment, environmental remediation, and even cosmetic products. Studies have shown that ZnO-NPs produced by different methods have antimicrobial, antioxidant, and anticancer properties. Therefore, studies on the antioxidant and antibacterial activity of ZnO-NPs are increasing day by day. This study aimed to determine the MIC and MBC values of ZnO-NPs. Gram-negative (*E. coli*) and gram-positive (*S. aureus*) bacteria were used for the study. Additionally, the antioxidant activity of ZnO-NP was determined using the DPPH method.

Keywords: Zinc oxide, Antioxidant, DPPH, Antibacterial, MIC-MBC.

1. INTRODUCTION

Atoms or molecules with one or more unpaired electrons in their outer orbitals are called free radicals. Free radicals are unstable due to their unpaired electrons and react with other substances in an attempt to become stable (Karabulut & Günay, 2016).

Antioxidants are substances that protect cells against the undesirable effects of free radicals, both directly and indirectly. Compounds such as vitamins C, E, A, beta-carotene, metallothionein, NADPH, and coenzyme Q-10 belong to this group. (Mercan, 2004).

As the dimensions of materials decreased, it was recognized that they possessed superior properties, leading to the growing importance of nanoparticles. Among these superior properties are increased surface area with decreasing particle size, along with superior magnetic, electronic, optical, and thermal properties. Interest in metal oxide particles is increasing day by day due to the different properties they exhibit at the nanoscale (Kamçı et al., 2022). Zinc oxide, one of these metal oxide materials, is a semiconductor material. The high binding energy and wide bandgap of zinc oxide particles are among its most important properties. The non-toxicity and skin compatibility of zinc oxide, along with its UV-reducing effect, also enable its use in the field of human health. The ease with which ZnO nanoparticles dissolve in liquids and organic solvents also allows them to be incorporated into many material processes and contributes to their wide range of applications (Arığ, 2010). Antimicrobial resistance is one of the leading global health issues according to the World Health Organization (WHO). The indiscriminate and excessive use of antibiotics has led to the emergence of resistant microorganism strains. Due to the low effectiveness of antibiotics against resistant strains, research has shifted towards alternative approaches that could replace traditional antibiotics. With the rapid development of nanomedicine, researchers have aimed to produce solutions using nanoparticles. In many studies, ZnO-NPs have demonstrated antibacterial activity in both gram-negative and gram-positive bacterial strains (Karakaplan, 2021). The continuous emergence of bacterial resistance is forcing the scientific community to develop new antibiotic agents. Among the most promising of these new antibiotic agents are metal NPs, which

have demonstrated potent antibacterial activity in numerous studies. Even when new antibiotics are introduced to the market, antibiotic-resistant bacteria emerge within a relatively short period of time. However, it is assumed that antibacterial-active NPs have the potential to reduce or eliminate the evolution of more resistant bacteria. Because NPs target multiple biomolecules simultaneously, they prevent the development of resistant strains. NPs come into direct contact with the bacterial cell wall without penetrating the cell and exhibit a broad spectrum of antibacterial properties. (Özkara, 2025). After being synthesized for use in many fields, various activity studies are conducted on nanoparticles. It is known that zinc oxide nanoparticles (ZnO-NPs) inhibit the growth of various bacterial strains and also exhibit cytotoxic effects against various cancer cell lines (Nair et al., 2009).

2. MATERIAL AND METHODS

2.1. The Synthesis of ZnO-NPs

A total of 280 mg of zinc acetate ($Zn(CH_3COO)_2$) was mixed with oleylamine in a beaker, and the synthesis temperature was set to 240 °C. The reaction was maintained for 5 minutes, after which the mixture was allowed to cool. Once the temperature reached 70 °C, 10 mL of ethanol was added, and the ZnO piezocatalysts were collected by centrifugation.

The morphological characteristics of the ZnO nanoplates were analyzed using SEM, and the corresponding results are presented in Figure 1. As shown in the figure, all pure ZnO particles exhibited a well-defined hexagonal morphology with an average particle size of approximately 325 nm.

2.2. DPPH Scavenging Activity

To calculate the DPPH scavenging activity, ZnO-NP solutions were prepared at different concentrations of 1.25, 2.5, 5, 10, 20, and 40 mg/mL in 10% DMSO. To these samples, 100 µL was added to 0.25 mL of 1 mM DPPH and 2 mL of methanol, and the mixture was incubated for 20 minutes. (Karamaç et al., 2019). Subsequently, absorbance measurements were taken at 517 nm for the samples. DPPH scavenging activity was calculated as a percentage according to the following formula (Seyhan, 2019).

DPPH removal activity % = (Control Abs- Sample Abs)/Control Abs x 100

2.3. MIC and MBC Assay

The minimum inhibitory concentration (MIC) test was used to determine the antimicrobial activity of ZnO nanoparticles, employing *E. coli* and *S. aureus* bacteria. In this test, ZnO-NP solutions (100 µL) prepared with sterile liquid medium at different concentrations (10^{-5}, 2.5, 1.25, 0.625, 0.312, 0. 156 µg) were added to 96-well plates. The negative control well was added with 10 µL of bacterial suspension and 100 µL of sterile liquid medium. After adding the ZnO-NP solution and bacterial suspension diluted in a twofold serial manner to each well (except the negative control well), the plates were incubated at 37°C for 24 hours. Then, 15 µL of Alamar Blue was added to each well and incubated again to allow for color change. The well where the first color change occurred was reported as the MIC value. For the minimum bactericidal concentration (MBC) test, ZnO-NP solutions at concentrations corresponding to the MIC value of the bacteria, twice the MIC value, and four times the MIC value were added to liquid bacterial suspensions and incubated at 37°C for 24 hours. Subsequently, the cultures were inoculated onto solid media, and the absence of growth at the concentration where no growth was observed was reported as the MBC.

3. RESULTS AND DISCUSSION

3.1. SEM Analysis of ZnO Nanoparticles

SEM imaging (Figure X) clearly demonstrates that the synthesized ZnO nanoparticles exhibit a well-defined hexagonal plate-like morphology, consistent with the typical wurtzite crystal structure of ZnO. The particles appear uniformly distributed, with smooth surfaces and sharp edges, indicating successful crystal growth under the applied synthetic conditions. The nanoplates show relatively narrow size variation, and most structures display a consistent hexagonal geometry, confirming the formation of pure and shape-controlled ZnO nanostructures.

The dense packing observed in the micrograph further suggests minimal agglomeration, supporting the effectiveness of oleylamine as a stabilizing and structure-directing agent during the synthesis process. Overall,

the SEM results validate that the employed method enables the production of monodisperse hexagonal ZnO nanoplates with well-defined morphology.

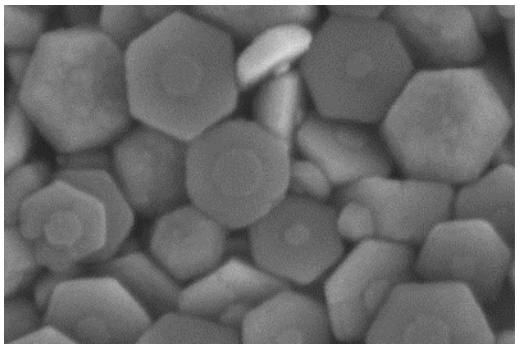

Figure 1. SEM analysis image of ZnO-NPs.

3.2. DPPH Scavenging Activity of ZnO-NPs

The DPPH scavenging activity of ZnO nanoparticles was calculated as 1.85% at the lowest concentration of 1.25 mg/mL. At a concentration of 40 mg/mL, it was calculated as 26.77%, demonstrating a remarkably high activity.

Table 1. DPPH % inhibition data values of ZnO-NPs.

Concentration (mg/mL)	1.25	2.5	5	10	20	40
DPPH Scavenging Activity (%)	1.85	3.7	4.47	15.81	25.38	26.77

Each value was expressed as mean ± SD and all experiments were performed in triplicate. The data were analyzed using Duncan's Multiple Range Test ($\alpha = 0.05$).

When reviewing the literature, the antioxidant activity of zinc oxide nanoparticles coated with Nyctanthes arbor-tristis (NA) leaf extract (ZnO-NA) was determined using the DPPH method, and the IC_{50} value was found to be 125 µg/mL (Koçak & Meydan, 2023). In another study, the DPPH scavenging percentage of ZnO nanoparticles was calculated as 45.47% at a concentration of 1 mg/mL (Denk & Tarhan, 2023). Ercan et al. (2025) reported that the DPPH scavenging activity of ZnO-NPs at a concentration of 0.5 mg/mL was 37.63%. The IC_{50} values of the DPPH radical scavenging activity of ZnO-NPs and leaf extract were found to be 18.71 ± 0.35 and 9.21 ± 0.10, respectively.

3.3. MIC and MBC Profiles of ZnO-NPs Against Test Bacteria

In the study, the MIC values of ZnO-NP were determined to be 10 µg/mL against *E. coli* and 0.625 µg/mL for *S. aureus.* According to the MBC test, the values were found to be 20 µg/mL for *E. coli* and 1.25 µg/mL against *S. aureus.*

Table 2. The MIC-MBC values of of ZnO-NPs against *E. coli* and *S. aureus* bacteria.

Bacteria	**MIC**	**MBC**
E.coli	10 µg/mL	20 µg/mL
S.aureus	0.625 µg/mL	1.25 µg/mL

A review of the literature revealed that the MIC values of ZnO-NP against *A. hydrophila* and *V. parahaemolyticus* strains were determined to be 15 and 7.5 µg/mL, respectively. (Günay et al., 2021). The MIC values of ZnO-NP synthesized with the oil of *Eucalyptus globulus* against *S. aureus* ATCC 43300 and *S. aureus* ATCC 25923 strains were observed to be 128 and 32 µg/ml, respectively (Zahra Obeızı et al., 2020). The MIC values of ZnO-NP synthesized with *Mussaenda frondosa* extract against *S. aureus* and *E. coli* strains were determined to be 54.13 µg/mL and 19.23 µg/mL, respectively (Jayappa et al., 2020). In another study,

the MIC values of ZnO-NP against *E. coli*, *S. aureus*, *P. aeruginosa*, and *E. faecalis* were found to be above 128 µg/mL (Erdoğan et al., 2019). ZnO-NP is known to inhibit the growth of various bacteria such as *C. jejeuni*, *S. enterica*, *E. coli*, *S. aureus*, and *Vibrio cholerae*. The antibacterial effect of synthesized ZnO-NP against *S. aureus* and *E. coli* has been proven to be effective against both gram-negative and gram-positive bacteria and is consistent with the literature. It has also been reported that ZnO-NP, which is found in antiseptics, is also present in many products such as anti-dandruff shampoos in cosmetics, ointments for skin rashes, mineral creams for wound healing, and medical bandages (Kuo et al., 2010).

With the rapid development of nanomedicine, researchers have aimed to produce solutions using nanoparticles. Metal oxide nanoparticles stand out due to their high stability and multiple effects against microorganisms. One of the most prominent of these is zinc oxide nanoparticles (ZnO-NP). In many studies, ZnO-NPs have demonstrated antibacterial activity in both gram-negative and gram-positive bacterial strains (Karakaplan, 2021).

Additionally, in biological systems, the excessive production of free radical species is one of the main causes of various diseases such as cancer, diabetes, cardiovascular diseases, and arthritis. All biosystems require antioxidants to a large extent for proper functioning. Consequently, there is an urgent need to research innovative and safe antioxidants produced from natural sources that are more effective and less toxic.

4. CONCLUSION

In this study, ZnO nanoparticles were successfully synthesized using a controlled chemical approach, and their morphological, antioxidant, and antibacterial properties were comprehensively evaluated. SEM analysis confirmed the formation of monodisperse ZnO nanoplates with well-defined hexagonal morphology, indicating effective crystal growth and minimal agglomeration during synthesis.

The antioxidant assessment revealed that ZnO-NPs exhibited dose-dependent DPPH radical scavenging activity, with the highest inhibition rate observed at 40 mg/mL. Although the antioxidant activity was moderate compared to several plant-mediated ZnO nanoparticle systems reported in the literature, the results demonstrate that the synthesized ZnO-NPs possess measurable free-radical scavenging potential.

The antibacterial assays showed that ZnO-NPs were highly effective against both Gram-negative (*E. coli*) and Gram-positive (*S. aureus*) bacteria, with notably low MIC and MBC values. These findings are consistent with previous studies and further support the broad-spectrum antimicrobial potential of ZnO-NPs. The strong inhibitory and bactericidal effects reflect the suitability of ZnO-NPs for potential use in biomedical, pharmaceutical, and hygienic applications.

Overall, the results of this study demonstrate that ZnO nanoparticles synthesized under the described conditions exhibit promising antioxidant and antibacterial activities. Given their biocompatibility, stability, and multifunctional nature, ZnO-NPs represent an attractive candidate for future applications in nanomedicine, antimicrobial formulations, and therapeutic antioxidant systems. Further studies exploring cytotoxicity, ROS generation, and mechanistic pathways will enhance the understanding and applicability of these nanomaterials.

Özet

Bacillus thuringiensis (Bt), sporlu ve entomopatojenik bir bakteridir. Sporulasyonu sırasında parasporal inklüzyon proteinleri üretmektedir. Bu proteinler içerisinde en çok çalışılan grubunu insektisidal özellikteki Cry proteinleri oluşturmaktadır. Bu proteinlerden bazıları insektisidal özelliklerinden bağımsız olarak kanser hücre hatlarına karşı sitotoksik aktivite gösterebilmektedir. Hemolitik olmayan ve kanser hücrelerini hedef alan bu Cry proteini grubu Parasporinler (PS) olarak bilinmektedir. Bu çalışmada 6 Bt izolatımızın çeşitli kanser hücre hatları üzerindeki sitotoksik aktivitelerinin ve parasporin (*ps*) gen içeriklerinin belirlenmesi amaçlanmıştır. Bunun için, bu izolatlardan parasporal inklüzyon proteinleri elde edilmiş ve solubilizasyonun ardından Proteinaz K ile aktifleştirilmiştir. Aktive edilen protein profili SDS-PAGE analizi ile gösterilmiştir. Bu proteinlerin sağlıklı embriyonik böbrek hücreleri (HEK-293), prostat kanseri (PC-3), akciğer kanseri (A-549), meme kanseri (MCF-7), uterus serviks kanseri hücreleri (HeLa) ve Burkitt (lenfoma) hücreleri üzerinde toksik olup olmadığı MTT analizi ile araştırılmıştır. Parasporal inklüzyonların farklı düzeylerde çeşitli hücre hatları üzerinde sitotoksisitelerinin olduğu tespit edilmiştir. Test edilen izolatlardan 19Q2, 19Q3 ve BB99 analizi yapılan tüm kanser hücre hatlarına karşı anlamlı düzeyde ($P<0.05$, $P<0.01$ veya $P<0.001$) sitotoksik aktivite göstermiştir. Üç örnek de, MCF-7 ve Burkitt hücre hatlarına karşı $P<0.01$ düzeyinde etkili olmuştur. 19Q2, 19Q3 ve BB99 izolatları ile yapılan PCR analizi sonucunda sadece BB99 izolatı *ps1* geni için pozitif sonuç vermiştir. Dolayısıyla, bu çalışmada elde edilen pozitif sonuçlar doğal Bt izolatlarımızın anti kanser ilaç geliştirilmesine katkıda bulunabilecek bir potansiyel taşıdığını ve bunun ilerleyen çalışmalarda ortaya konması gerektiğini göstermektedir.

Anahtar Kelimeler: *Bacillus thuringiensis*, parasporal protein, sitotoksisite, MTT analizi, doz-bağımlı analiz

Investigation of cytotoxic activities of *Bacillus thuringiensis* parasporal proteins on various cancer cell lines

Abstract

Bacillus thuringiensis (Bt) is a spore-forming, entomopathogenic bacterium. It produces parasporal inclusion proteins during sporulation. The most studied group of these proteins is the insecticidal Cry proteins. Some of these proteins, independent of their insecticidal properties, can exhibit cytotoxic activity against cancer cell lines. This group of Cry proteins, which is non-hemolytic and targets cancer cells, is known as parasporins (PS). This study aimed to determine the cytotoxic activities and parasporin (*ps*) gene contents of six Bt isolates on various cancer cell lines. For this purpose, parasporal inclusion proteins were isolated from these isolates and activated with Proteinase K after solubilization. The activated protein profile was demonstrated by SDS-PAGE analysis. The toxicity of these proteins on healthy embryonic kidney cells (HEK-293), prostate cancer (PC-3), lung cancer (A-549), breast cancer (MCF-7), uterine cervix cancer cells (HeLa) and Burkitt (lymphoma) cells was investigated using MTT analysis. Parasporal inclusions were found to have varying levels of cytotoxicity on various cell lines. Of the isolates tested, 19Q2, 19Q3 and BB99 showed significant cytotoxic activity ($P<0.05$, $P<0.01$ or $P<0.001$) against all cancer cell lines analyzed. All three samples were active against MCF-7 and Burkitt cell lines at $P<0.01$. As a result of PCR analysis performed with 19Q2, 19Q3 and BB99 isolates, only isolate BB99 was positive for the *ps1* gene. Therefore, the positive results obtained in this study indicate that our natural Bt isolates have the potential to contribute to the development of anticancer drugs and this should be demonstrated in further studies.

Keywords: *Bacillus thuringiensis*, parasporal protein, cytotoxicity, MTT assay, dose-dependent assay

GİRİŞ

Bacillus thuringiensis (Bt); toprak, bitki ve böceklerde yaygın olarak bulunan Gram pozitif sporlu bir bakteridir (Schnepf ve ark., 1998). Doğada, Bt tarafından üretilen, farklı etki mekanizmalarına sahip birçok toksin bulunmaktadır. Bunlar arasında en iyi bilinen ve üzerinde çalışılan toksinler insektisidal (Palma ve ark., 2014), antimikrobiyal (Doshi ve ark., 2024), antifungal (Martinez-Zavala ve ark., 2020) ve anti kanser (Santos ve ark., 2022) özellikler taşımaktadır. Bu toksinlerin başında ise yapısı en iyi aydınlatılan ve hakkında en çok araştırma bulunan insektisidal proteinler gelmektedir. Kristal (Cry), sitolitik (Cyt) ve vejetatif insektisidal proteinler (Vip) tarım zararlılarının kontrolünde kullanılmaktadır. Bunlardan üzerinde en çok çalışılmış grup olan Cry proteinleri belirli böcek takımlarına karşı spesifik insektisidal aktivite göstermektedir. Protoksin formunda sentezlenen proteinler proteolitik kesim sonucu aktif toksin formuna dönüşmekte ve etki edeceği hücre membran reseptörlerine bağlanmaktadır. Bt, ürettiği bu toksinler sayesinde uzun yıllardır başarılı bir entomopatojen olarak biyolojik mücadelede görev almaktadır. Bakteriden elde edilen toksin formulasyonları sprey şeklinde bitkilere uygulanmakta ya da transgenik Bt ürünleri elde edilerek mücadele edilmektedir (Palma ve ark., 2014).

İnsektisidal özellikteki toksinlerin yanı sıra, Bt suşlarının son yıllarda anti kanser özelliği oldukça önem kazanmıştır. Kanser, dünyada en çok görülen ölümcül hastalıklardan birisidir ve ölüm oranı her geçen yıl artmaktadır. Geleneksel tedavi yöntemlerine devam edilmekte, ancak yan etkilerinden dolayı alternatif tedavi yolları aranmaktadır. Bu durum, kanser tedavisinde biyopreparatlara olan ilginin artmasına sebep olmuştur (Alarcón-Aldana ve ark., 2024). Bt'nin anti kanser özelliğinin keşfi (Ohba ve ark., 2009) bu mücadelede yeni bir umut ışığı olmuştur.

Mizuki ve ark. (1999), parasporal inklüzyon proteinleri hemolitik olmayan ancak insan kanser hücrelerine karşı sitosidal olan *B. thuringiensis* suşlarının geniş çaplı taramasını yapmışlardır. Mizuki ve ark. (2000) antikanser aktivite gösteren ve hemolitik olmayan A1190 suşunun karakterizasyonu sonucunda 81 kDa'luk yeni bir protein tanımlamışlar ve Parasporin olarak isimlendirmişlerdir. Parasporin ilk tanımlandığında hemolitik ve insektisidal olmayan ve insan kanser hücrelerini öldürebilen proteinler olarak tanımlanmıştır. Daha sonra yapılan çalışmalarda bazı parasporinlerin hem insektisidal hem de anti kanser etki gösterdikleri görülmüş ve bu tanımlamadan insektisidal olmayan kavramı çıkartılmıştır. Bir Cry proteini sınıfı olan parasporinler bugüne kadar 6 gruba (PS1-PS6) ayrılmıştır (Aberkane ve ark. 2020). PS'lerin çeşitli hücre hatları üzerinde sitotoksik etkilerini belirlemeye yönelik birçok çalışma mevcuttur (Santos ve ark., 2022).

Bu çalışmada Bt koleksiyonumuzda bulunan ve kristal oluşumu iyi olan bazı Bt izolatlarımız seçilerek, bu izolatların spor-kristal karışımlarının, prostat kanseri, akciğer kanseri, meme kanseri, uterus serviks kanseri ve lenfoma kanser hücre hatları üzerindeki sitotoksik etkilerinin belirlenmesi amaçlanmıştır. Bunun için: 1. Bt izolatlarından parasporal inklüzyonlar elde edilerek, protoksin enzim ile aktive edilmiştir. 2. MTT analizi ile toksinlerin sitotoksik aktiviteleri belirlenmiştir. 3. Anlamlı derecede sitotoksisite gösteren izolatların PCR ile parasporin gen içerikleri araştırılmıştır. Sitotoksik aktivite gösteren Bt izolatlarının bulunması, kanser ile mücadelede kullanılabilecek biyopreparatların geliştirilmesine katkıda bulunabilecektir.

MATERYAL VE METOT

Bakteri izolatları

Bu çalışmada kullanılan Bt izolatları (6A, 60Q2, 85PPb, 125Q, 19Q2, 19Q3 ve BB99), Muğla Sıtkı Koçman Üniversitesi, Biyoloji Bölümü, Moleküler Biyoloji Laboratuvarı'nda Prof. Dr. Hatice Güneş'e ait Bt koleksiyonundan temin edilmiştir.

Kanser hücre hatları

Bu çalışmada, prostat kanseri (PC-3), akciğer kanseri (A-549), meme kanseri (MCF-7), Uterus serviks kanseri hücreleri (HeLa), Burkitt (lenfoma) olmak üzere 5 farklı kanser hücre hattı kullanılmıştır. Sağlıklı hücre hattı olarak insan embriyonik böbrek hücreleri (HEK-293) seçilmiştir. Hücreler %10 fetal bovin serum ve 100 µg/ml penisilin/streptomisin içeren RPMI 1640 besi ortamında, 37°C'de %5 CO_2, %95 hava içeren nemlendirilmiş inkübatörde kültüre edilmiştir.

Parasporal inklüzyon proteinlerin eldesi ve aktivasyonu

Bt örnekleri Nutrient agar'da 30 °C'de 4 gün büyütülmüştür. Hücreler toplanıp distile su ile iki defa yıkanmıştır. Elde edilen spor-kristal karışımı 500 µl karbonat tamponunda (56 mM Na_2CO_3 pH 11,4; 11mM DTT) 37 °C'de 1 saat çözündürülmüşür. 13,200 rpm'de 2 dk santrifüj yapılarak çözünen proteinin bulunduğu

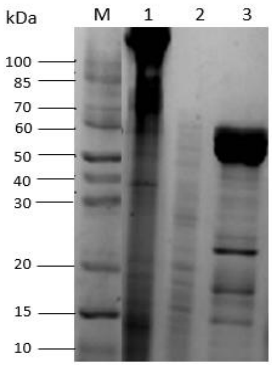
süpernatant elde edilmiştir. Supernatant pH'sı 1M Tris-HCl (pH 4.98) ile 8'e ayarlanmıştır. Çözünen proteinler 150 µg/ml Proteinaz K ile muamele edilmiş ve 37 °C'de 1 saat inkübe edilmiştir. Son konsantrasyonu 1mM olacak şekilde PMSF eklenerek proteolitik sindirim sonlandırılmıştır (Bresseur ve ark., 2015).

MTT analizi

Bt izolatlarından elde edilen parasporal proteinlerin; PC-3, A-549, MCF-7, HeLa ve Burkitt kanser hücre hatları ve sağlıklı hücre hattı HEK-293 üzerindeki sitotoksik etkileri MTT analizi ile tespit edilmiştir. 2×10^4 hücre/kuyu içeren hücreler (90 µl) 96 kuyulu plakalara ekilmiş ve %5 CO_2 ve %98 nem inkübatöründe 37 °C'de 16-20 saat inkübe edilmiştir. Daha sonra, Proteinaz K ile aktive edilmiş ve konsantrasyonu 20 µg/ml'ye ayarlanmış parasporal kristal proteinler kuyulara eklenerek 37 °C'de 48 saat inkübe edilmiştir. İnkübasyonun ardından, plakalardaki besiyeri 100 µl yeni besiyeri ile değiştirilmiştir. Yapışmayan Burkitt hücreleri için, hücre kültürü kapları 800 rpm'de 6 dakika santrifüj edilmiş ve yeni besiyeri eklenmiştir. Ardından, kuyulara 1:10 oranında MTT solusyonu (5 mg/ml) eklenmiştir. 37 °C'de, 4 saat inkübasyonun ardından, 100 µl DMSO eklenerek karışması sağlanmıştır. OD_{540} değeri mikroplaka okuyucu (Thermo Fisher Scientific) ile ölçülmüştür. Denemeler üç tekrarlı yapılmıştır.

Parasporin gen taraması

19Q2, 19Q3 ve BB99 Bt izolatlarının genomik DNA'ları kit (Exgene Clinic SV) ile izole edilmiştir. Bu izolatların *ps1*, *ps2*, *ps3*, *ps4*, *ps5* veya *ps6* parasporin genlerini taşıyıp taşımadıkları PCR analizi ile test edilmiştir. PCR analizi, Kesik Oktay (2019)'nin kullandıkları primer çiftleri ve PCR koşullarına göre yapılmıştır.

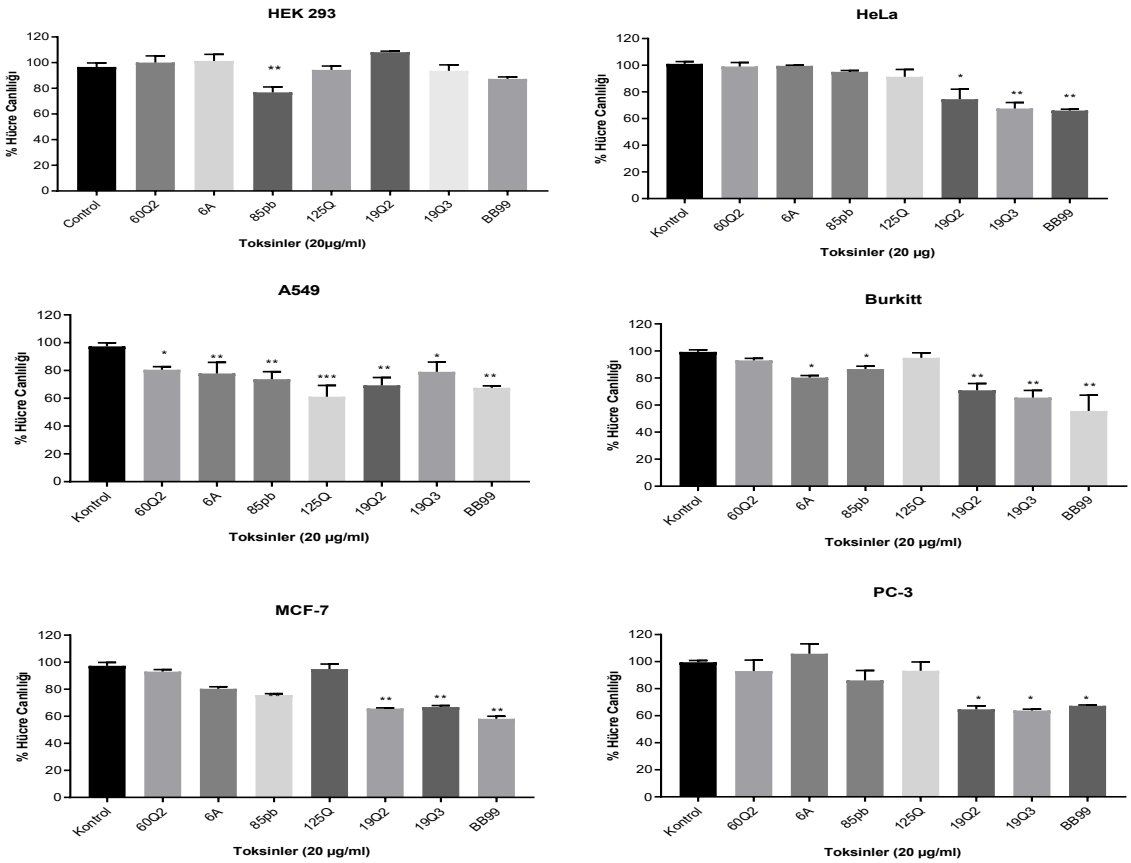


İstatistiksel analizler

Tüm analizlerde GraphPad Prism 7 programı kullanılmıştır. Sitotoksisite deneyleri sonucunda uygulamalar arasında fark olup olmadığı, tek yönlü varyans analizi (ANOVA) ile değerlendirilmiştir. Uygulamaların kıyaslanmasında Dunnett testi kullanılmıştır.

BULGULAR

Parasporal proteinlerin elde edilmesi



Sitotoksik aktivite denemelerinde kullanılmak üzere 6 Bt izolatına ait parasporal proteinler elde edilmiştir. Örnekler sırasıyla spor-kristal karışımı, alkali koşullarda solubilize edilmiş protein karışımı ve Proteinaz K ile kesime uğratılmış proteinler olarak elde edilmiş ve protein profilleri SDS-PAGE yöntemi ile belirlenmiştir. Solubilizasyon sonrasında profil bant sayısında belirgin bir azalma olduğu görülmektedir. Proteinaz K ile kesim sonucundaysa, düşük moleküler ağırlığa sahip yeni bantların oluştuğu ve aktif toksinin elde edildiği gösterilmiştir (Şekil 1).

Şekil 1. 85PPb izolatına ait parasporal proteinlerin protein profili. M: DNA Marker, 1: spor-kristal karışımı, 2: alkalide çözülmüş protein karışımı, 3: Proteinaz K ile kesilmiş protein karışımı

Sitotoksik aktivite

6A, 60Q2, 85PPb, 125Q, 19Q2, 19Q3 ve BB99 izolatlarından izole edildikten sonra Proteinaz K ile kesilip aktif formu elde edilen parasporal proteinlerin sitotoksik etkileri PC-3, A-549, MCF-7, HeLa ve Burkitt kanser hücre hatları ve sağlıklı hücre hattı üzerinde test edilmiştir.

Şekil 2. Bt izolatlarının çeşitli kanser hücre hatları üzerindeki sitotoksik etkileri *: P<0.05; **: P<0.01; ***:P<0.001, ****:P<0.0001

HEK-293 üzerinde sadece 85PPb izolatına ait parasporal proteinler hücre canlılığında anlamlı bir azalmaya sebep olmuş, diğer parasporal proteinlerde ise bu etki gözlenmemiştir (Şekil 2A). Test edilen bazı örneklerin P<0.05, P<0.01 veya P<0.001 anlam düzeylerinde çeşitli hücre hatları üzerinde sitotoksisitelerinin olduğu tespit edilmiştir (Şekil 2B, C, D, E, F). 19Q2, 19Q3 ve BB99 izolatlarından elde edilen parasporal proteinlerin, analizi yapılan tüm kanser hücre hatlarına karşı anlamlı düzeyde sitotoksik aktivite gösterdiği bulunmuştur. Her üç parasporal protein de en anlamlı etkiyi P<0.01 düzeyinde MCF-7 ve Burkitt hücre hatlarına karşı göstermiştir (Şekil 2D ve E).

PCR analizi

19Q2, 19Q3 ve BB99 Bt izolatlarının *ps1*, *ps2*, *ps3*, *ps4*, *ps5* ve *ps6* gen içerikleri PCR analizi ile belirlenmiştir. BB99 izolatı 511 bç uzunluğundaki *ps1* geni için pozitif bulunmuştur. 19Q2 ve 19Q3 izolatlarının ise bu genlerden hiçbirini taşımadığı görülmüştür (Data gösterilmemiştir).

TARTIŞMA

Bu çalışma, *Bt* izolatlarımızın sitotoksik aktivitelerini tespit etmek amacıyla yapılmıştır. *Bt* koleksiyonumuzdan seçilen 6 örneğin parasporal proteinlerinin sitotoksik aktiviteleri PC-3, A-549, MCF-7, HeLa ve Burkitt kanser hücre hatları ve sağlıklı HEK-293 hücre hattı üzerinde test edilmiştir. HEK-293 hücreleri üzerinde sadece 85PPb izolatının parasporal proteinleri anlamlı düzeyde hücre canlılığını azaltmıştır, diğer izolatların parasporal proteinleri ise hücre canlılığını anlamlı düzeyde etkilememiştir. Daha önce yapılan araştırmalar Bt izolatlarının farklı hücre hatlarına karşı sitotoksik etkiye sahip olduğunu ortaya koymuştur (Santos ve ark., 2022). Bu çalışmada, sitotoksik aktiviteyi belirlemek için yapılan MTT analizi sonucunda sağlıklı hücre hattının hücre canlılığını etkilemeyen, ancak kanser hücre hatlarının hücre canlılığını kontrole kıyasla anlamlı düzeyde düşüren 5 Bt izolatının olduğu tespit edilmiştir. Bu izolatlar içerisinden 19Q2, 19Q3 ve BB99 Bt izolatlarının test edilmiş tüm hücre hatlarında hücre canlılığını azalttığı gözlenmiştir. Bazı bakteriler tarafından sentezlenerek sitotoksik aktivite gösteren bileşenler Parasporinler olarak bilinmektedir (Ohba ve ark., 2009). Bu yüzden, etkili olan bu üç izolatın sitotoksik aktivitelerinin Parasporin proteinlerinden

kaynaklanıp kaynaklanmadığını test etmek için bu izolatların *ps1*, *ps2*, *ps3*, *ps4*, *ps5* ve *ps6* parasporin genleri taranmıştır. Literatürdeki çalışmalar *ps* genlerinin Bt izolatlarında görülme oranlarının farklı olduğunu göstermektedir. Aboul-Soud ve ark. (2019) inceledikleri 9 Bt izolatının hepsinin sadece *ps1* geni içerdiğini; Moazamian ve ark. (2018) Bt izolatlarının %43'ünün *ps2*, %20'sinin *ps4* ve %1'inin *ps6* için pozitif olduğunu belirtmişlerdir. Bizim çalışmamızda 19Q2 ve 19Q3 izolatları tüm *ps* genleri için negatif sonuç verirken, BB99 izolatının *ps1* genini içerdiği bulunmuştur. Bu sonuçlara göre BB99 izolatının sitotoksik aktivitesi Parasporin 1 proteininden kaynaklanıyor olabilir. Diğer iki Bt izolatı ise, farklı bir *ps* geni taşıdığı ve henüz ortaya konmadığı için bilinen genlerle sonuç vermemiş olabilir. Parasporin genlerinin sınırlı sayıda tanımlanmış olması, PCR ile parasporin sınıflarının belirlenmesinde bazı kısıtlamalara yol açmaktadır. Literatürde mevcut olan genlerin azlığı nedeniyle, PCR analizinde kullanılan primerler çoğu zaman yalnızca bilinen tek bir gene özgü olarak tasarlanmaktadır. Bu durum, henüz keşfedilmemiş ya da literatürde tanımlanmamış ancak parasporin içeren potansiyel izolatların saptanmasını zorlaştırmaktadır. Dolayısıyla, parasporinlerin tespiti için PCR yöntemi tek başına yeterli değildir. İlerleyen çalışmalarda19Q2 ve 19Q3 izolatlarının sitotoksik aktivitelerine neden olan molekülü tespit etmek için daha detaylı analizler yapılacak ve BB99 izolatının *ps1* geni karakterize edilecektir.

SONUÇ

Bu çalışma ile 6 doğal Bt izolatımızın çeşitli kanser hücre hatları üzerindeki sitotoksik aktiviteleri belirlenmiş ve belirli düzeylerde etkili oldukları görülmüştür. Bu çalışma, doğal anti kanser ilaç geliştirilmesine yönelik ajanların tespiti için önem taşımaktadır. Bunun için bu izolatların apoptotik, anjiyogenik vb. etkileri de araştırılmalı ve detaylı analizlerle anti kanser potansiyeli ortaya konmalıdır.

TEŞEKKÜR

Bu çalışma Muğla Sıtkı Koçman Üniversitesi Bilimsel Araştırma Projesi (BAP) 15/152 numaralı proje kapsamında desteklenmiştir.

Özet

Yangın, karasal ekosistemlerin evrimsel dinamiklerini şekillendiren temel faktörlerden biridir. Yangına adapte olmuş bitki türleri, rekabetin azaldığı yangın sonrası ortamlarda çimlenebilmek için dumanda bulunan kimyasal sinyalleri algılayan moleküler mekanizmalar geliştirmiştir. Bu çalışmada, duman kaynaklı butenolid yapılı sinyal molekülleri olan "Karrikinler" (KARs) kapsamlı bir literatür taraması ile incelenmiştir. Çalışma, karrikinlerin keşif sürecini, kimyasal özelliklerini ve KAI2-MAX2 proteozomal yıkım kompleksine dayalı sinyal iletim mekanizmasını detaylandırmaktadır. Mevcut literatür verileri, karrikinlerin sadece tohum dormansisini kırmakla kalmayıp, aynı zamanda fotomorfogenez, kök mimarisi gelişimi ve kuraklık, tuzluluk gibi abiyotik stres faktörlerine karşı toleransın artırılmasında kritik roller üstlendiğini göstermektedir. Ayrıca, bu moleküllerin tarımsal biyoteknolojideki potansiyel kullanımları; özellikle parazitik yabancı otlarla (*Striga* spp.) mücadelede "intihar çimlenmesi" (suicidal germination) stratejisi ve kültür bitkilerinde verim artışına yönelik tohum "priming" (ön uygulama) teknikleri üzerinden değerlendirilmiştir. Sonuç olarak, karrikinlerin iklim değişikliği ve gıda güvenliği sorunlarına karşı dirençli bitkisel üretim sistemlerinde umut verici bir biyoteknolojik araç olduğu ortaya konmuştur.

Anahtar Kelimeler: Karrikinler, KAI2 reseptörü, Tohum çimlenmesi, Abiyotik stres, İntihar çimlenmesi.

The role of karrikins as plant hormones in plant physiology, their ecological importance and their application potential in agricultural biotechnology.

Abstract

Fire is a fundamental factor shaping the evolutionary dynamics of many terrestrial ecosystems. Fire-adapted plant species have developed molecular mechanisms to perceive chemical signals in smoke to germinate in post-fire environments where competition is reduced. In this study, "Karrikins" (KARs), which are smoke-derived butenolide signaling molecules, are examined through a comprehensive literature review. The study details the discovery process of karrikins, their chemical properties, and the signal transduction mechanism based on the KAI2-MAX2 proteasomal degradation complex. Current literature data indicate that karrikins not only break seed dormancy but also play critical roles in photomorphogenesis, root architecture development, and increasing tolerance to abiotic stress factors such as drought and salinity. Furthermore, the potential uses of these molecules in agricultural biotechnology are evaluated, particularly through the "suicidal germination" strategy for combating parasitic weeds (*Striga* spp.) and seed "priming" techniques for yield enhancement in crops. In conclusion, it is demonstrated that karrikins are a promising biotechnological tool in resilient crop production systems against climate change and food security challenges.

Keywords: Karrikins, KAI2 receptor, Seed germination, Abiotic stress, Suicidal germination.

1.GİRİŞ

Yangın, karasal ekosistemlerin milyonlarca yıldır şekillenmesinde rol oynayan en güçlü evrimsel baskı unsurlarından biridir. Özellikle Akdeniz iklim kuşağı, Güney Afrika'nın Fynbos biyomu, Avustralya'nın çalılık alanları ve Kuzey Amerika'nın chaparral bölgeleri gibi yangına meyilli ekosistemlerde, bitkilerin yaşam döngüsü ateş ile senkronize olmuştur (Dixon et al., 2009). Bu bölgelerdeki bitki örtüsü için yangın, bir

yıkımdan ziyade, rekabetin azaldığı, ışık ve alanın açıldığı, besin maddelerinin (kül yoluyla) toprağa geri döndüğü yeni bir başlangıç fırsatıdır. Ancak bitkilerin bu fırsatı değerlendirebilmesi için tohumlarının doğru zamanda, yani yangın geçtikten hemen sonra çimlenmesi gerekmektedir. İşte bu noktada bitkiler, yangının varlığını algılayabilmek için kimyasal bir "burun" geliştirmişlerdir.

Tarihsel olarak, yerli halklar ve çiftçiler dumanın tohum çimlenmesini artırdığını ampirik olarak biliyorlardı. Ancak bilimsel dünyada bu olgunun sistematik olarak incelenmesi 1990'larda hız kazanmıştır. Başlangıçta ısının veya küldeki minerallerin çimlenmeyi tetiklediği düşünülse de, araştırmalar oda sıcaklığındaki dumanın veya duman emdirilmiş suyun (smoke water) bile çimlenmeyi tetiklediğini göstermiştir (Van Staden et al., 2000). Bu durum, dumanın içinde biyokimyasal bir sinyal molekülü olduğunu kanıtlamıştır. Ancak binlerce bileşen içeren dumanın içinden bu tekil molekülü izole etmek, samanlıkta iğne aramaktan farksızdı. 2004 yılında Batı Avustralya Üniversitesi'nden Gavin Flematti ve ekibinin, selülozun kontrollü yanmasıyla elde edilen duman suyunu hassas kromatografik yöntemlerle (biyo-rehberli fraksiyonasyon) ayrıştırması sonucu, bitki biyolojisinde yeni bir dönem başlamıştır (Flematti, Ghisalberti, Dixon, & Trengove, 2004).

2. KURAMSAL TEMELLER VE LİTERATÜR

2.1. Karrikinlerin Kimyasal Doğası ve Oluşum Mekanizması

Flematti ve ekibinin izole ettiği ve başlangıçta "butenolid" olarak tanımlanan bu molekül sınıfına, Batı Avustralya'nın yerli halkı Noongar'ların dilinde "duman" anlamına gelen "karrik" kelimesinden türetilerek "Karrikin" (KAR) adı verilmiştir (Flematti et al., 2004). Keşfedilen ilk ve biyolojik olarak en aktif molekül KAR1 (3-metil-2H-furo[2,3-c]piran-2-on) olarak isimlendirilmiştir. Daha sonraki çalışmalar, duman içinde KAR1'e yapısal olarak çok benzeyen ancak metil gruplarının konumu veya sayısı bakımından farklılık gösteren KAR2, KAR3, KAR4, KAR5 ve KAR6 gibi analogların da bulunduğunu ortaya koymuştur (Flematti et al., 2007).

Tablo 1: Karrikinlerin Temel Fizikokimyasal Özellikleri

Özellik	**Açıklama**
Kimyasal Sınıf	Furo-piran yapılı Butenolidler
Temel Yapı	Beş üyeli bir butenolid halkasının, altı üyeli bir piran (eter) halkasına füzyonu
Moleküler Formül (KAR1)	$C_8H_6O_3$
Çözünürlük	Suda yüksek çözünürlük (toprak çözeltisinde taşınabilir)
Erime Noktası	118–119 °C
Termal Stabilite	Yüksek sıcaklıklara dayanıklı (yangın kökenli olmasıyla uyumlu)
Fotostabilite	Güneş ışığında (UV) hızla bozunur (yüzeyde birikimi engeller)

Karrikinlerin oluşumu, spesifik bir bitki türüne bağlı değildir; selüloz ve basit şekerler gibi karbonhidratların yanması (piroliz) sonucu oluşurlar (Flematti, Dixon, & Smith, 2015). Bu durum, karrikinlerin evrensel bir "yanmış bitki materyali" sinyali olduğunu gösterir. 180°C gibi nispeten düşük yanma sıcaklıklarında bile 30

dakika içinde oluşabilmeleri, bu moleküllerin doğada neden bu kadar yaygın bulunduğunu açıklamaktadır (Flematti et al., 2015). Yapısal olarak karrikinler, bitkilerde dallanmayı kontrol eden ve parazitik otların çimlenmesini tetikleyen strigolakton (SL) hormonlarına benzerlik gösterirler. Her iki grup da bir butenolid halkası içerir, ancak karrikinler strigolaktonlara kıyasla daha basit, kiral merkezi olmayan ve düzlemsel (planar) bir yapıya sahiptir (Flematti et al., 2015).

2.2. Sinyal İletim Mekanizması: KAI2 Reseptörü ve Evrimsel Paradoks

Karrikinlerin bitki hücresinde nasıl algılandığı sorusu, bilim insanlarını ilginç bir evrimsel paradoksa götürmüştür. *Arabidopsis thaliana* gibi yangına adapte olmamış, hatta yangınla evrimsel geçmişi zayıf olan bitkilerin bile karrikinlere güçlü tepkiler verdiği gözlemlenmiştir (Nelson et al., 2012). Bu durum, karrikinleri algılayan sistemin, aslında bitkinin kendi içinde ürettiği başka bir molekülü algılamak için evrimleştiğini, karrikinlerin ise bu sistemi "taklit ettiğini" düşündürmektedir.

2.2.1. KAI2: Antik Sinyal Alıcısı

Karrikin sinyal yolağının merkezinde **KAI2 (KARRIKIN INSENSITIVE 2)** adı verilen bir reseptör protein bulunur. KAI2, α/β-hidrolaz katlanma yapısına sahip bir enzim-benzeri proteindir (Conn & Nelson, 2015). Bu protein, karrikin molekülünü (veya onun doğal analoğunu) bağladığında şekil değiştirir. KAI2 proteini, bitkiler aleminde son derece korunmuş bir yapıdır; karayosunları (*Physcomitrella patens*) ve ciğer otları (*Marchantia polymorpha*) gibi ilkel kara bitkilerinde bile işlevsel KAI2 homologları bulunmaktadır (Flematti et al., 2015). Bu durum, KAI2 aracılı sinyalizasyonun, tohumlu bitkilerin (Spermatophyta) evriminden çok daha önce, muhtemelen bitkilerin karaya ilk çıkış dönemlerinde ortaya çıktığını göstermektedir.

2.2.2. Sinyal Yolu : MAX2 ve SMAX1

Karrikin sinyalinin hücre çekirdeğinde gen ifadesini değiştirmesi, KAI2'nin tek başına yaptığı bir iş değildir. KAI2, ligandını bağladıktan sonra, **MAX2 (MORE AXILLARY GROWTH 2)** adı verilen bir F-box proteini ile etkileşime girer (Nelson et al., 2012). MAX2, bitki hücresinde bir "çöpçü" gibi çalışan ubikuitin-proteozom sisteminin bir parçasıdır. KAI2-MAX2 kompleksi, hücrede büyümeyi ve çimlenmeyi baskılayan **SMAX1 (SUPPRESSOR OF MAX2 1)** ve benzeri (SMXL2) represör proteinleri hedefler (Stanga, Smith, & Nelson, 2013). Bu hedefleme sonucunda SMAX1 proteinleri yıkıma uğrar. Baskılayıcının ortadan kalkmasıyla (double negative regulation), çimlenmeyi ve fide gelişimini teşvik eden genler aktif hale gelir.

Bu mekanizma, strigolakton (SL) sinyal yolağına (D14-MAX2-SMXL6/7/8) büyük benzerlik gösterir. Her iki yolak da MAX2 proteinini ortak kullanır, ancak farklı reseptörler (KAI2 vs D14) ve farklı hedef represörler (SMAX1 vs SMXL7) sayesinde bitki, karrikin sinyalini strigolakton sinyalinden ayırt edebilir (Conn & Nelson, 2015).

Tablo 2: Karrikin ve Strigolakton Sinyal Yolaklarının Karşılaştırmalı Analizi

Bileşen	**Karrikin (KAR) Yolağı**	**Strigolakton (SL) Yolağı**	**Fonksiyonel Sonuç**
Sinyal Ligandı	Karrikinler (veya KL)	Strigolaktonlar	Sinyalin Başlatılması
Reseptör	KAI2 (AtHTL)	D14 (DWARF14)	Sinyal Algılama
Ortak Bileşen	MAX2 (F-box)	MAX2 (F-box)	Sinyal İletimi
Hedef Represör	SMAX1, SMXL2	SMXL6, SMXL7, SMXL8	Gen Regülasyonu
Biyolojik Çıktı	Çimlenme, Fotomorfogenez, Kök	Dallanma, Parazit Çimlenmesi	Fenotipik Etki

2.3. Karrikinlerin Bitki Fizyolojisindeki Rolleri

Karrikinlerin etkisi, sadece tohumun uyanması ile sınırlı değildir. Bitkinin tüm yaşam döngüsü boyunca, özellikle stres koşullarında ve gelişimsel geçişlerde kritik düzenleyici roller üstlenirler.

2.4. Tohum Dormansisinin Kırılması ve Çimlenme

Karrikinlerin en iyi tanımlanmış rolü, tohum dormansisini (uyku halini) kırmasıdır. Fizyolojik dormansi, tohumun içindeki Absisik Asit (ABA - uykuyu teşvik eden) ve Gibberellin (GA - çimlenmeyi teşvik eden) hormonlarının dengesi ile kontrol edilir. Karrikinler, bu dengeyi GA lehine değiştirirler. *Arabidopsis* üzerinde yapılan çalışmalar, KAR1 uygulamasının GA biyosentez genlerinin (*GA3ox1*, *GA3ox2*) ifadesini artırdığını ve aynı zamanda tohumun GA'ya olan hassasiyetini yükselttiğini göstermiştir (Nelson et al., 2009).

Daha da önemlisi, karrikinler tohumların ışık gereksinimini modüle eder. Birçok bitki tohumu çimlenmek için ışığa ihtiyaç duyar (fotoblastik). Karrikinler, tohumun ışığa olan duyarlılığını artırarak, çok düşük ışık şiddetlerinde bile çimlenmenin gerçekleşmesini sağlar (Nelson et al., 2012). Bu özellik, toprağın derinliklerine gömülmüş veya yoğun bitki örtüsü (gölge) altındaki tohumların, yangın sonrası alan açıldığında hızla çimlenebilmesi için evrimsel bir avantajdır.

2.4.1. Fotomorfogenez ve Fide Gelişimi

Tohum çimlendikten sonra fide, toprağın üzerine çıkıp ışığa ulaştığında gelişim programını değiştirir (skotomorfogenezden fotomorfogeneze geçiş). Karrikin sinyali, bu süreçte fidenin yapısını optimize eder. KAR uygulaması yapılan fidelerde hipokotil (sap) uzaması baskılanır ve kotiledonlar (çenek yaprakları) genişler (Flematti et al., 2015). Bu, fidenin gereksiz yere boya gitmesini engelleyerek enerjisini yaprak gelişimine ve fotosenteze ayırmasını sağlar. SMAX1 mutantlarında (*smax1*) görülen kısa hipokotil ve geniş kotiledon fenotipi, karrikinlerin bu süreçteki baskılayıcıyı (SMAX1) ortadan kaldırarak çalıştığını doğrulamaktadır.

2.4.2. Kök Mimarisi ve Gelişimi

Karrikinler, bitkinin sadece toprak üstü aksamını değil, kök sistemini de etkiler. Lateral (yan) kök oluşumunu ve kök kıllarının yoğunluğunu artırdığına dair bulgular mevcuttur (Flematti et al., 2015). Bu etki, özellikle kuraklık gibi suyun sınırlı olduğu koşullarda bitkinin hayatta kalma şansını artırır.

2.5. Abiyotik Stres Toleransında Karrikinlerin Rolü

Bitkilerin değişen iklim koşullarına adaptasyonunda karrikin sinyal yolağının beklenmedik bir koruyucu rolü olduğu keşfedilmiştir. Bu bulgular, karrikinlerin sadece bir "çimlenme hormonu" olmadığını, genel bir "stres adaptasyon düzenleyicisi" olduğunu göstermektedir.

2.5.1. Kuraklık ve Tuzluluk Stresi

Kuraklık, bitkisel üretimde verimi sınırlayan en önemli faktördür. Araştırmalar, karrikin sinyal yolağındaki SMAX1 proteininin kaybının (yani karrikin sinyalinin aktif olduğu durumun taklidi), bitkilerde kuraklığa karşı toleransı artırdığını göstermiştir (Li et al., 2017). *smax1* mutant bitkilerde yaprak yüzeyinden su kaybının azaldığı ve stoma (gözenek) hareketlerinin daha sıkı kontrol edildiği gözlemlenmiştir. Ayrıca, karrikin uygulaması, bitki hücrelerinde Reaktif Oksijen Türlerini (ROS) temizleyen antioksidan enzimlerin aktivitesini artırarak, tuzluluk ve kuraklığın neden olduğu oksidatif hasarı azaltır. Buğday fidelerinde yapılan bir çalışmada, KAR1 uygulamasının potasyum/sodyum (K+/Na+) dengesini koruyarak tuz stresinin etkilerini hafiflettiği rapor edilmiştir (Shah et al., 2020).

2.5.2. Sıcaklık ve Ozmotik Stres

Yüksek sıcaklıklar ve ozmotik stres altında, karrikin reseptörü KAI2'nin fonksiyonu hayati önem taşır. *kai2* mutantlarının (karrikin algılayamayan bitkiler) yüksek sıcaklıklarda çimlenme yeteneğini kaybettiği ve stres koşullarında fide canlılığının düştüğü belirlenmiştir. KAR1 uygulaması, domates tohumlarının yüksek sıcaklıkta çimlenmesini teşvik ederek termal inhibisyonu (ısıya bağlı çimlenme durması) aşmalarına yardımcı olmaktadır (Jain & Van Staden, 2006).

2.6. Tarımsal ve Ekolojik Uygulama Potansiyelleri

Karrikinlerin temel bilimdeki bu etkileyici özellikleri, tarımsal biyoteknoloji ve ekolojik restorasyon alanlarında somut uygulamalara dönüştürülmeye başlanmıştır.

2.6.1. Yabancı Ot Mücadelesi: "İntihar Çimlenmesi" (Suicidal Germination)

Tarımsal üretimde en büyük maliyet kalemlerinden biri yabancı ot mücadelesidir. Geleneksel yöntemler genellikle bitki çıktıktan sonra müdahaleye dayanır. Ancak karrikinler, "intihar çimlenmesi" adı verilen proaktif bir strateji sunar. Bu yöntemde, tarla henüz ekilmeden önce toprağa karrikin veya duman suyu uygulanır. Bu sinyal, toprak tohum bankasında bekleyen dormant (uykudaki) yabancı ot tohumlarını, mevsimi olmasa veya koşullar tam uygun olmasa bile kitleler halinde çimlenmeye teşvik eder (Flematti et al., 2015).

Çimlenen bu yabancı otlar, henüz kültür bitkisi ekilmediği için mekanik sürümle veya hafif dozda herbisit ile kolayca yok edilebilir. Böylece toprak tohum rezervi tüketilmiş olur. Bu strateji özellikle *Avena fatua* (yabani yulaf), *Brassica tournefortii* ve en önemlisi *Striga* (cadı otu) gibi parazitik otlara karşı denenmektedir (Flematti et al., 2015). *Striga* tohumları normalde konukçu bitkiden salgılanan strigolaktonları bekler; ancak karrikin benzeri sentetik analoglar veya duman türevleri ile bu tohumlar "kandırılarak" konukçu yokken çimlenmeye zorlanabilir, bu da parazitin ölümüne yol açar (suicidal germination).

2.6.2. Tohum "Priming" ve Ürün Verimi

Kültür bitkilerinin tohumlarının ekim öncesi belirli bir süre karrikin çözeltisinde bekletilmesi (priming), çimlenme yüzdesini, çıkış hızını ve fide homojenliğini artırmaktadır.

Domates ve Biber: KAR1 priming işlemi, bu bitkilerin tohumlarının düşük sıcaklıklarda veya tuzlu topraklarda bile yüksek oranda çimlenmesini sağlamaktadır (Jain & Van Staden, 2006).
Tahıllar: Buğday ve mısırda yapılan denemeler, KAR uygulamasının kök kütlesini artırarak bitkinin topraktan besin ve su alım kapasitesini iyileştirdiğini göstermiştir.
Soya Fasulyesi: Karrikinlerin soya tohumlarında hasat öncesi çimlenmeyi (pre-harvest sprouting)

engelleyebileceğine dair çalışmalar mevcuttur; bu, ürün kalitesini korumak adına önemli bir potansiyeldir.

2.6.3. Biyoçar (Biochar) ve Toprak İyileştirme

Biyoçar, organik maddelerin oksijensiz ortamda yakılmasıyla elde edilen ve toprağa karbon bağlamak için kullanılan bir materyaldir. Son analizler, biyoçarın üretim sürecinde doğal olarak karrikinlerin oluştuğunu ve biyoçarın bitki gelişimi üzerindeki olumlu etkilerinin bir kısmının, gözeneklerine hapsolmuş bu karrikinlerden kaynaklandığını ortaya koymuştur (Kochanek et al., 2016).

2.6.4. Ekolojik Restorasyon

Madencilik sonrası bozulan arazilerin veya yangın görmüş alanların rehabilitasyonunda, endemik bitki tohumlarının çimlenmesini sağlamak büyük bir sorundur. Karrikin içeren duman suyu uygulamaları, özellikle Avustralya'da maden sahalarının rehabilitasyonunda, doğal tohum bankasını harekete geçirerek biyoçeşitliliği artırmak amacıyla standart bir prosedür olarak kullanılmaktadır (Dixon et al., 2009).

2.7. Gelecek Perspektifi: Kayıp Halka "KL"

Karrikin araştırmalarındaki en büyük bilimsel boşluk, "KAI2 Ligand" (KL) olarak adlandırılan içsel hormonun kimliğidir. Bitkilerin, yangınla hiç karşılaşmasalar bile KAI2 reseptörünü milyonlarca yıldır korumuş olmaları, bu reseptörün aslında bitkinin kendi ürettiği bir hormonu algılamakla görevli olduğunu kanıtlamaktadır (Conn & Nelson, 2015). Karrikinler, muhtemelen bu gizemli KL hormonunun tesadüfi bir yapısal taklididir. Bilim insanları şu an bu endojen ligandı izole etmeye çalışmaktadır. KL'nin keşfi, bitki gelişimi ve stres yanıtları üzerinde, oksin veya giberellinlerin keşfi kadar büyük bir etki yaratabilir.

3. SONUÇ

Karrikinler, doğanın yıkıcı gücü olan ateşin, yaşamın devamlılığını sağlayan yapıcı bir sinyale nasıl dönüştüğünün en zarif moleküler örneğidir. Keşfedilmelerinden bu yana geçen yirmi yılda, sadece bitki fizyolojisinin karanlıkta kalmış bir köşesini aydınlatmakla kalmamış, aynı zamanda küresel gıda güvenliğini tehdit eden abiyotik stresler ve yabancı otlarla mücadelede güçlü bir biyoteknolojik araç haline gelmişlerdir. Gelecekteki araştırmalar, karrikin sinyal yolağının genetik manipülasyonu ve sentetik analogların geliştirilmesi üzerine yoğunlaşarak, tarımda "akıllı bitkiler" dönemini başlatabilir.

Özet

KBRN (Kimyasal, Biyolojik, Radyolojik ve Nükleer) olayları, insan yaşamında ciddi olumsuz sonuçlar doğuran afetlerdir. Bu tür olaylara karşı hazırlıksız olunması ve önlem alınmaması, zamanla daha büyük riskler yaratmaktadır. Bu nedenle, bireylerin KBRN farkındalık düzeylerinin artırılması ve doğru müdahale bilgilerinin verilmesi büyük önem taşımaktadır. Bu çalışma, KBRN olaylarına yönelik bilgi düzeyinin artırılmasında animasyon teknolojisinin kullanımını incelemektedir. Araştırmada lisans düzeyindeki hemşirelik ve tıp öğrencileri örneklem olarak seçilmiştir. Öğrencilerin KBRN farkındalık ve bilgi düzeyleri, eğitim öncesi ve sonrası yapılan testlerle değerlendirilmiştir. Elde edilen bulgular, animasyon teknolojisiyle desteklenen eğitimin öğrencilerin KBRN konularına ilişkin bilgi düzeylerini istatistiksel olarak anlamlı biçimde artırdığını göstermektedir. Görüş ölçeğinden elde edilen veriler de bu bulguları destekler niteliktedir. Ortalama puanlar incelendiğinde, öğrenciler animasyonların derse ilgilerini artırdığını, konuları anlamalarını kolaylaştırdığını ve öğrenme sürecini daha eğlenceli hâle getirdiğini belirtmişlerdir.

Anahtar Kelimeler: KBRN, Farkındalık, Animasyon, Eğitim

Examination of the Use and Impact of Animation Technology in Increasing CBRN Knowledge: A Case Study of Undergraduate Students at Niğde Ömer Halisdemir University, Faculty of Medicine and Nursing

Abstract

CBRN (Chemical, Biological, Radiological, and Nuclear) incidents are disasters that have serious adverse effects on human life. Lack of preparedness and failure to take preventive measures against such events can lead to increasingly greater risks over time. Therefore, it is of great importance to enhance individuals' awareness of CBRN threats and to provide them with accurate information regarding appropriate response measures. This study examines the use of animation technology in increasing knowledge levels related to CBRN incidents. Undergraduate nursing and medical students were selected as the sample group. The students' levels of CBRN awareness and knowledge were assessed through pre- and post-training tests. The findings indicate that education supported by animation technology significantly increased students' knowledge levels on CBRN topics in a statistically meaningful way. Data obtained from the opinion scale also support these findings. An examination of the mean scores reveals that students reported that animations increased their interest in the course, facilitated their understanding of the subjects, and made the learning process more enjoyable.

Keywords: CBRN, Awarness, Animation, Education

GİRİŞ

KBRN afetlerinin farkındalığının artırılması, olası risklerin en aza indirilmesi, toplumun ve KBRN olaylarına maruz kalabilecek kişilerin bilinçlendirilmesi hayati bir önem taşır. Bu konuda bilinç oluşturmak, KBRN olaylarını yıkıcı etkilerini önlemek ve müdahale süreçlerini iyileştirmek için kritik bir gerekliliktir. (Dönmez, 2019)

Günümüzde hızla gelişen teknoloji, eğitim ve farkındalık oluşturma süreçlerinde yeni yöntemlerin ve araçların kullanımını teşvik etmektedir. Özellikle KBRN gibi karmaşık ve hayati öneme sahip konularda, yeni teknolojilerin sunduğu imkanlar dikkat çekmektedir. İşte tam da bu noktada, animasyon teknolojisi gibi görsel ve interaktif eğitim araçları devreye girmektedir. Animasyonlar, karmaşık kavramları sadeleştirerek, eğitimi daha anlaşılır ve çekici hale getirebilir. Bu tür teknolojik araçlar, öğrenme sürecini hızlandırma açısından önemlidir. Animasyon teknolojisinin eğitim materyallerine dahil edilmesi hem eğitimlerin etkinliğini artırabilir hem de KBRN farkındalığının daha geniş kitlelere ulaşmasını sağlayabilir. (Yeh ve Yang, 2024; Ercan vd., 2014)

Genel olarak yapılan çalışmalarda animasyon ile desteklenen eğitimlerin, bireylerin bilgileri akılda tutma düzeyine, konunun daha anlaşılır hale gelmesine ve akademik başarıların artmasına anlamlı derecede olumlu katkılar sağladığı belirtilmektedir. Bu çalışma, animasyon destekli KBRN eğitimlerinin, Niğde Ömer Halisdemir Üniversitesi tıp ve hemşirelik bölümü öğrencilerinin KBRN bilgi düzeylerini artırma konusundaki etkinliğini incelemeyi amaçlamaktadır.

MATERYAL VE METOT

Animasyonun Hazırlanması

Bu animasyon, kimyasal, biyolojik, radyolojik ve nükleer (KBRN) ajanlara ilişkin farkındalığı artırmak amacıyla hazırlanmıştır. İçeriğin oluşturulmasında akademik çalışmalar ve ilgili bakanlıklar tarafından yayımlanan resmi bilgilendirme materyalleri titizlikle incelenmiştir. Animasyon, KBRN olaylarına karşı toplumun bilinç düzeyini artırmayı ve güvenli davranışların kazandırılmasını hedeflemektedir.

Animasyonun senaryo akışı, izleyicilerin konuyu adım adım kavrayabilmesi esas alınarak tasarlanmıştır. Akış, sırasıyla kimyasal, biyolojik, radyolojik ve nükleer ajanların etkileri, sınıflandırmaları, yayılma yolları ve korunma yöntemleri üzerinde yoğunlaşmaktadır.

Buna ek olarak, animasyonda ülkemizde kullanılan tehlike alarm işaretlerine de yer verilmiş olup, izleyicilerin acil durumlarda alarm seslerini tanıyabilmeleri ve doğru tepkileri verebilmeleri hedeflenmiştir. Böylece, animasyon yalnızca bilgi aktarımı ile sınırlı kalmayıp, izleyicilerin davranışsal olarak da hazırlanmasına katkı sağlamaktadır.

Kapsam ve Yöntem

Bu çalışmada, Niğde Ömer Halisdemir Üniversitesi Tıp ve Hemşirelik Bölümü öğrencilerine animasyon ile KBRN eğitiminin etkinliğini belirlemek amacıyla yarı deneysel bir yöntem kullanılmıştır. Araştırmanın örneklemini, Niğde Ömer Halisdemir Üniversitesi tıp ve hemşirelik bölümünde öğrenim gören 315 lisans öğrencisi oluşturmaktadır.

Katılımcılara öncelikle eğitim öncesi KBRN Bilgi Testi uygulanmış ve ardından animasyon yöntemiyle KBRN eğitimi verilmiştir. Eğitim sonrasında katılımcılara tekrar KBRN Bilgi Testi uygulanmıştır. Katılımcıların animasyonla yapılan eğitime yönelik memnuniyetini ölçmek amacıyla animasyon görüş ölçeği de uygulanmıştır. Animasyon Görüş ölçeğini eğitime katılan öğrencilerden 287 kişi doldurmuştur.

Veri Toplama Araçları

Araştırmada, ölçek geliştirme sürecinde veri toplama aracı olarak iki bölümden oluşan bir test formu kullanılmıştır. Formun birinci bölümünde, katılımcıların okuduğu bölüm, cinsiyet, sınıf ve yaş bilgilerini içeren demografik bilgi formu, ikinci bölümünde ise KBRN Bilgi Testi yer almaktadır.

Kullanılan KBRN Bilgi Testi, her biri beş seçenekten (a, b, c, d, e) oluşan, 20 çoktan seçmeli sorudan meydana gelmektedir. Her soruda yalnızca bir doğru yanıt bulunmaktadır. Katılımcıların verdikleri cevaplar, doğru = 1

ve yanlış = 0 şeklinde puanlanmıştır. Araştırmada, ön test ve son test uygulamaları aynı form ve madde yapısı kullanılarak gerçekleştirilmiştir.

Eğitim sonrasında, eğitimde kullanılan animasyonların içeriğine ilişkin katılımcı görüşlerini tespit etmek için Daşdemir vd. (2012) tarafından geliştirilen Animasyon Görüş Ölçeği kullanılmıştır. Ölçek, beşli Likert tipi bir derecelendirmeye sahiptir (1 = Kesinlikle katılmıyorum, 5 = Kesinlikle katılıyorum) ve toplam 13 maddeden oluşmaktadır. Ölçekten elde edilebilecek puanlar 13 ile 65 arasında değişmektedir.

Veri Analizi

Bu çalışmanın veri analizinde SPSS 31.0.1.0 sürümü ve Microsoft Excel programları kullanılmıştır.

Veri seti, aynı katılımcı grubuna ait ön test (Test 1) ve son test (Test 2) uygulamalarından elde edilmiştir. Ancak, veri toplama formunda kimlik veya kişisel bilgi (ad, numara vb.) yer almadığı için katılımcılar birebir eşleştirilememiştir. Bu nedenle, analizlerde Grup değişkeni altında "1 = Ön test" ve "2 = Son test" kodlaması yapılarak, veriler bağımsız iki grup (eğitim alan grup, eğitim almayan grup) varsayımıyla değerlendirilmiştir.

Her ne kadar istatistiksel analizler bağımsız iki grup yaklaşımıyla yapılmış olsa da veriler aynı grubun iki farklı zamanda yapılan ölçümünü temsil etmektedir. Yarı deneysel desenlerde, bireysel eşleştirmenin mümkün olmadığı durumlarda aynı grubun farklı zamanlarda ölçülmesi yöntemi uygulanabilir. Bu yaklaşım, karşılaştırmalı analizlerde kullanılabilen geçerli bir alternatiftir.

BULGULAR

Tablo 1. Demografik Bilgiler

Değişken	Kategori	Yüzde (%)
Cinsiyet	Kadın	67,0
	Erkek	32,7
	Belirtmek istemiyorum	0,3

Tablo 2. Güvenilirlik Testi

Uygulama Türü	Madde Sayısı	Cronbach's Alpha (α)	Güvenirlik Düzeyi
Ön Test	20	0.561	Düşük
Son Test	20	0.692	Kabul edilebilir

KBRN Bilgi Testi'nin iç tutarlılık güvenirliği Cronbach's Alpha katsayısı ile değerlendirilmiştir. Ön test uygulamasında Cronbach's Alpha değeri $\alpha = 0.561$ olarak bulunmuş; bu değer, eğitim öncesinde öğrencilerin madde yanıtlarının heterojen olduğunu göstermektedir. Son test uygulamasında ise Cronbach's Alpha değeri $\alpha = 0.692$ olarak hesaplanmış ve testin eğitim sonrasında kabul edilebilir düzeyde iç tutarlılığa sahip olduğu belirlenmiştir. Bu sonuçlar, animasyon destekli eğitimin öğrencilerin bilgi düzeyini artmasının yanı sıra maddeler arasındaki yanıt tutarlılığını da güçlendirdiğini ortaya koymaktadır.

Tablo 3. Normallik Testi

Grup	Kolmogorov–Smirnov (KS)	df	P
Test 1 (Ön test)	0,122	315	<0,001
Test 2 (Son test)	0,105	315	<0,001

Her iki grupta da yapılan Kolmogorov–Smirnov (KS) ve Shapiro–Wilk (SW) normallik testlerinde p <0,001 bulunmuştur. Bu sonuç, toplam puanların normal dağılım göstermediğini ortaya koymaktadır. Dolayısıyla, gruplar arası farkın incelenmesinde parametrik olmayan bir yöntem tercih edilmiştir.

Tablo 4. Mann- Whitney U Testi

	Toplam Skor
Mann-Whitney U	11929,000
Wilcoxon W	61699,000
Z	−16,541
Asymp. Sig. (2-tailed)	<,001

Toplam Skor değişkenine ilişkin analizde, Gruplar değişkenine göre yapılan Mann–Whitney U testi sonucunda U = 11929,000, Z = −16,541 ve Asymp. Sig. (2-tailed) <0,001 olarak bulunmuştur. Bu sonuç, ön test ve son test grupları arasında istatistiksel olarak anlamlı bir fark olduğunu göstermektedir. Başka bir ifadeyle, katılımcıların son testteki toplam puanlarının ön test puanlarına göre anlamlı düzeyde daha yüksek olduğu söylenebilir. Bu bulgu, animasyon destekli eğitimin KBRN bilgi düzeyini artırmada etkili olduğunu desteklemektedir.

Tablo 5. Mann- Whitney U Testi Sıra Ortalaması ve Toplamı

Grup	N	Sıra Ortalaması	Sıra Toplamı
Test 1 (Ön test)	315	195,87	61699,00
Test 2 (Son test)	315	435,13	137066,00
Toplam	630		

Mann–Whitney U testi sonuçlarına göre, sıra ortalaması (mean rank) değeri Test 2 için 435,13, Test 1 için ise 195,87 olarak bulunmuştur. Bu bulgu, son test puanlarının genel olarak ön test puanlarından daha yüksek sıralarda yer aldığını göstermektedir. Başka bir ifadeyle, farkın yönü son test lehinedir; yani katılımcıların eğitim sonrasında KBRN bilgi düzeylerinin anlamlı biçimde arttığı söylenebilir.

Tablo 6. Doğru/Yanlış Çapraz Tablosu

Soru	Grup	Yanlış Sayısı	Yanlış (%)	Doğru Sayısı	Doğru (%)
S1	Test 1 (Ön test)	99	31,4	216	68,6
	Test 2 (Son test)	29	9,2	286	90,8
S2	Test 1 (Ön test)	105	33,3	210	66,7
	Test 2 (Son test)	115	36,5	200	63,5
S3	Test 1 (Ön test)	207	65,7	108	34,3
	Test 2 (Son test)	19	6	296	94

	Test 2 (Son test)	207	65,7	108	34,3
S14	Test 1 (Ön test)	164	52,1	151	47,9
	Test 2 (Son test)	129	41	186	59
S15	Test 1 (Ön test)	70	22,2	245	77,8
	Test 2 (Son test)	29	9,2	286	90,8
S16	Test 1 (Ön test)	261	82,9	54	17,1
	Test 2 (Son test)	201	63,8	114	36,2
S17	Test 1 (Ön test)	257	81,6	58	18,4
	Test 2 (Son test)	75	23,8	240	76,2
S18	Test 1 (Ön test)	203	64,4	112	35,6
	Test 2 (Son test)	133	42,2	182	57,8
S19	Test 1 (Ön test)	183	58,1	132	41,9
	Test 2 (Son test)	78	24,8	237	75,2
S20	Test 1 (Ön test)	270	85,7	45	14,3
	Test 2 (Son test)	99	31,4	216	68,6

Tablo 7. Görüş Ölçeği Güvenilirlik Analizi

Ölçek / Test Adı	**Madde Sayısı**	**Cronbach's Alpha**	**Güvenilirlik Düzeyi**
Animasyon Görüş Ölçeği	13	0,861	Güvenilir

Görüş Ölçeği'nin iç tutarlılığı, Cronbach's Alpha katsayısı ile değerlendirilmiştir. Ölçek 13 maddeden oluşmaktadır. SPSS programı ile yapılan analiz sonucunda Cronbach's Alpha (α) = 0,861 olarak bulunmuştur. Bu değer testin "güvenilir" düzeyde iç tutarlılığa sahip olduğunu göstermektedir.

Tablo 8. Görüş Ölçeği Tanımlayıcı İstatistikler

Madde	**Ortalama ($\bar{X}$)**	**Std. Sapma**	**N**
Animasyonlarla işlenen konular daha fazla ilgimi çekti.	4,34	0,759	280
Animasyonlar konuyla ilgili soruları çözmeme yardımcı oldu.	4,44	0,689	282
Animasyonların kullanımı konu hakkında daha ayrıntılı düşünmemi sağladı.	4,33	0,784	285
Animasyonlar diğer derslerde de kullanılmalıdır.	4,46	0,747	280
Animasyonların kullanımı konuya yoğunlaşmamı sağladı.	4,48	0,731	283
Animasyonlarla işlenen konular çok hoşuma gitti.	4,29	0,864	282
Animasyonların kullanımı yaratıcı düşünmeme yardımcı oldu.	4,24	0,862	276
Animasyonlar çok karmaşık olduğundan konuları öğrenemedim.	3,92	1,395	260
Derslerde animasyonların kullanımı çok faydalıdır.	4,31	0,819	281

Animasyonlar dersi daha iyi anlamama yardımcı oldu.	4,39	0,759	285
Animasyonlarla ders işlemek sıkıcıdır.	4,09	1,253	264
Animasyonların kullanımı sınıfta düzensizliğe yol açtı.	4,15	1,216	279
Animasyonların kullanımı işlenen konuların anlaşılmasını zorlaştırdı.	4,27	1,197	281

Elde edilen bulgulara göre, Görüş Ölçeğinin tüm maddelerine ilişkin ortalama puanların 4,09 ile 4,48 aralığında yoğunlaştığı görülmüştür. Bu sonuç, katılımcıların büyük çoğunluğunun animasyon destekli eğitim uygulamalarına olumlu yaklaştığını göstermektedir.

Negatif anlam taşıyan maddelerde (örneğin, "Animasyonlarla ders işlemek sıkıcıdır", "Animasyonların kullanımı sınıfta düzensizliğe yol açtı." vb.) ortalama değerlerin görece yüksek çıkması, bu ifadelerin ters kodlu olduğundan kaynaklanmaktadır. Dolayısıyla, bu maddeler ters çevrilerek yorumlandığında, genel eğilimin yine olumlu yönde olduğu anlaşılmaktadır.

Sonuç olarak, öğrenciler animasyon destekli öğretimin:

- İlgilerini artırdığını,
- Konuya yoğunlaşmalarını sağladığını,
- Karmaşık konuların anlaşılmasını kolaylaştırdığını ifade etmişlerdir.

Bu bulgular, animasyon tabanlı öğretim uygulamalarının öğrenme sürecine ilişkin olumlu görüşlerle karşılandığını ve öğrenciler tarafından etkili, ilgi çekici ve öğrenmeyi destekleyici bir yöntem olarak değerlendirildiğini ortaya koymaktadır.

TARTIŞMA

Araştırma sonuçları, öğrencilerin KBRN konusundaki başlangıç bilgi düzeylerinin düşük olduğunu, ancak animasyon destekli eğitim sonrasında bilgi ve farkındalıklarında belirgin bir artış gerçekleştiğini göstermektedir. Bu bulgu, afet ve KBRN eğitimlerinde teknolojik materyallerin kullanımının öğrenme sürecine önemli katkılar sağladığını ortaya koyan literatürle büyük ölçüde örtüşmektedir.

Mızrak (2018), Özden ve Yaman (2022) ile Avcı (2023) tarafından yürütülen çalışmalarda da afet ve KBRN eğitimlerinin bireylerin bilgi ve farkındalıklarını artırdığı vurgulanmıştır. Bu çalışmalar, eğitimin afet farkındalığını güçlendirdiğini göstermekte olup, mevcut araştırmanın bulgularını desteklemektedir.

Benzer şekilde Murtinger ve arkadaşları (2021), sanal gerçeklik gibi teknoloji tabanlı yöntemlerin KBRN eğitimlerinde etkili olduğunu belirtmiştir. Bu tezde kullanılan animasyon destekli eğitimin de öğrenmeyi daha anlaşılır ve kalıcı hâle getirdiği görülmüş; teknoloji destekli öğretimin KBRN eğitimlerinde önemli bir araç olduğu yönündeki bulgularla uyum göstermiştir.

Gran ve ark. (2024) tarafından simülasyon temelli eğitimle elde edilen olumlu sonuçlar da bu çalışmayla paralellik taşımaktadır. Her iki araştırmada da dijital ve etkileşimli içeriklerin katılımcıların hazırlık ve müdahale becerilerini geliştirdiği ortaya konmuştur.

Son olarak Dökmeci ve Karakuş'un (2025) çalışmasında çocukların animasyon destekli eğitimle KBRN farkındalığının arttığı belirlenmiş; bu durum, mevcut araştırmada üniversite öğrencilerinde gözlenen bilgi artışıyla benzerlik göstermektedir. Böylece animasyon destekli eğitimin hem çocuklarda hem de genç yetişkinlerde etkili bir öğretim yöntemi olduğu anlaşılmaktadır.

Genel olarak, literatürdeki tüm çalışmalar bu araştırmanın bulgularını desteklemekte; teknoloji tabanlı ve görsel içeriklerle zenginleştirilmiş KBRN eğitiminin farkındalık oluşturma ve öğrenmeyi güçlendirmede etkili bir yöntem olduğunu ortaya koymaktadır.

SONUÇ

KBRN tehditleri, sağlık, çevre ve toplum düzeni üzerinde ciddi etkiler oluşturan çok boyutlu risklerdir. Bu nedenle sağlık alanında eğitim gören öğrencilerin KBRN farkındalığına sahip olmaları kritik bir gerekliliktir. Araştırma sonuçları, öğrencilerin KBRN konusundaki başlangıç bilgi düzeylerinin düşük olduğunu

göstermiştir. Animasyon destekli eğitimin uygulanmasıyla birlikte öğrencilerin hem bilgi düzeylerinin hem de yanıt tutarlılıklarının belirgin biçimde arttığı görülmüştür. Bu durum, animasyon tabanlı öğretimin soyut ve karmaşık KBRN içeriklerinin öğrenilmesinde etkili bir araç olduğunu ortaya koymaktadır.

Öğrencilerin animasyonlara ilişkin görüşleri de bu sonucu desteklemiş; animasyonların ilgiyi artırdığı, konuların daha iyi anlaşılmasını sağladığı ve öğrenmeyi kalıcı hâle getirdiği ifade edilmiştir. Bu bulgular, KBRN konularında mevcut eğitim eksikliğini ortaya koyarken, bu eğitimin programlara daha bütüncül biçimde entegre edilmesi gerektiğini göstermektedir.

Öneriler kapsamında, KBRN ve afet farkındalık eğitimlerinin üniversite müfredatına dâhil edilmesi, animasyon, simülasyon ve diğer dijital materyallerle desteklenmesi, VR gibi ileri teknolojilerin eğitim süreçlerine entegre edilmesi ve periyodik tatbikatların düzenlenmesi önerilmektedir. İleride yapılacak araştırmalar için nitel yöntemlerle öğrencilerin öğrenme deneyimlerinin daha derinlemesine incelenmesi ve KBRN eğitimlerinin toplumsal düzeyde farklı yaş gruplarına yaygınlaştırılması önerilmektedir. Ayrıca öğrencilerin yalnızca bilgi testleriyle değil, uygulama becerilerini değerlendiren ölçme araçlarıyla da desteklenmesi, öğrenme çıktılarının daha kapsamlı biçimde değerlendirilmesine katkı sağlayacaktır.

TEŞEKKÜR

Bu çalışma, Niğde Ömer Halisdemir Üniversitesi Bilimsel Araştırma Projeleri Birimi tarafından SAT 2025/9-LÜTEP numaralı proje kapsamında desteklenmiştir. Projeye sağlanan mali ve bilimsel katkılar için Bilimsel Araştırma Projeleri Koordinasyon Birimi'ne teşekkür ederiz. Sağlanan destek, araştırmanın planlanması, yürütülmesi ve sonuçlandırılmasında önemli rol oynamıştır.

Abstract

In this study; the effects of diatomite application at four different doses (0%, 3%, 6%, 12%) to surface soil samples with three different textures (L, CL, C) on some soil properties and aggregate stability were investigated. As a result of the research conducted in the form of incubation experiment under greenhouse conditions; depending on the applied diatomite amounts, an increase occurred in the water holding capacity and EC values of the soils, and a change occurred in the pH values towards the neutral point. Increases occurred at various levels in the aggregate stability values of the soils depending on the application dose and the structure of the soils. The optimum diatomite doses for aggregate stability values were determined as CL 6%, C 12% and L 12%.

Keywords: Diatomite, aggregate stability, physical soil properties, chemical soil properties

Introduction

Conditioners with different origins are used to improve the dynamic properties of the soil for the purposes of use, to create a suitable plant growth environment, to eliminate the problems of the soil, to prevent environmental degradation and to control erosion (Özdemir et al., 2017). The use of some inorganic conditioners such as diatomite for these purposes is quite limited (Dessalew et al., 2017; Oliva et al., 2020).

Diatomite applications; in order to create a structure resistant to erosion by increasing the amount of water-resistant aggregates (Aksakal et al., 2012), soil of plant nutrient content (Prakash et al., 2019; Oliva et al., 2020) and in the positive impact of plant development by increasing the holding capacity (Angin et al., 2011; Boyraz and Nalbant, 2015), reducing soil compaction by reducing volume weight values (Waltz and McCarty, 2005) and surface hardness (Richardson and Karcher, 2001), soil compaction parameters (maximum dry unit weight and optimum moisture content) and resistance to mechanical forces and sensitivity to erosion (Güler, 2025), eliminating heavy metal pollution (Piri et al., 2021), improving soil consistency limits (Qu and Zhao, 2016), protecting the physical, chemical and biological structure of the soil from the harmful effects of freezing-thawing events (Angin et al., 2016) has been determined to be effective.

Research on alternative regulators that can be used to improve soil properties and create a suitable plant growth environment and a structure resistant to erosion continues. In this study, the effects of diatomite, which has limited use in agricultural areas (Dessalew et al., 2017; Oliva et al., 2020), on some soil properties and aggregate stability were examined.

Material and Methods

This research was carried out using surface soil samples taken from Ondokuz Mayıs University, Faculty of Agriculture, Bafra and Campus trial areas (41°21'50.0"N, 36°11'23.2"E; 41°33'36.8"N, 35°51'57.5"E; 41°33'39.9"N, 35°51'57.4"E). The diatomite used was obtained from Beg Tuğ Mineral Company. Some properties of the diatomite used in the experiment are presented in Table 1.

Table1. Some properties of the diatomite used in the experiment

Diatomite properties				
pH, 1:2.5	EC, µS/cm	OM, %	Lime, %	CEC, me/100g
8,35	460.00	0,06	1,20	24,23

The research was conducted as an incubation application under greenhouse conditions using 4.5 kg plastic pots. Diatomite was applied at 0%, 3%, 6%, and 12% (Hemmat et al., 2010; Aksakal et al., 2013) to the soil samples transferred to the pots. The prepared mixtures were left for incubation for 75 days. In this process, irrigation was done again when 50% of the available water in the soil was consumed. After the completion of the process, the soil samples were crumbled by hand and transferred to the laboratory for necessary analyses.

Soil texture was measured by Bouyoucos hydrometer meter (Demiralay, 1993), soil reaction was measured by pH-meter (Kacar, 2016) at 1:2.5 soil-water mixture, electrical conductivity (EC) was measured by EC-meter at 1:2.5 soil-water mixture-meter (Kacar, 2016), lime content Scheibler calcimeter (Kacar, 2016), organic matter content Walkey-Black method (Kacar, 2016), aggregate stability by wet sieving method (Demiralay, 1993), cation exchange capacity by Bower method (Kacar, 2016), exchangeable Na, K, Ca and Mg by ammonium acetate extraction (Kacar, 2016). The SPSS 21.0 package program was used to evaluate the data statistically.

Results and Discussion

Soil properties

Table 2 shows some chemical and physical properties (average) of loam, clayey loam and clay-textured soils used in the study conducted under greenhouse conditions before and after the experiment.

Table 2. Some physical and chemical properties of soils before and after the experiment

	12	7,14	1855,00	1,94	3,40	55,36	24,58	0,80	1,73	82,47		

As can be understood from the evaluation of these data, at the beginning of the experiment, soil sample number 1, taken from the Bafra research and application area, had a loamy texture (L), low alkaline, no salt, low organic matter content and high level of calcareous structure. Soil sample number 2, taken from the Bafra test area, has a clay loam texture (CL), is slightly alkaline, salt-free, has low organic matter content and has a high calcareous structure. Soil sample number 3, taken from the Faculty of Agriculture campus application area, has clayey (C), slightly acid, salt-free, medium organic matter content and low calcareous structure. There are no problems associated with salinity and alkalinity in soils (pH< 8.5) (Kimsey et al., 2020).

It was determined that soil pH (reaction) was affected by diatomite applications. After the incubation period, in parallel with the application levels, there was a decrease towards a neutral point in soils with L and CL textures and an increase towards a neutral point in slightly acid reaction soil with C texture (Table 2). Electrical conductivity values were determined to increase in parallel with the application levels in all three soil groups. Low-level changes occurred in lime and organic matter contents of the soils. The cation exchange capacity and exchangeable Ca, Mg, Na and K contents of the soils increased depending on the diatomite application levels. It was determined that the changes were affected by soil properties (Table 2).

Aggregate stability

The changes in the aggregate stability (AS) values determined in the soils after four different levels of diatomite were applied to loam (L), clay loam (CL) and clay (C) textured surface soil samples and left to incubation under greenhouse conditions are given in Figure 1, and the statistical relationships and analysis of variance results of these values are given in Tables 3 and 4. As seen from the examination of Figure 1, diatomite applied in all three soil groups caused increases in the AS values of the soils. When the increases occurred were examined, the AS value in loamy textured soil number 1 (control) was 43,3% and increased to 58,10 % at the end of the 12% diatomite dose application. A similar change was realized in the clay loam textured soil number 2, and the values increased from 48,6 % to 56,1% at the end of the 12% diatomite dose application. In the clay textured sample number 3 (control), the value increased from 72,4 % to 78,3 % at a 12% diatomite application dose.

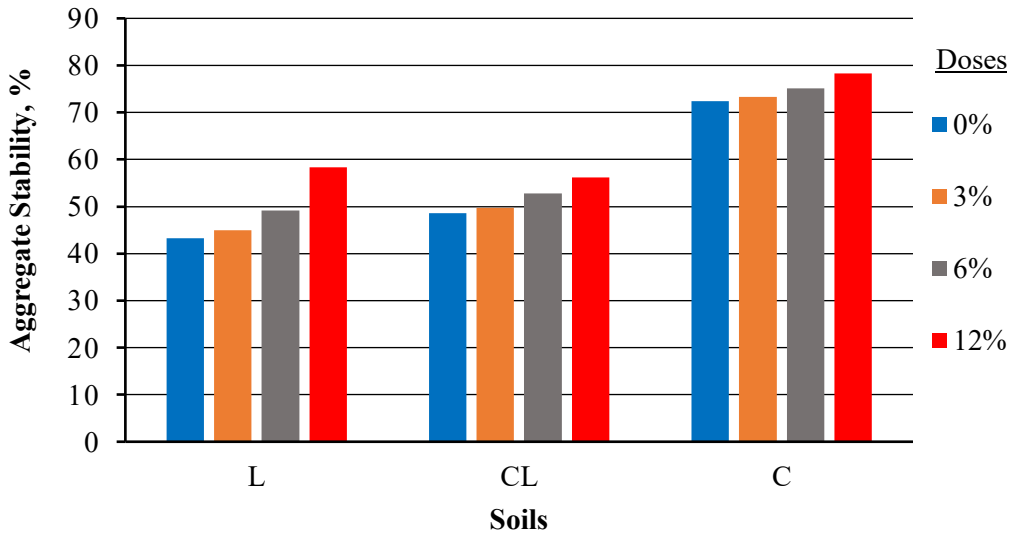

Figure 1. Changes in aggregate stability values depending on the treatments

AS: Aggregate Stability, OM: Organic Matter, Mg: Magnesium, Ca: Calcium, Na: Sodium, K: Potassium, CEC: Cation Exchange Capacity

When the results of the analysis of variance on the effects of diatomite applications on AS value were evaluated (Table 4), it was seen that the effect of the mean squares the soils and the application doses were significant ($p<0.01$).

Table 4. Analysis of variance and Duncan multiple comparison tests for AS values

Source of variation	Degree of freedom	Sum of Squares	Mean Squares	F value	Level of importance
Soils (A)	2	4828,117	2414,059	12540,564	0,000
Doses (B)	3	474,741	158,247	822,062	0,000
AXB	6	85,965	14,327	74,429	0,000
Error	24	4,620	0,193		
Total	36	128535,950			

Averages*			
Soils	L	CL	C
Aggregate Stability	74,775 a	48,866 c	51,816 b

Doses	0%	3%	6%	12%
Aggregate Stability	54,744 d	56,000 c	59,033 b	64,167 a

*: According to Duncan's multiple comparison test, the means indicated with separate letters differ from each other at a 1% level.

When the results of the Duncan multiple comparison test for the source of variation found to be significant were analyzed, the results of the diatomite application of all three soils were different. According to this test, the effectiveness of diatomite application levels differed according to the means of aggregate stability (means with different letters are different from each other according to this multiple comparison test).

While significant negative correlations at 1% level were determined between the aggregate stability values of the soils and sand (-0.789**), silt (-0.526**), lime (-0.884**) data, significant positive correlations at 1% level

were determined between clay (0.773**), organic matter (0.697**), exchangeable magnesium (0.921**), exchangeable potassium (0.906**), cation exchange capacity (0.793**) values of the soils (Table 3).

Aggregate stability values can be used as a good indicator in evaluating the effects of agricultural applications on soil quality parameters and erosion susceptibility. As aggregate stability values increase, quality parameters improve and erosion susceptibility decreases (Özdemir, 2013; Nweke and Nnabude, 2015). When the effects of diatomite applications are examined in this direction, it can be said that diatomite applications increase structural durability and reduce dispersion probability in all three soil groups. When the average proportional changes caused by the applications according to the aggregate stability values of the soils are examined, it is determined that the effectiveness occurs as L (%13.04) > CL (%6.71) > C (%3.27). These findings reveal that diatomite effectiveness decreases as the clay content increases. This situation may be due to the mutual interaction between diatomite and clay content. As a result of their research, Angin et al. (2016) determined that diatomite application reduced bulk density and increased aggregate stability values.

Results

In this study, the effects of diatomite application at four different doses (0%, 3%, 6%, 12%) to soils with three different textures (L, CL, C) on some soil properties and aggregate stability were investigated. The results of the analysis and evaluations can be summarized as follows.

It was determined that pH values in soils decreased towards the neutral point in CL and L textured soils in parallel with the diatomite application dose, and increased towards the neutral point in slightly acidic soil with C texture. Diatomite application increased the EC values of the soils. Low-level changes occurred in the lime and organic matter contents of the soils, and the level of change depended on the initial properties of the soils. Diatomite application caused increases in the amount of water held in the soil, exchangeable cations and cation exchange capacities in parallel with the application doses.

Diatomite application increased the aggregate stability values of the soils. The change that occurred was affected by the soil properties and application dose, and the healing effect of diatomite was more effective in L textured soil. The optimum diatomite doses for aggregate stability values were determined as L 12%, CL 6% and C 12%.

Özet

Bacillus thuringiensis (Bt), sporulasyon sırasında oluşturduğu parasporal kristaller ve içerdiği Cry proteinleri nedeniyle tarım ve halk sağlığında yaygın kullanılan önemli bir biyoinsektisittir. Son yıllarda Bt suşlarının insektisidal olmayan ancak seçici antikanser aktiviteye sahip parasporin proteinleri üretmesi, bu bakteriyi terapötik açıdan dikkat çekici hale getirmiştir. Parasporinler, normal hücrelere zarar vermeden çeşitli kanser hücre hatlarında sitotoksisite oluşturmakta olup, yeni biyoterapötik adaylar arasında gösterilmektedir. Bu çalışmada toprak örneklerinden izole edilen Bt 5.4 izolatının PC-3 prostat kanseri hücre hattı üzerindeki sitotoksik ve anti-migrasyon etkileri değerlendirilmiştir. Öncelikle parasporal protein eldesi gerçekleştirilmiş ve PC-3 hücrelerinde MTT analiziyle sitotoksik etkiler belirlenmiştir. Farklı dozlarda uygulama sonrası 48 saatlik inkübasyon sonucunda izolatın IC_{50} değeri hesaplanmış, cisplatin pozitif kontrol olarak kullanılmıştır. Hücre göçü üzerindeki etkinin değerlendirilmesi amacıyla in vitro yara iyileşme (wound healing) deneyi uygulanmıştır. 0, 4, 10, 24 ve 48. saatlerde elde edilen görüntüler ImageJ yazılımı ile analiz edilerek yara kapanma yüzdeleri hesaplanmıştır. Kontrol grubunda yaranın zamanla belirgin şekilde daraldığı ve 48. saatte yaklaşık %59,3 kapanma görüldüğü saptanmıştır. Buna karşılık Bt 5.4 parasporal proteini uygulanan hücrelerde yara kapanması belirgin biçimde baskılanmış ve 48. saatte yalnızca %24,4 oranında kapanma gerçekleşmiştir. İstatistiksel analizlerde zaman × tedavi etkileşimi anlamlı bulunmuştur ($p = 0.0039$). Bu bulgular, Bt 5.4 izolatına ait parasporal proteinin PC-3 hücrelerinin hem yaşamını azaltarak sitotoksisite oluşturduğunu hem de hücre göçünü inhibe ettiğini göstermektedir. Sonuçlar, Bt parasporal proteinlerinin metastaz hedefli yeni biyoterapötik yaklaşımlar için potansiyel aday olabileceğini ortaya koymaktadır.

Anahtar kelimeler: *Bacillus thuringiensis*, Parasporin, PC-3 prostate kanseri hücre hattı, sitotoksik aktivite, Wound healing assay

Investigation of the cytotoxic and migration-ınhibitory effects of a parasporal protein derived from a natural *Bacillus thuringiensis* ısolate on PC-3 cells

Abstract

Bacillus thuringiensis (Bt) is a Gram-positive, spore-forming bacterium widely used in agriculture and public health due to its parasporal crystals produced during sporulation, which mainly contain insecticidal Cry proteins. In recent years, several Bt strains have been shown to synthesize parasporins—non-insecticidal proteins that selectively exhibit cytotoxic effects on human cancer cells without harming normal cells—positioning Bt as a promising source of novel biotherapeutic molecules. In this study, the cytotoxic and anti-migratory effects of parasporal proteins obtained from the soil-isolated Bt strain 5.4 were evaluated on PC-3 human prostate cancer cells. Parasporal protein extraction was performed, and cytotoxicity was assessed using the MTT assay. Following treatment with different concentrations of the protein for 48 hours, the IC_{50} value was calculated using cisplatin as a positive control. To investigate the potential inhibitory effect on cell migration, an in vitro wound healing assay was conducted. Images captured at 0, 4, 10, 24, and 48 hours were analyzed using the ImageJ software to determine wound closure percentages. In the control group, the wound area progressively decreased, reaching approximately 59.3% closure at 48 hours. In contrast, cells treated with Bt 5.4 parasporal protein displayed markedly reduced wound closure, achieving only 24.4% closure at the same time point. Statistical analysis revealed a significant

interaction between time and treatment ($p = 0.0039$), indicating that the inhibitory effect on migration increased over time. Overall, these findings demonstrate that parasporal proteins derived from Bt strain 5.4 exert both cytotoxic and migration-inhibitory effects on PC-3 cells. This study suggests that Bt-derived parasporal proteins may represent promising candidates for future metastasis-targeted biotherapeutic applications.

Keywords: Bacillus thuringiensis, Parasporin, PC-3 prostate cancer cells, Cytotoxic activity, Wound healing assay

GİRİŞ

Bacillus thuringiensis (Bt), Gram-pozitif, aerob ve spor oluşturan bir bakteri olup sporulasyon sırasında ayırt edici özelliği olan parasporal kristaller üretir (Li ve ark., 2024;; Lenina ve ark., 2013). Bu kristaller çoğunlukla böceklere özgü δ-endotoksinler olan Cry proteinlerini içerir. Cry proteinler, Lepidoptera, Diptera ve Coleoptera başta olmak üzere birçok böcek grubuna karşı yüksek toksisite gösterdiğinden dolayı (Lenina ve ark., 2013) tarım ve halk sağlığında yaygın kullanılan temel biyoinsektisitlerden biridir. Bt suşları ayrıca chitinazlar, proteazlar, vegetatif insektisit proteinleri (Vip), bakteriyosinler ve özellikle terapötik açıdan dikkat çeken parasporinler gibi çeşitli biyolojik aktif moleküller de sentezlemektedir (Juárez-Hernández ve ark., 2017).

Parasporinler, insektisidal aktivite göstermeyen Bt suşlarının ürettiği, ancak seçici olarak insan kanser hücrelerine etki eden sitotoksik proteinlerdir. Parasporin kavramı ilk olarak Mizuki ve arkadaşları tarafından tanımlanmış olup, normal hücrelere karşı toksik olmayan ve hemolitik aktivite göstermeyen özgün bir biyolojik profil sunmaktadır (Okumura ve ark., 2011; Wong ve ark., 2010; Akiba ve ark., 2009). Günümüzde PS1–PS6 olmak üzere altı parasporin ailesi tanımlanmış olup, her biri çeşitli kanser hücre hatları üzerinde farklı mekanizmalara sahiptir (Okumura ve ark., 2011; Kitada ve ark., 2009; Brasseur ve ark., 2015). Parasporinlerin HepG2, Caco-2, HeLa, MOLT-4, Jurkat ve CEM-SS gibi birçok kanser hücre hattında güçlü sitotoksisite neden olduğu kanıtlanmıştır (Wong ve ark., 2010; Rendon-Marin ve ark., 2021). Mekanizmaları parasporin ailesine göre değişmekle birlikte membran por oluşumu, iyon dengesinin bozulması, kaspaz aracılı hücre ölümü veya reseptör-bağımlı sinyalleşme yollarının aktivasyonu gibi süreçleri içermektedir. Seçici antikanser etkilerinden dolayı parasporinler, son yıllarda yeni nesil biyoterapötik adaylar arasında yer almaktadır.

Bu çalışmada toprak örneklerinden izole edilen 5.4 Bt izolatının, PC-3 (Prostat kanseri hücre hattı) üzerinde sitotoksik etkisi belirlenmiş olup; hücreler üzerinde yapay olarak oluşturulan yara üzerinde hücre göçünü inhibe edip etmediği farklı zaman dilimlerinde yapılan ölçümlerle incelenmiştir. Farklı ekosistemlerden izole edilen Bt suşlarının parasporin gen içeriklerinin belirlenmesi, yeni toksisite profillerinin tanımlanması ve biyoteknolojik uygulamalar için yeni moleküllerin keşfedilmesi açısından önemli bir araştırma alanı oluşturmaktadır.

MATERYAL VE METOT

Bakteri izolatları

Bu çalışmada Muğla Sıtkı Koçman Üniversitesi 15/152 BAP projesi kapsamında gerçekleştirilen doktora tez çalışmasında izole edilen Bt 5.4 izolatı kullanılmıştır (Kesik Oktay, 2019. İzolasyon toprak örneklerinden Santana vd. (2008)' e göre gerçekleştirilmiştir.

Sitotoksik aktivitenin belirlenmesi

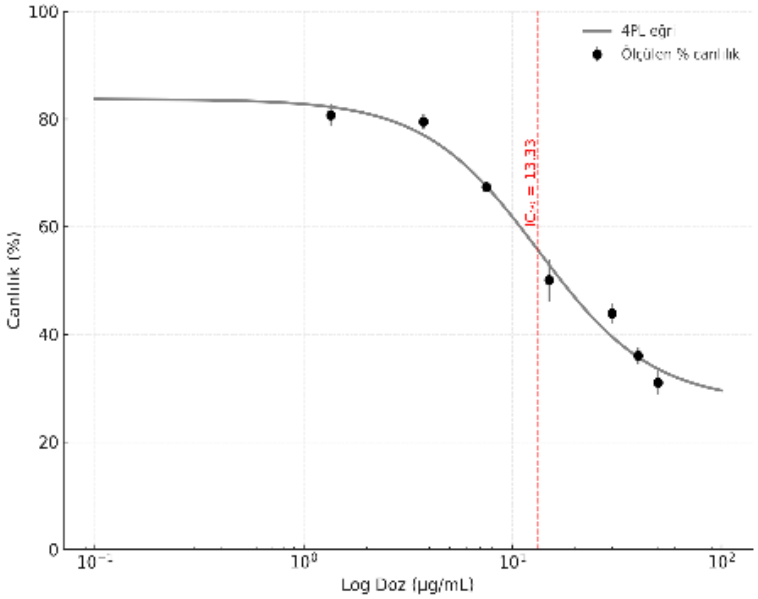
Bu çalışmada PC-3(Prostat kanseri) hücre hattı kullanılmış olup, hücreler % 10 fetal bovin serum ve 100 µg/ml penisilin/streptomisin içeren RPMI 1640 besi ortamında, 37°C'de %5 CO2, %95 hava içeren nemlendirilmiş inkübatörde kültüre alınmışlardır.

Sitotoksik aktivite MTT testi ile değerlendirilmiştir. Bu test, metabolik olarak aktif hücrelerin MTT'yi mor renkli formazan kristallerine indirgemesine dayanır. Bu amaçla, hücreler, 96 kuyulu plaklarda 2×10^4 hücre/kuyu yoğunluğunda 90 µL hücre süspansiyonu ile ekilerek 16–20 saat boyunca 37°C, %5 CO_2 ve %98 nem koşullarında inkübe edilmiştir. Ardından, aktif haldeki Bt 5.4 parasporal kristal proteinleri ilgili konsantrasyonlarda her bir kuyuya eklenmiştir ve plakalar 24–48 saat inkübasyona bırakılmıştır. İnkübasyon sonunda besi ortamı uzaklaştırılarak, her kuyuya 100 µL taze besi ortamı eklenmiştir. Her kuyuya 1:10 oranında MTT stok çözeltisi (5 mg/mL) ilave edilerek plakalar 4 saat inkübe edilmiştir. Ardından 100 µL DMSO eklenerek kristaller çözülmüş ve plakalar 150 rpm hızda 5 dakika çalkalanmıştır. Optik yoğunluk ölçümleri 540 nm (690 nm referans) dalga boylarında bir mikroplaka okuyucu ile gerçekleştirilmiştir (Mikroplate reader, Thermo Fisher Scientific, ABD).

Wound healing assay

Subkonfluent durumda bulunan hücreler pasajlanarak 24 kuyulu hücre kültürü plaklarına her kuyuya 1×10^5 hücre gelecek şekilde inokule edilmiştir. Hücrelerin yüzeye tutunup homojen bir tabaka oluşturması için plateler 37°C, %5 CO_2 ve yüksek nem içeren inkübatörde 20–24 saat bekletilmiştir. İnkübasyon sonrasında, her kuyunun orta hattı boyunca 200 µL'lik pipet ucu kullanılarak düz bir çizik oluşturulmuş ve böylece standart bir yara alanı elde edilmiştir. Çizik sonrası hücre artıkları ve askıda kalan hücreler uzaklaştırılmak üzere kuyular PBS ile iki kez yıkanmıştır. parasporal protein süspansiyonu kuyulara eklenmiştir (Rodriguez ve ark., 2005). Hücre göçü, çizik hattı boyunca gerçekleşen kapanmanın izlenmesiyle değerlendirilmiştir. 4, 12, 24 ve 48. saatlerde plakalar inverted mikroskop altında görüntülenmiştir. Elde edilen görüntüler, çizik kenarına doğru ilerleyen hücrelerin miktarını ve kapanma hızını karşılaştırmak amacıyla kaydedilmiştir. Hücrelerin boşluğa doğru hareketi takip edilerek yara iyileşmesi (wound closure) ve hücre göç dinamikleri belirlenmiştir.

İnkübasyon süresi boyunca hücre göçü, çizik ile oluşturulan boşluk boyunca 0, 4, 24 ve 48. saatlerde inverted mikroskop (10× büyütme) altında izlenmiş ve fotoğraflanmıştır. Elde edilen görüntüler, yara alanının kantitatif ölçümü amacıyla ImageJ yazılımı (http://rsb.info.nih.gov) kullanılarak analiz edilmiştir. Her zaman noktasında çizik bölgesinin alanı ölçülmüş, hücre göçü ve kapanma düzeyi yara kapanma yüzdesi (wound closure %) WC%=[a0−aΔa0]×100 formülü ile hesaplanmıştır.



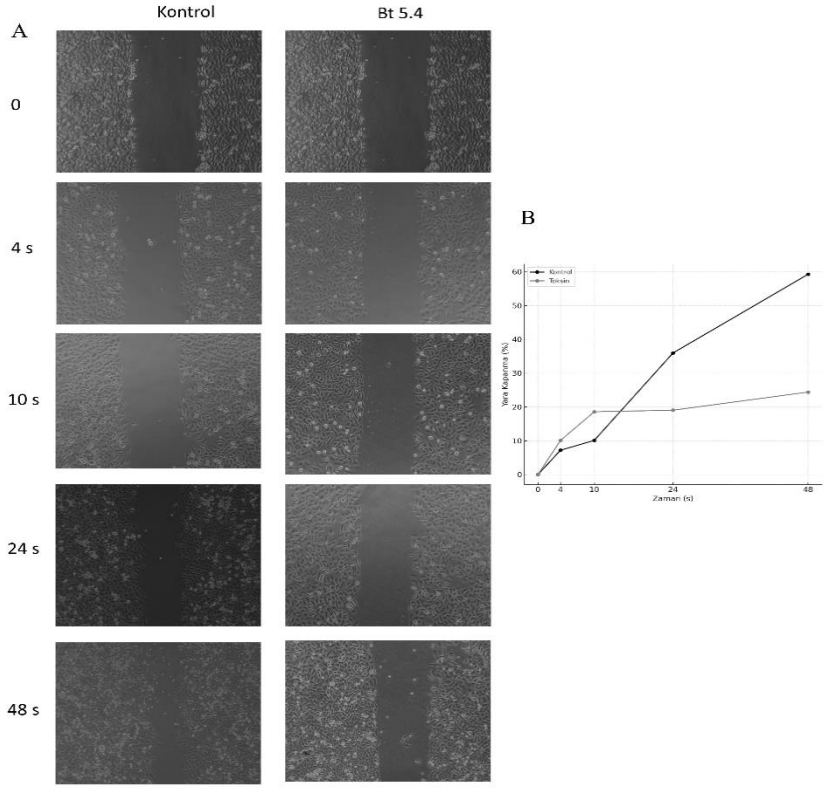
İstatistiksel analizler

Tüm analizlerde GraphPad Prism 8.0.2 programı kullanılmıştır. Sitotoksisite deneyleri sonucunda uygulamalar arasında fark olup olmadığı, tek yönlü varyans analizi (ANOVA) ile değerlendirilmiştir. Uygulamaların kıyaslanmasında Dunnett ve TUKEY HSD testleri kullanılmıştır.

BULGULAR

Sitotoksik aktivitenin belirlenmesi

Bt 5.4 izolatından parasporal pprotein eldesi gerçekleştirilmesinin ardından PC-3 hücre hattı üzerinde farklı konsantrasyonlarda sitotoksik aktivitesi incelenmiştir. 48 saat inkübasyon sonrasında Bt 5.4 izolatının IC_{50} değeri belirlenmiştir. Çalışmalar gerçekleştirilirken pozitif kontrol olarak cisplatin kullanılmıştır.



Şekil 1: Bt 5.4 parasporal proteinine ait IC_{50} değeri. 1.35, 3.75, 7.5, 15, 30, 40 ve 50 µg/ml dozlar kullanılmıştır. Veriler üç tekrarlı olarak gerçekleştirilen deneylerin ortalama değerleridir.

Wound healing assay

PC-3 hücreleri kullanılarak yara iyileşme deneyi gerçekleştirilmiştir. İnverted mikroskop altında görüntüler; 0 (başlangıç), 4, 10, 24 ve 48 saat aralıklarla kaydedilmiştir (10×). Çizik (wound) alanı ImageJ programı kullanılarak ölçülmüş ve yara kapanma yüzdesi başlangıç genişliği referans alınarak hesaplanmıştır. Kontrol grubunda yara bölgesi zaman içinde belirgin şekilde daralmıştır. Yara kapanmasının özellikle 10–24. saat

arasında hızlandığı ve 48. Saatte %59.3 yara kapanma oranı görülmüştür.Toksin uygulanan hücrelerde yara kapanması belirgin şekilde daha yavaştır. Yara genişliği zaman içinde azalsa da 48. saatte yalnızca %24.4 kapanma gözlenmiştir. 24 ve 48. saatlerde kontrol grubuna kıyasla kapanma oranı ciddi düzeyde daha düşüktür. Kontrol grubunda kapanma zamanla belirgin şekilde artarken, toksin uygulamasında yara kapanma hızı belirgin olarak azalmıştır. Zaman × tedavi etkileşimi istatistiksel olarak anlamlı bulunmuştur ($p = 0.0039$), bu da toksinin hücre göçünü zamanla giderek daha fazla inhibe ettiğini göstermektedir.

Şekil 2: A) PC-3 hücreleri üzerinde yara iyileşmesi deneyi sonuçları. Kontrol ve 5.4 izolatına ait parasporal proteinlerin uygulandığı PC-3 hücreleri 0,4, 10, 24, ve 48. saatlerde görüntülenmiştir.
B**)** Kontrol ve toksin uygulanan hücrelerde zaman içinde gözlenen yara kapanma (%) değişimi.

TARTIŞMA

Hücre göçü, gerek fizyolojik süreçlerde gerekse patolojik durumlarda temel bir biyolojik olay olup, yara iyileşmesi, embriyonik gelişim, immün yanıt ve özellikle kanser metastazında kritik bir rol oynamaktadır. Literatürde normal ve tümör hücrelerinin hareketliliğinin, hücrelerin polarizasyonuyla başlayan ve pseudopod oluşumu, aktin filamentlerinin yeniden düzenlenmesi ve hücre dışı matriks (ECM) ile dinamik bağlantıların kurulmasını içeren karmaşık bir mekanizma ile gerçekleştiği iyi bilinmektedir (Keren ve Herber, 2011). Bu süreçte hücre, ileri doğru uzanarak ECM'e tutunmakta ve arka kısmının kasılmasıyla yönlü bir hareket oluşturmaktadır. Dolayısıyla aktin dinamiği ve hücresel çıkıntı oluşumu, göçün başlatılması ve sürdürülmesi için zorunludur.

Son yıllarda çeşitli doğal bileşiklerin ve mikrobiyal ürünlerin kanser hücrelerinde migrasyonu baskıladığına ilişkin çalışmalar artmıştır. Luo ve ark. (2014) tarafından *Lysinibacillus sphaericus* toksinlerinin A549 hücrelerinin hareketliliğini azalttığı; Direito ve ark. (2019) tarafından mentol ekstraktının HT-29 hücrelerinde benzer şekilde göçü engellediği bildirilmiştir. Ayrıca Coriandrum sativum ekstraktının PC-3 hücrelerinde (Elmas ve ark., 2018), miR-154'ün melanoma hücrelerinde (Wang ve ark., 2019), Brucea javanica yağının özofajiyal kanser hücrelerinde (Qiu ve ark., 2019) ve *Sempervivum tectorum* ekstraktının HCT116 hücrelerinde (Cattaneo ve ark., 2019) migrasyon karşıtı etkiler oluşturduğu gösterilmiştir. Ancak literatür incelendiğinde, *Bacillus thuringiensis*'e ait parasporal proteinlerin yara iyileşmesi veya kanser hücre göçü üzerindeki etkilerine dair herhangi bir çalışmanın bulunmadığı dikkat çekmektedir. Bu durum, elde edilen bulguların özgünlüğünü ve literatüre katkı potansiyelini artırmaktadır.

Bu çalışmada 5.4 *B. thuringiensis* izolatından elde edilen parasporal proteinin PC-3 hücrelerinin hareketliliği üzerindeki etkisi yara iyileşme deneyi ile değerlendirilmiştir. Kontrol grubunda yaranın zamanla düzenli

biçimde kapandığı gözlenmiş, bu durum PC-3 hücrelerinin doğal migrasyon kapasitesiyle uyumlu bulunmuştur. Buna karşın parasporal protein uygulanan deney grubunda yaranın kapanmaması, hücrelerin çizik bölgesine doğru yönelim göstermediğini ve göçün belirgin şekilde baskılandığını ortaya koymuştur. Bu etkinin, aktin filament organizasyonu, hücre polarizasyonu veya hücre–ECM etkileşimlerinin bozulması gibi mekanizmalardan kaynaklanabileceği düşünülmektedir. Benzer şekilde diğer migrasyon baskılayıcı doğal bileşiklerin aktin dinamiğinde bozulma, fokal adhezyonların zayıflatılması veya hücre iskeletinin yeniden şekillenmesinin engellenmesi gibi yollarla etki gösterdiği literatürde bildirilmektedir. Bu çalışmanın sonuçları, 5.4 izolatına ait parasporal proteinin PC-3 hücrelerinin göçünü anlamlı düzeyde azalttığını göstermekte ve *B. thuringiensis* kaynaklı proteinlerin kanser hücresi migrasyonunu hedef alan yeni potansiyel biyolojik ajanlar olabileceğini düşündürmektedir. Bu bulgular, özellikle metastaz odaklı antikanser stratejiler açısından önem taşımaktadır. Bununla birlikte, bu etkinin moleküler mekanizmasını anlamak için aktin polimerizasyonu, Rho GTPaz aktivitesi, fokal adhezyon kompleksi proteinleri (örneğin FAK, paxillin) ve ECM etkileşimlerine yönelik ileri analizlerin yapılması gerekmektedir.

Sonuç olarak, bu çalışma *B. thuringiensis* parasporal proteinlerinin ilk kez prostat kanseri hücrelerinin migrasyonunu inhibe edebileceğini göstermektedir. Genişletilmiş in vitro çalışmalar ve farklı kanser hücre hatlarıyla yapılacak analizler, bu proteinlerin potansiyel terapötik etkilerinin anlaşılmasına önemli katkı sağlayacaktır.

Abstract

The proposed voltammetric technique exhibited an excellent linear response on a pretreated pencil graphite electrode (p-PGE) surface in 0.5 M HCl within the 0.02-3.00 µM Brilliant Blue (BB) concentration range. The limit of detection (LOD) for the method in 0.5 M HCl was determined to be 8.50 nM BB. Furthermore, the developed approach was successfully applied to energy drink samples. The results showed good agreement with those obtained by the spectrophotometric method, confirming the reliability of the proposed voltammetric procedure.

Keywords: Brilliant blue, voltammetric determination, energy drink, activated pencil graphite electrode

INTRODUCTION

Artificial colorants are widely incorporated into various food products, including candies, coated tablets, instant drink powders, jellies, desserts, fortified energy beverages, ice creams, and gelatin-containing foods (Karaboduk, 2025). The contamination of aquatic ecosystems by industrial discharges containing synthetic dyes represents a primary global environmental concern. Triarylmethane-based dyes, known for their intense coloration and extensive industrial applications, are particularly resistant to traditional wastewater treatment processes (Thakar et al., 2025). Brilliant Blue (BB) ($C_{37}H_{34}N_2Na_2O_9S_3$; molecular weight: 792.86; E133) as a triarylmethane-based dye is utilized as an industrial-grade colorant in various applications, including toilet cleaning agents, paper dyeing, inks, and markers, as well as in the formulation of cakes, pet foods, powdered beverages, and pharmaceutical products (Jadhav & Gogate, 2025). Its use in food formulations is authorized in the United States and the European Union, with established acceptable daily intake (ADI) limits of 2.5 mg/kg and 5 mg/kg body weight, respectively (Fang et al., 2025).

Various analytical techniques have been employed for the determination of BB, including chromatography (Faraji et al., 2017), spectrophotometry (Olgun et al., 2024), and colorimetry (Özgen et al., 2025). Although these conventional analytical approaches exhibit high sensitivity and selectivity, their practical applicability is often constrained by several drawbacks, including the need for costly instrumentation, labor-intensive and time-consuming sample preparation and analysis procedures, the requirement for skilled operators, and the extensive use of organic solvents (Karaboduk & Karaboduk, 2025). In recent years, electrochemical techniques have emerged as promising alternatives owing to their cost-effectiveness, excellent sensitivity and selectivity, as well as their reliable and reproducible analytical performance (Karaboduk, 2021b). However, several studies have also introduced electrochemical approaches for the quantitative analysis of BB, such as an anodically pretreated boron-doped diamond (BDD) electrode (Medeiros et al., 2012), a novel type of carbon black-polyethylene composite electrode (Lipskikh et al., 2020), a single-monomer dual templated MIP-based electrochemical sensor (George et al., 2024), and a molybdenum disulfide/poly vinylpyrrolidone coated glassy carbon electrode (MoS_2/PVP/GCE) (Murali & Saraswathyamma, 2025).

Pencil graphite electrodes (PGEs), primarily consisting of graphitic carbon blended with clay and polymeric binders, represent an inexpensive and easily accessible electrode material, making them highly suitable for the development of electrochemical sensing platforms (Dang et al., 2025; Van Dat et al., 2025). Pretreatment in voltammetry ensures that the electrode surface is clean, active, and suitable for sensitive and reliable electrochemical measurements. Following pretreatment, an increase in the electroactive surface area of the pencil graphite electrode was observed, enabling the detection of lower analyte concentrations (Rana et al., 2018).

In the present work, a straightforward, easily prepared, and reusable pretreated pencil graphite electrode (p-PGE) was developed and successfully applied for the electrochemical detection of BB in 0.5 M HCl. Compared to the conventional PGE, the p-PGE exhibited significantly enhanced electrochemical response toward BB. Finally, the practical applicability of the p-PGE was evaluated in real sample analyses for BB, and the results were found to be in good agreement with those obtained using UV-Vis spectrophotometry.

MATERIALS AND METHODS

Apparatus and Chemicals

The voltammetric experiments (cyclic voltammetry (CV)) with both pretreated and unpretreated pencil graphite electrodes were performed using a PalmSens 3 potentiostat/galvanostat, controlled with the PSTrace 5.11.1006.19013 software. Disposable pencil-graphite electrodes (PGE, Micro, 2.00 mm, 2B) were obtained from a local stationery supplier in Ankara, Türkiye (Istanbul, Türkiye). The 2B-grade pencil lead used as the electrode consists mainly of graphite (approximately 74%) and clay (about 24%), while the remaining ~2% is a non-electroactive polymer that serves as a binding material. A comprehensive characterization of the pencil graphite electrode was reported in an earlier publication and is not repeated here. (Karaboduk, 2021a). The pH values were determined using a Sartorius Docu-pH+ meter (Göttingen, Germany). All experiments were performed at ambient laboratory temperature. Solutions were prepared with ultrapure water (18.2 MΩ·cm) generated by a BluLab BluAquaT3 purification system (12,051 Alba (CN), Italy). UV–Vis analyses were conducted with a Shimadzu UV-1700 PharmaSpec spectrophotometer (Japan). Brilliant Blue FCF (analytical standard), glucose, fructose, tartrazine, and citric acid from Merck (Darmstadt, Germany) were used. Ascorbic acid was purchased from Sigma Aldrich Co. (St. Louis, MO, USA). All reagents were utilized in their supplied form, with no additional purification steps applied.

Electrode preparation

The outer section of the PGE was insulated with Teflon tape. The working surface of the electrode was polished using P-320 sandpaper and then carefully washed with distilled water. The electrical connection was provided by attaching a copper wire. The PGE was electrochemically activated by cycling the potential between 1.5 and 2.0 V for 50 repetitions in a 0.10 M phosphate buffer at pH 7.0, using a scan rate of 50 mV/s (Karaboduk, 2021a).

RESULTS

Electrochemical Response of Brilliant Blue at Unpretreated/Pretreated Pencil Graphite Electrodes

Cyclic voltammetry was employed to evaluate the electrochemical behavior of both untreated and pretreated PGEs, with 1.0 µM Brilliant Blue (BB) in 0.5 M HCl, as illustrated in Figure 1. The p-PGE enhanced the oxidation peak current of BB, exhibiting clear electrocatalytic activity, with the peak current increasing by approximately 2.1-fold and the oxidation peak potential shifting from 0.809 V to 0.839 V compared to the unpretreated PGE. Additionally, reduction peaks of BB were observed at approximately 0.520 V and 0.530 V on the surfaces of PGE and p-PGE, respectively.

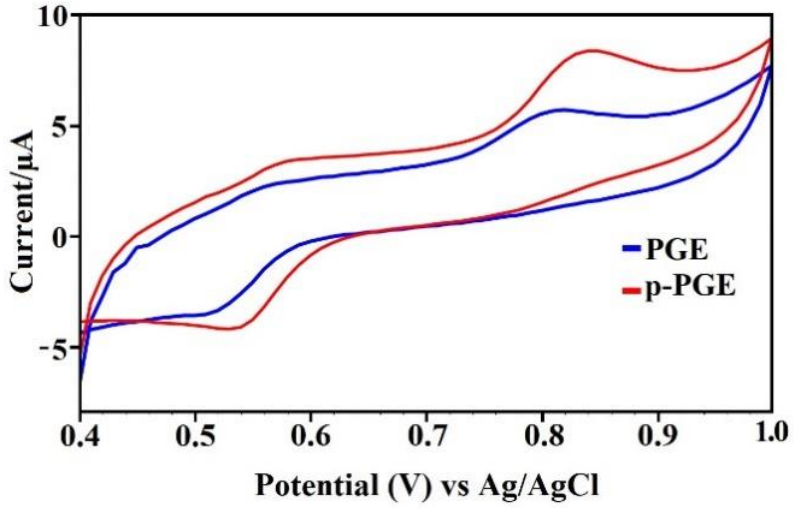

Figure 1. Comparison of the electrochemical behavior of 1.0 µM BB on PGE and p-PGE surfaces in 0.5 M HCl, scan rate:150 mV/s

Effect of Scan Rate

The variation of the redox peak currents with respect to scan rate was examined by performing cyclic voltammetry on BB at scan rates ranging from 10 to 250 mV/s. CV responses of the p-PGE were collected in 0.5 M HCl containing 1.0 µM BB, as shown in Figure 2A. As depicted in Figure 2B, both anodic and cathodic peak currents rise proportionally with the square root of the scan rate. This linear relationship suggests that the electrochemical behavior of BB at the PGE is primarily governed by a diffusion-controlled mechanism (Nejad & Beitollahi, 2025).

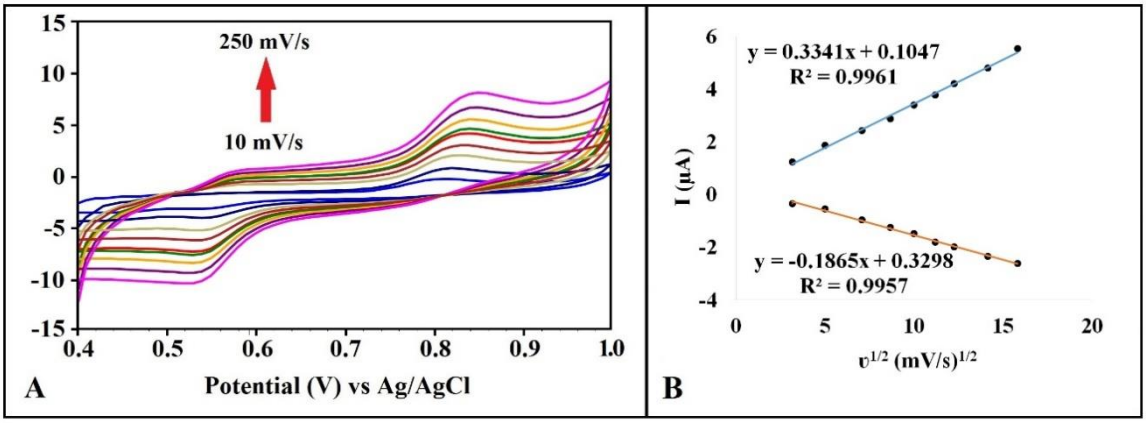

Figure 2. A) CVs of p-PGE of scan rate variation of 1 µM BB in 0.5 M HCl, B) Corresponding linear plots of I_{pa} and I_{pc} versus $v^{1/2}$

Effect of Supporting Electrolyte Type and Concentration

The electrochemical behavior of 1.0 µM BB on the p-PGE electrode was investigated in various types of supporting electrolytes prepared at a concentration of 0.1 M. As shown in Figure 3A, the highest current response was obtained in 0.1 M HCl, indicating that HCl supporting electrolyte provides the most favorable medium for the BB. Based on this finding, HCl solutions with varying molarities were prepared and used as supporting electrolytes to evaluate the effect of acid concentration on the electrochemical response of BB. As illustrated in Figure 3B, the maximum current signal was recorded in 0.5 M HCl, accompanied by a shift of both anodic and cathodic peak potentials toward more positive values with increasing acid strength. Consequently, this HCl molarity was selected for use in the subsequent experiments.

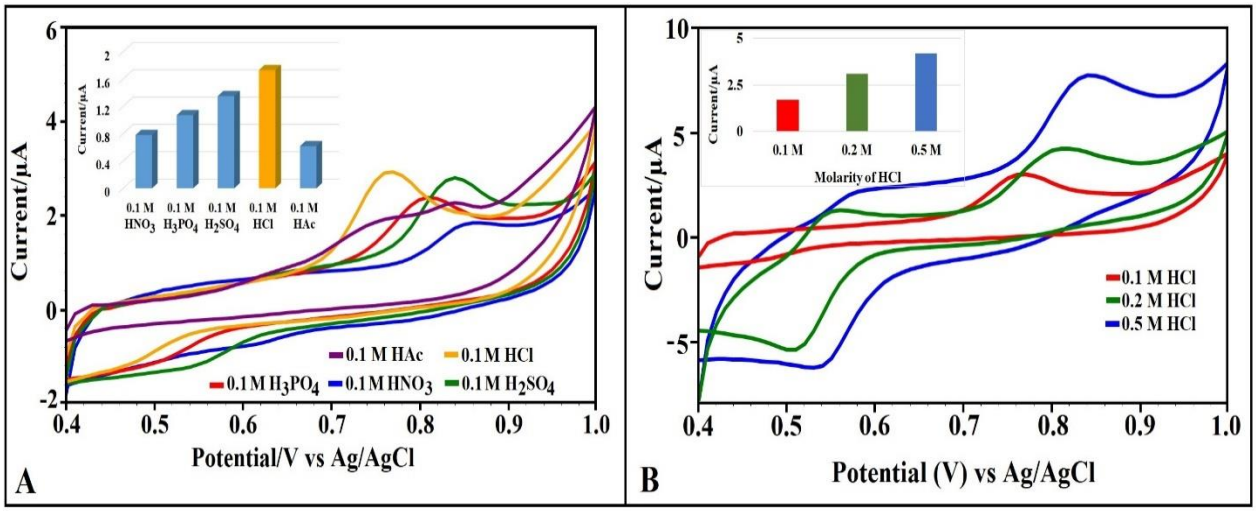

Figure 3. A) Comparison of 1 µM BB anodic currents in different 0.1 M supporting electrolytes, B) Influence of HCl concentration on the BB signal (oxidation peak). Scan rate 150 mV/s

Analytical Performance of p-PGE for Brilliant Blue Determination

The electrochemical behavior of Brilliant Blue at the p-PGE electrode was evaluated by recording CVs under optimized conditions, and the responses obtained at increasing BB concentrations were used to assess the analytical performance of the system. Although BB exhibited linear behavior for both its anodic and cathodic responses on the p-PGE surface, the anodic peak displayed a correlation coefficient closer to unity. Therefore, the analytical evaluations and the linear dynamic range were established based on the anodic signal. The concentration range evaluated for BB extended from 0.02 µM to 3.00 µM. As illustrated in Figure 4A, the cyclic voltammograms demonstrate a clear increase in peak current with rising BB concentrations. This trend is further confirmed in Figure 4B, where a linear relationship between peak current and BB concentration is observed. Based on this linear dependence, a regression model describing the correlation between BB concentration and peak current was derived: $I_{pa}=3.6963\times C_{BB} + 0.183$ ($R^2 = 0.9992$). Using the expression 3 × (SD/slope)-where SD represents the standard deviation associated with the lowest concentration yielding a quantifiable voltammetric response, the limit of detection (LOD) was calculated to be 8.5 nM.

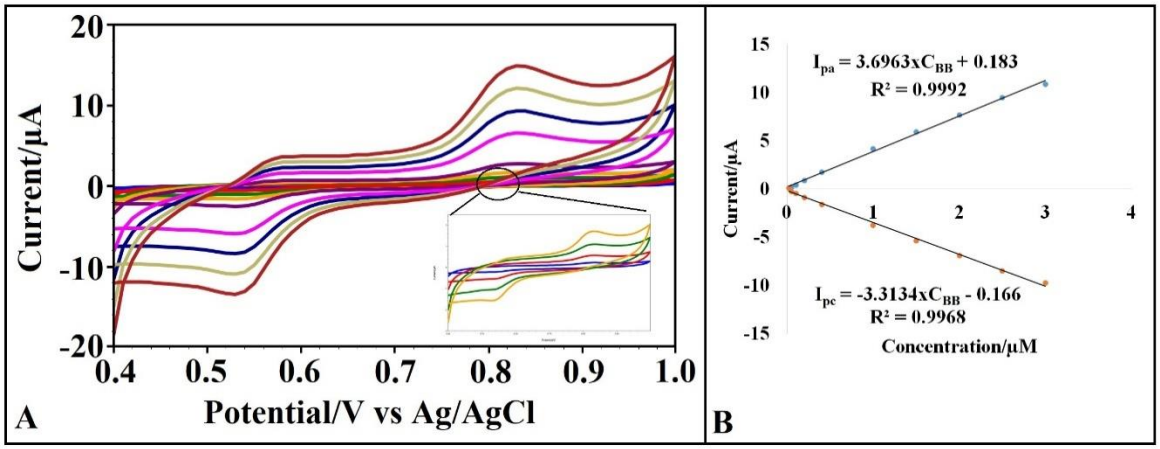

Figure 4. A) CV responses of BB with increasing concentrations from 0.02 µM to 3.00 µM in 0.5 M HCl, B) The calibration curve of the CV responses of BB; scan rate:150 mV/s

As presented in Table 1, the method developed in this work offers a **relatively** broad linear range and a reasonably low detection limit compared with previous reports. Considering its sensitivity and the practical benefits of electrochemical techniques, such as low cost and rapid measurements, the approach may be suitable for on-site analysis of BB.

Table 1. Comparison of previously reported methods for the determination of BB

Electrode	Linear Range (µM)	LOD (nM)	Reference
Boron-doped diamond electrode	0.596 - 9.90	13.1	(Medeiros et al., 2012)
Carbon black-polyethylene composite electrode	0.025 - 2.52	11.0	(Lipskikh et al., 2020)
A dual-templated molecularly imprinted polymer-based electrochemical sensor	0.02 - 0.38	8.36	(George et al., 2024)
Molybdenum disulphide/poly vinylpyrrolidone-GCE	0.8 - 1150	9.0	(Murali & Saraswathyamma, 2025)
p-PGE	0.02 - 3.00	8.5	This study

n=5

Reproducibility and stability of p-PGE

To assess the consistency of electrode fabrication, ten separate p-PGE were prepared for measuring 1 µM BB in 0.5 M HCl. The relative standard deviations (RSDs) of the anodic peak currents were found to be 2.27% for BB, demonstrating satisfactory reproducibility of the electrode preparation process. For evaluation of long-term stability, p-PGE was kept in ambient air at room temperature for a period of ten days. After ten days, the electrode retained 93.2% of the initial response for BB. These results suggest that the p-PGE possesses good stability over time.

Real Sample Analysis

To demonstrate the practical applicability of the developed method to real sample analysis, three different brands of energy drinks (EDs) purchased from a local market were analyzed. The samples were not subjected to any extraction. For dye content estimation, the standard addition method was used. BB standard solutions were added to real samples to achieve final concentrations of 0.5 and 1.5 µM. Table 2 presents the BB concentrations determined in the analyzed ED samples, employing the proposed CV and UV-Vis method.

Table 2. The results obtained from the analysis of real samples using the proposed voltammetric method were compared with those obtained via the reference spectrophotometric technique

	Electrochemical		UV-Vis		Calculated F_{table} (95%)	Teorical F_{table} (95%)
	Added	Found	Added	Found		
ED-1	0.50	0.47± 0.04	0.50	0.45±0.06	2.25	6.39
ED-2	1.50	1.54±0.03	1.50	1.56±0.05	2.78	6.39
ED-3	1.50	1.52±0.03	1.50	1.55±0.03	1.00	6.39

n=5

An F-test was applied to assess the variance between the electrochemical and spectrophotometric methods for determining BB in different ED samples. As shown in the table, the calculated F-values for ED-1 (2.25), ED-2 (2.78), and ED-3 (1.00) are all lower than the corresponding theoretical F-value at the 95% confidence level (6.39). This indicates that there is no significant difference in the precision of the results obtained by the two methods.

Interference Study

The potential interference from common food additives was examined. The results demonstrated that even large excesses up to 1000 times for glucose and fructose, 400 times for citric acid and ascorbic acid, and 50 times for tartrazine did not noticeably affect the electrochemical responses of 1 µM BB in optimized conditions.

CONCLUSION

In this study, a simple, cost-effective, and reusable pretreated pencil graphite electrode (p-PGE) was successfully developed for the sensitive voltammetric determination of BB in 0.5 M HCl. The p-PGE demonstrated a significantly enhanced electrochemical response compared to unpretreated electrodes, allowing for the detection of BB down to 8.5 nM with a wide linear range of 0.02-3.00 µM. The method exhibited excellent reproducibility and stability, maintaining over 93% of its initial response after ten days. Notably, the developed approach proved highly selective, as even large excesses of common food additives did not interfere with the detection of BB. Application to real energy drink samples showed good agreement with UV–Vis spectrophotometry, confirming its practical applicability. Overall, the proposed voltammetric method provides a rapid, reliable, and environmentally friendly alternative for the on-site analysis of BB in complex matrices.

Abstract

This research focused on creating and evaluating boric acid-loaded nanoemulsion (NE) and nanoemulgel (NEG) formulations that incorporate linseed oil, borage seed oil, or pumpkin seed oil for use in topical wound treatments. The NEs were manufactured through ultrasonic emulsification, utilizing Poloxamer 188 as the surfactant and Transcutol as the co-surfactant. These optimized NEs were transformed into NEGs by adding 1% xanthan gum in a 1:1 ratio. The formulations underwent analysis for droplet size, polydispersity index (PDI), and zeta potential, as well as pH, conductivity, rheology, and thermodynamic stability. After optimization, the NEGs were tested for their ability to combat biofilm formation against standard microbial strains. All NEs demonstrated favorable droplet sizes (<300 nm) and PDI values (<0.3), confirming their monodisperse nature. The incorporation of xanthan gel led to a reduction in droplet sizes across all formulations, indicating improved compactness and stability within the gel matrix. Among the NEGs, BSO-NEG had the smallest droplet size and the most negative zeta potential, suggesting strong electrostatic and thermodynamic stability. Each NEG showed varying levels of inhibition on bacterial adhesion and biofilm development. PSO-NEG demonstrated the highest efficacy against *E. faecalis*, whereas LSO-NEG and BSO-NEG effectively inhibited *S. aureus* biofilms. BSO-NEG and PSO-NEG diminished *E. coli* biofilms, with BSO-NEG further suppressing *K. pneumoniae* and *P. mirabilis*. Only LSO-NEG exhibited early suppression of *A. baumannii* adherence. Preliminary experiments demonstrated no efficacy against *P. aeruginosa*. In mature biofilms, all NEGs shown efficacy except against *K. pneumoniae*, with BSO-NEG exhibiting the highest activity against *S. aureus*, while LSO-NEG and BSO-NEG were most potent against *A. baumannii* and *P. mirabilis*. Among the formulations, BSO-NEG demonstrated the most promising broad-spectrum antibiofilm efficacy, effectively suppressing both early-stage and mature biofilms of many clinically relevant pathogens.

INTRODUCTION

Wound healing is a multifaceted and dynamic process comprising four consecutive yet overlapping phases: haemostasis, inflammation, proliferation, and remodeling (Landén et al., 2016). The successful progression of the healing process depends on the control of inflammation, prevention of infection, and stimulation of tissue regeneration. However, local factors such as oxygenation and infections or systemic factors such as age, hormones, diseases and medications may cause wound healing to be delayed or become chronic (Guo and DiPietro, 2010). Since infection is the main cause of chronic wounds, controlling microbial contamination and colonization is a crucial step for wound healing (Landis, 2008). Chronic wound infections often present as persistent and prolonged conditions, in which biofilm phenotype plays a central pathogenic role. Whereas planktonic bacteria involved in acute, invasive infections are typically eradicated by the host's innate immune defenses and antibiotic treatment, chronic wounds remain refractory and slow to heal (Hurlow and Bowler, 2022).

Given the importance of infection control and tissue regeneration in wound management, innovative topical delivery techniques are increasingly needed to overcome the limits of existing topical formulations. Nanoemulsions (NEs) are heterogeneous colloidal systems composed of oil and water, in which one phase is dispersed within the other as the continuous phase. An emulsifier, which is a type of surfactant, is absorbed at the interface between the dispersed and continuous phases. This lowers surface tension and stabilizes the system (Donthi et al., 2023). Furthermore, the nanoscale droplet size of NEs increases the solubility of medications

and promotes skin penetration, making them suitable for topical application. Notwithstanding their numerous benefits, NEs are constrained by low viscosity, leading to inadequate adherence to the skin. This constraint can be surmounted by converting the NE into a nanoemulgel (NEG) via the integration of a suitable gelling agent (Donthi et al., 2023).

Linseed oil (LSO) is recognized as one of the richest natural sources of polyunsaturated fatty acids (PUFA) and essential fatty acids (EFA). LSO predominantly contains α-linolenic acid (ALA) and linoleic acid, together with monounsaturated oleic acid (Franco et al., 2012; Poljšak et al., 2020). LSO's unsaturated fatty acids promote growth factor synthesis, fibroblast proliferation, and angiogenesis, which accelerate tissue regeneration and wound healing (Franco et al., 2012). The fatty acids and phenolic constituents of linseed, particularly caffeic acid and coumaric acid, significantly enhance its antioxidant capacity and support wound healing (Wang et al., 2017). Borage seed oil (BSO), high in γ-linolenic acid (GLA), has anti-inflammatory, antioxidant, and skin-regenerating properties. Its polyphenols and GLA scavenge free radicals and protect collagen and elastin fibers by blocking collagenase and elastase, which may aid wound healing (Michalak et al., 2023). Poljšak et al. (2020) found that pumpkin seed oil (PSO) is a natural oil high in PUFA, including linoleic acid, monounsaturated fatty acids like oleic acid, and lower levels of saturated fatty acids like palmitic and stearic acids. In addition to its fatty acid profile, phytosterols, tocopherols, and phenolic acids contribute to its antioxidant, anti-inflammatory, and wound-healing properties (Prommaban et al., 2021).

Boric acid possesses numerous advantageous effects on wound healing, including antibacterial, anti-inflammatory, antioxidant, and angiogenic properties. It exhibits significant antibacterial effectiveness by increasing pathogen cell wall permeability, compromising cell membranes, and inhibiting cell membrane synthesis, thereby reducing infection risk (Liu et al., 2021; Guner et al., 2025). Furthermore, the antioxidant characteristics of boric acid mitigate oxidative stress, safeguarding cells and facilitating tissue regeneration (Sedighi-Pirsaraei et al., 2024).

The aim of this study was to develop stable and effective topical NEG formulations. To achieve this, we used ingredients such as boric acid, LSO, BSO and PSO, and examined essential physicochemical properties such as droplet size, polydispersity index (PDI) and zeta potential. The improved NEs were then mixed with gels made from xanthan gum to create the final NEG systems. These systems underwent comprehensive testing to assess their performance across a range of temperatures, mobility, and effectiveness in eliminating bacteria such as *Staphylococcus aureus* (*S. aureus*) ATCC 29213, *Enterococcus faecalis* (*E. faecalis*) ATCC 29212, *Escherichia coli* (*E. coli*) ATCC 25922, *Klebsiella pneumonia* (*K. pneumonia*) ATCC 4352, *Proteus mirabilis* (*P. mirabilis*) ATCC 14153, *Pseudomonas aeruginosa* (*P. aeruginosa*) ATCC 27853, and *Acinetobacter baumannii* (*A. baumannii*) ATCC 19606.

MATERIALS and METHODS

Materials

Boric acid (B0394-500G, Sigma-Aldrich, USA) was used as the main active ingredient. Kolliphor® P188 (Poloxamer 188, BASF, Germany) served as a surfactant. The oil phase consisted of LSO and BSO (Nuka Defne Esencia®, Türkiye) and PSO (Intense Natural®, Türkiye). Xanthan gum (Vanzan® NF-C, Vanderbilt Minerals, USA) was used as the gelling polymer. Transcutol® (Gattefossé, France) and Sensiva® PA30 (Schülke & Mayr GmbH, Germany) were incorporated as cosurfactant and skin-conditioning agents. α-Tocopherol acetate (Sigma-Aldrich, Germany) was added as an antioxidant. All other reagents were analytical grade, and deionized water was used throughout the study.

Methods

Nanoemulsion and nanoemulgel preparation

In this study, NE formulations containing 3% boric acid and 3% of each oil (LSO, BSO, and PSO) were individually prepared using the ultrasonic emulsification method. To determine the optimal formulations, various parameters such as oil concentration, surfactant concentration, and the oil-to-surfactant ratio were evaluated. The ultrasonication process was carried out at 50% amplitude, with a pulse sequence of 30 seconds on and 30 seconds off to avoid excessive heating. Ultrasonication was applied at a frequency of 20 kHz for a total of 10 minutes. Throughout the experiment, the temperature was maintained constantly by using an ice bath. After the optimization of the NEs were completed, the gel containing 1% xanthan gum was mixed with the NE at a 1:1 (w/w) ratio using a magnetic stirrer at 500 rpm for 30 minutes.

Nanoemulsion and nanoemulgel characterization

Droplet size, polydispersity index and zeta potential

Dynamic light scattering (DLS) was used with a Zetasizer Nano ZS (Malvern Instruments, UK) at 25 ºC and a 90º scattering angle to examine the mean droplet size and PDI of the formulations. Formulations were considered monodisperse if their PDI values were less than 0.3, and samples were diluted 1:100 (v/v) with deionized water to avoid multiple scattering. Zeta potential was determined using electrophoretic mobility using the same apparatus, with materials diluted 1:100 (v/v) and analyzed at 25 ºC (Kildaci et al., 2021).

pH, conductivity, and rheological properties

The pH and conductivity of the NEGs were determined at 25 ºC using a portable pH/conductivity meter (Hanna Edge, USA). Viscosity measurements were performed with a Brookfield cone-plate viscometer (Brookfield Engineering Laboratories, MA, USA) different shear rates to assess the flow behavior (Ozkan et al., 2022).

Studies of thermodynamic stability

The formulations were centrifuged at 3500 rpm for 30 minutes (Thermo Scientific, USA) and then heated to 60 ºC in a thermostatic water bath (Witeg WSB-30, Germany) to test their physical stability. Prior to gel inclusion, only formulations free of instability and phase separation were chosen.

Evaluation of anti-biofilm activities of the optimized nanoemulgel formulations

Strains and culture conditions

The following strains were subcultured from freezer stocks onto tryptic soy agar (TSA, Difco, Sparks, MD, USA) and incubated at 37 ºC overnight: *S. aureus* ATCC 29213, *E. faecalis* ATCC 29212, *E. coli* ATCC 25922, *K. pneumoniae* ATCC 4352, *P. mirabilis* ATCC 14153, *P. aeruginosa* ATCC 27853 and *A. baumannii* ATCC 19606.

Inhibition of biofilm adhesion and formation

Bacterial cultures were prepared to an equivalent cell density to 1×10^6 cfu/mL in Brain-heart infusion broth (BHIB, Thermo Scientific, Oxoid, USA) and were added to each well of 96-well tissue culture microtiter plate (Greiner Bio-One, Kremsmuenster, Austria) containing the optimized NEGs formulation. In addition, positive controls without antimicrobials and negative controls without cells were added. The plates were incubated at 37 ºC for 1, 2, 4 and 24 hours. Following the incubation period, the wells were washed twice with physiologically buffered saline (PBS). Spectrophotometric analysis was then conducted at an optical density (OD) of 450 nm using a microplate reader (EON, Biotek, USA) (Aydın et al., 2025).

Effects on mature biofilms

Biofilm formation was conducted in flat-bottomed 96-well polystyrene tissue culture microtiter plates. Overnight bacterial cultures were prepared in BHIB, to a cell concentration of 1×10^6 cfu/ml. Biofilms were formed by adding the bacteria into appropriate wells of microtiter plates and incubating them for 24 hours at 37 ºC. Subsequent to this incubation period, the waste material was gently aspirated, and non-adherent bacteria were removed by washing the biofilms twice with sterile PBS.

Following the formation of mature biofilms, NEGs, positive and negative controls were added, and the microtiter plates were incubated at 37 ºC for another 24 hours. After this period, wells were washed again with PBS and analyses were performed using the 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyl tetrazolium bromide (MTT) method. The MTT solution was added to the wells, and the plates were incubated in the dark at 35 ºC for 3 hours. Following incubation, the resulting formazan crystals were dissolved in DMSO (Sigma-Aldrich, St. Louis, MO, USA), and the optical densities were measured at 490 nm using an ELISA microplate reader (EON, Biotek, USA). The results were then evaluated by comparison with the control (Aydın et al., 2025).

RESULTS and DISCUSSION

Preparation and characterization of nanoemulsion formulations

The preliminary evaluation of the NE formulations was carried out using mean droplet size (Z-Ave), PDI, and zeta potential (mV) as key indicators. Formulations exhibiting small droplet sizes (<300 nm), low PDI (<0.3), and high negative zeta potential (>|30| mV) were considered stable.

According to the initial physicochemical evaluation, all three NE formulations had the desired droplet sizes and low PDI values, indicating a narrow size distribution and uniform droplet dispersion (Table 1). Among the formulations, The NEs containing PSO (PSO-NE) had a larger negative zeta potential (-33.43 mV) and the lowest PDI value (0.191). The NEs containing LSO (LSO-NE) and BSO (BSO-NE) demonstrated moderate electrostatic stability, with zeta potentials of -18 and -21.4 mV, respectively. Overall, these results show that all formulations were successfully synthesized as homogeneous NEs.

Evaluation of thermal and centrifugation stability of nanoemulsions

Centrifugation and thermal stress tests demonstrated that all formulations maintained homogeneity and monodispersity, as evidenced by their consistent PDI values and comparable droplet sizes. Both PSO-NE and BSO-NE maintained stable zeta potential values under stress conditions, demonstrating stronger electrostatic stability compared to LSO-NE. In contrast, LSO-NE exhibited a noticeable reduction in zeta potential following centrifugation and thermal stress, as presented in Table 1.

Table 1. Mean droplet size (Z-Ave), PDI, and zeta potential (mV) values of NE at T0, centrifugation and thermal stress test.

Formulation Code	T0			Centrifugation Test			Thermal Test (60 °C)		
	Z-Ave (nm)	PDI	Zeta Potential (mV)	Z-Ave (nm)	PDI	Zeta Potential (mV)	Z-Ave (nm)	PDI	Zeta Potential (mV)
LSO-NE	114.10	0.205	-18.00	107.10	0.188	-12.40	103.60	0.198	-13.30
BSO-NE	114.25	0.199	-21.40	113.85	0.192	-23.23	118.68	0.183	-21.90
PSO-NE	114.85	0.191	-33.43	115.63	0.198	-33.40	116.55	0.198	-25.80

Preparation and characterization of nanoemulgel formulations

When the NEs was combined with the gel, the droplet size decreased from 114.1 nm to 93.3 nm in LSO-NEG, from 114,25 nm to 69.36 nm in BSO-NEG and from 114.85 nm to 95.34 nm in PSO-NEG, indicating that integration into the gel matrix resulted in more compact and stable systems (Table 2). Although the PDI values increased slightly following the integration of the gels, they remained below 0.33, indicating that all of the NEGs had a restricted size distribution and good colloidal homogeneity. Notably, the transition from NE to NEG resulted in reduced zeta potential values for LSO-NEG and BSO-NEG, suggesting enhanced electrostatic stability in the gel state. In contrast, PSO-NEG had a slightly lower magnitude of zeta potential than PSO-NE yet still retained sufficient negative charge to ensure colloidal stability. Overall, these findings suggest that the addition of xanthan gum improves the structural compactness and electrostatic stability of the NEGs.

Evaluation of thermal and centrifugation stability of nanoemulgels

Table 2 shows the centrifugation and heat stability data for the NEG formulations. The physicochemical stability of the NEG formulations was assessed after centrifugation and heat stress at 60 °C. BSO-NEG had the smallest initial droplet size and a strong negative zeta potential, indicating high electrostatic stability, albeit droplet size increased slightly when stressed. LSO-NEG demonstrated moderate stability with small changes in droplet size and PDI, but PSO-NEG showed a significant decrease in zeta potential after centrifugation and thermal stress, indicating lower electrostatic stability.

Table 2. Mean droplet size (Z-Ave), PDI, and zeta potential (mV) values of NEG at T0, centrifugation and thermal stress test.

Formulation Code	T0			Centrifugation Test			Thermal Test (60 °C)		
	Z-Ave (nm)	PDI	Zeta Potential (mV)	Z-Ave (nm)	PDI	Zeta Potential (mV)	Z-Ave (nm)	PDI	Zeta Potential (mV)
LSO-NEG	93.30	0.299	-25.60	78.93	0.332	-25.50	80.71	0.326	-30.70
BSO-NEG	69.36	0.275	-38.80	85.93	0.302	-38.50	91.96	0.304	-30.73
PSO-NEG	95.34	0.258	-28.43	88.23	0.254	-19.43	85.19	0.253	-19.00

pH, conductivity and rheological evaluation

The pH values of the formulations listed in Table 3 were all found to be within the physiological range of human skin (4.5-6.0). These results show that the formulations are compatible with pH and unlikely to cause irritation, indicating that they are suitable for topical administration.

Conductivity tests are critical for identifying whether NEG systems' external phase is aqueous and evaluating the stability of their ionic structure. The conductivity values for LSO-NEG, BSO-NEG and PSO-NEG were measured as 583 µS, 446 µS and 1056 µS, respectively (Table 3), indicating that the external phase was aqueous. As a result, all three systems showed O/W NEG configuration.

Table 3. pH and conductivity (µS) values.

Formulation Code	pH (25 °C)	Conductivity (µS) (25 °C)
LSO-NEG	5.51	583
BSO-NEG	5.54	446
PSO-NEG	5.49	1056

As illustrated in Figure 1, the viscosity profiles of the LSO-NEG, BSO-NEG and PSO-NEG formulations demonstrated a decrease in viscosity with increasing shear rate. This observation confirms that all three formulations exhibit non-Newtonian, shear-thinning (pseudoplastic) flow behavior.

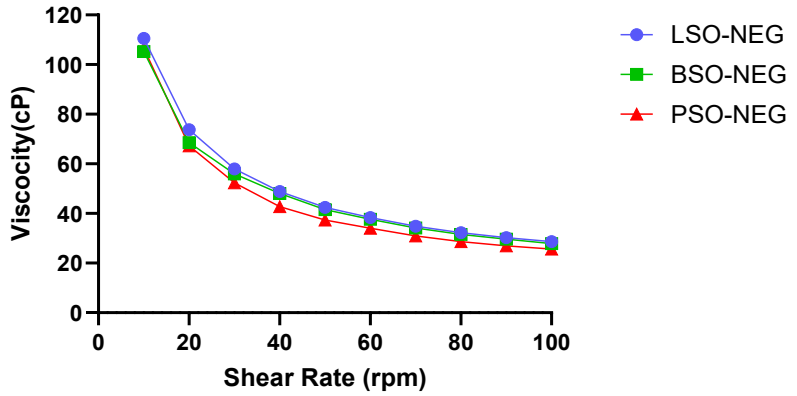

Figure 1. Viscosity-Shear rate graph.

Evaluation of anti-biofilm activities of the optimized nanoemulgel formulations

Inhibition of adhesion and biofilm formation

All the compounds, in varying ratios, had an inhibitory effect on *E. faecalis* adhesion and biofilm formation for almost all the hours studied. The most effective compound for this bacterium was PSO-NEG. Placebo, BSO-NEG and LSO-NEG showed inhibitory effects against *S. aureus* biofilm formation. Against *E. coli*, PSO-NEG and BSO-NEG showed inhibitory effect on biofilm formation (24 h), while BSO-NEG also showed inhibition of *K. pneumoniae* and *P. mirabilis* biofilm formations by 15% and 9%, respectively. Between the compounds, significant inhibitor effect on *A. baumannii* adhesion was seen at LSO-NEG and only at the end of the 1st hour (%16.8). The compounds showed no inhibitory effect against *P. aeruginosa* adhesion and biofilm formation. Results were shown in Figure 2.

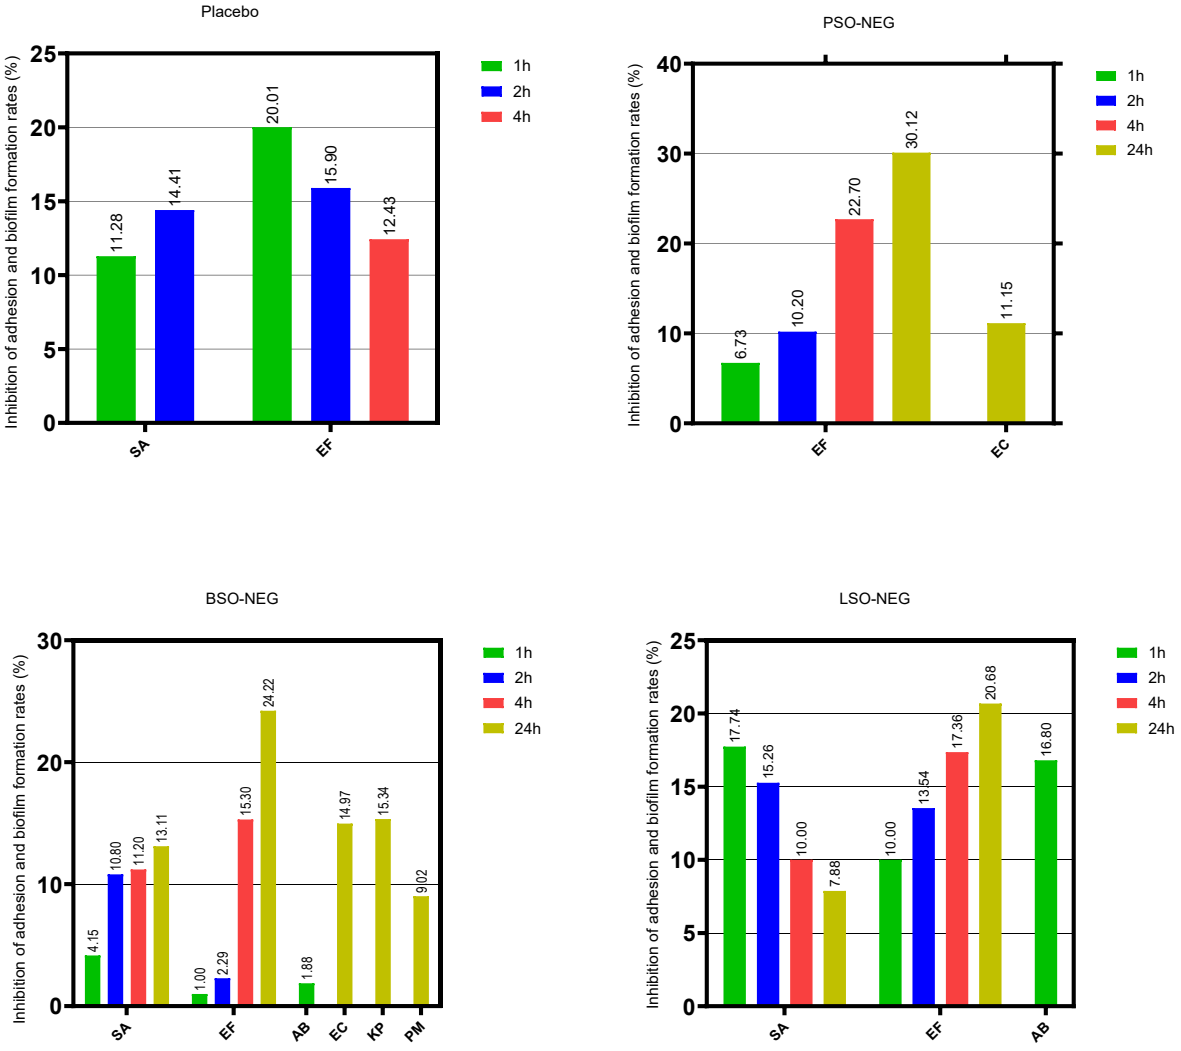

Figure 2. Inhibition of adhesion rates (%) of antimicrobials after 1, 2, 4 and 24 h incubation. Only the bacteria in which the NEGs are effective are shown in the graphs.

SA: *S. aureus*, EF: *E. faecalis,* PA: *P. aeruginosa* AB: *A. baumannii,* EC: *E. coli*, PM: *P. mirabilis*, KP: *K. pneumoniae*

Effects on mature biofilms

Placebo is only slightly effective against *E. faecalis*, else it is not effective against any bacteria. The other NEGs are effective in varying degrees on mature biofilms of all bacteria, except *K. pneumoniae*. The most effective compound against *S. aureus* was BSO-NEG, with an inhibition rate of 37%. All NEGs formulations showed similar inhibitory effects on mature biofilms of *E. faecalis* and *E. coli*. LSO-NEG and BSO-NEG were the most effective against mature biofilms of *A. baumannii*, and LSO-NEG was the most effective against *P. aeruginosa*.

Against mature biofilms of *P. mirabilis*, LSO-NEG and BSO-NEG were the most effective with inhibition rates above 40%. The minimum effect was observed against *K. pneumoniae* biofilms. Results are shown in Figure 3.

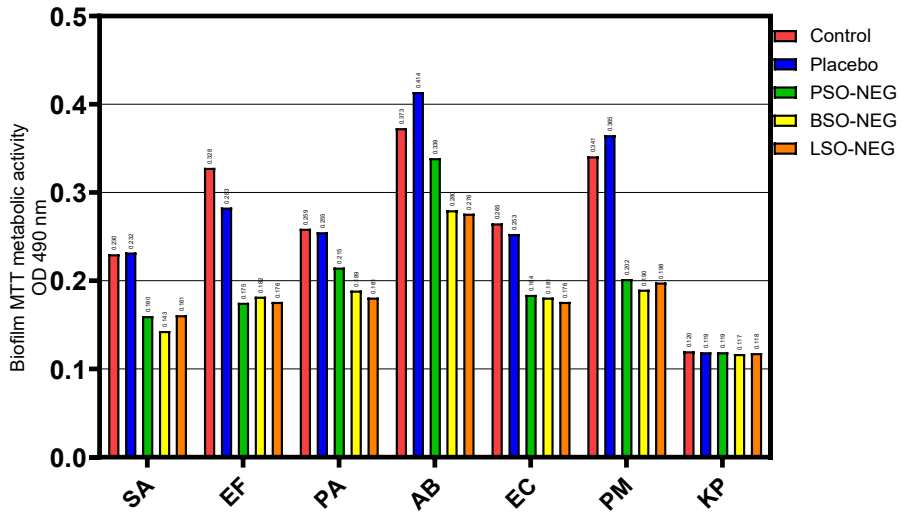

Figure 3. Effects of compounds on mature biofilms, by MTT method. Bars indicate control and NEG formulations, respectively on 24-hour-old mature biofilms.

SA: *S. aureus*, EF: *E. faecalis,* PA: *P. aeruginosa* AB: *A. baumannii,* EC: *E. coli*, PM: *P. mirabilis*, KP: *K. pneumoniae*

CONCLUSION

This research successfully created stable and biocompatible NEGs by incorporating LSO, BSO, and PSO oils into a xanthan-gum matrix to improve topical antibiofilm effectiveness. The transition from NEs to NEGs resulted in smaller droplet sizes across all formulations. Among them, BSO-NEG had the smallest droplet size and the most favorable zeta potential, indicating high electrostatic stability, while LSO-NEG and PSO-NEG displayed moderate electrostatic stability. Each formulation had a skin-friendly pH, O/W properties, and shear-thinning pseudoplastic flow, indicating its suitability for skin application. In antibiofilm studies, all NEGs reduced early adhesion and biofilm formation to various degrees. PSO-NEG was very efficient against *E. faecalis*, while BSO-NEG and LSO-NEG both inhibited *S. aureus*. Both PSO-NEG and BSO-NEG were effective at reducing *E. coli* biofilms, with BSO-NEG additionally targeting *K. pneumoniae* and *P. mirabilis*. LSO-NEG specifically inhibited the early stages of *A. baumannii*. No formulation affected *P. aeruginosa* in initial stages. The placebo showed minimal activity, confirming the functional contribution of the NEG systems. Against mature biofilms, all NEGs showed meaningful activity except *K. pneumoniae*. BSO-NEG was the most effective against *S. aureus*, and all NEGs produced similar reductions in *E. faecalis* and *E. coli* mature biofilms. LSO-NEG and BSO-NEG were the most effective against mature *A. baumannii* and *P. mirabilis* and LSO-NEG was the most effective against *P. aeruginosa.* Overall, LSO, BSO and PSO-based NEGs represent a promising, plant-derived topical delivery system for interfering with early and mature biofilms of clinically relevant bacteria. Although they lack antibacterial effects on planktonic cells, their targeted antibiofilm performance and favorable topical properties highlight their potential as next-generation wound care nanocarriers for preventing and managing biofilm-associated infections.

ORAL PRESENTATION

Kenevir-beton yalıtımlarının kuruma hızı ve etkin nem difüzyon katsayılarının tahmini

F. Nihal Tüzün (*0000-0001-5363-9711*)

Hitit Üniversitesi, Mühendislik ve Doğa Bilimleri Fakültesi, Kimya Mühendisliği Bölümü, Çorum, Türkiye

Sorumlu yazar e-mail:nihaltuzun@yahoo.com

Özet

Bina sektöründe üretilen sera gazlarını azaltmak için duyulan ihtiyaç geleneksel olarak kullanılan yalıtım malzemelerinin yerine yenilenebilir ve daha az darbe etkisi yaratan malzemelerin araştırılmasına neden olmaktadır. Bu konu biyokompozit betonların araştırılmasını teşvik etmiş ve düşük maliyetli üretim prosesi olan lifli bitkisel malzemelerin beton içerisinde kullanılması sağlanmıştır. Bu biyokompozit beton normal betondan daha hafiftir ve üzerine fazla yük uygulanamamaktadır. Kenevir bitkisi ile sönmüş kireç ve su karışımından oluşan bu biyokompozite kenevir-beton denmektedir. Bu çalışmada, binalarda yalıtım malzemesi olarak kullanılmak üzere 7 adet kenevir-beton kompozisyonu geliştirildi. Hazırlanan bu kompozisyonlardan 4 tanesi yalnızca kenevir sapları kullanılarak hazırlanırken, diğer 3 tanesi ise hem kenevir sapları hem de lifleri kullanılarak hazırlandı. Geliştirilen bu kompozisyonlar, 16,4^{0}C -22^{0}C sıcaklık aralığında ve %29-45 bağıl nem değişimi gösteren depolama odasında doğal konveksiyonla kurutularak kürlenmeleri sağlandı. Kenevir-beton karışımlarının kuruma hızları ve kurutma işlemi sırasındaki nem değişimleri ve kuru yoğunlukları belirlenerek, kısa ve uzun difüzyon süreleri için etkin nem difüzyon katsayıları hesaplandı. Kürlenme ve kuruma sürelerinin, kenevir-beton kompozisyonlarının; su içeriği, kenevir ve lif etkilerine bağlı olarak değiştiği görüldü. Ayrıca, lifli kompozisyonlarda kuruma hızının lifsiz kompozisyonlara göre daha düşük olduğu bulundu. Bunun yanında, lifli M kompozisyonu hariç, uzun difüzyon sürelerinde kısa difüzyon sürelerinden daha düşük etkin nem difüzyon katsayıları hesaplandı.

Anahtar Kelimeler: Kenevir-beton, yalıtım, kuruma hızı, etkin difüzyon katsayısı, kenevir sapı, kenevir lifi

Estimation of drying rate and effective moisture diffusion coefficients for hempcrete insulations

Abstract

The need to reduce greenhouse gases produced in the building sector has led to the search for renewable and less impact-intensive materials to replace traditionally used insulation materials. This has spurred research into biocomposite concrete, enabling the use of fibrous plant materials within the concrete, a cost-effective production process. This biocomposite concrete is lighter than conventional concrete and cannot be subjected to excessive loads. This biocomposite, composed of a mixture of hemp plants, hydrated lime, and water, is called as hempcrete. In this study, seven hempcrete compositions were developed for use as insulation materials in buildings. Four of these compositions were prepared using only hemp stalks, while the other three used both hemp stalks and fibers. These compositions were dried and cured by natural convection in a storage room with a temperature range of 16.4°C to 22°C and a relative humidity of 29% to 45%. Drying rates, moisture changes during drying, and dry densities of hempcrete compositions were determined, and effective moisture diffusion coefficients were also calculated for short and long diffusion times. Curing and drying times were found to vary depending on the water content, hemp, and fiber effects of the hempcrete compositions. Furthermore, drying rates were found to be slower for the hempcrete compositions having fibers. Thus, lower effective moisture diffusion coefficients were calculated for long diffusion times than for short diffusion times, except for the composition M including fiber.

Keywords: Hempcrete, insulation, drying rate, effective diffusion coefficient, hemp stalk, hemp fiber

GİRİŞ

Gözenekli katılarda kurutma yöntemlerine baktığımızda; katı içerisindeki nemin yüzey hareketinin kılcal akış hareketi ile meydana geldiğinden bahseden kılcal akış teorisi, nemi yüzeye ulaştıran etkinin hem difüzyon hem de kılcal etkinin toplamı olduğunu belirten Krischer teorisi ve Krischer teorisine nemlendirme ısısının ve duyulur ısı transferinin katılması ve sıvı ve buhar fazlarında nem içeriği değişimlerinin ayrılması ile de DeVries teorisi geliştirilmiştir. Ancak, Krischer teorisinde kurutma zamanının doğru şekilde hesaplanabilmesi için gözenekli cismin kılcal geçirgenlik ve difuzyonal direnç katsayısının bilinmesi gerekmektedir. Bu iki katsayı da genellikle gözenekli cisimde gözeneklerin yapısına, sıcaklığına ve nem dağılımına bağlıdır. DeVries teorisinde ise, kolay algılanabilir fiziksel temeline rağmen difüzyon denklemlerine benzeyen denklemlerinin katsayılarının hem dikkatli deneyler sonucu saptanabilmesi hem de bu yaklaşımla gerçek kurutma koşullarındaki kurutma olayını açıklamanın zorluğu bu teorinin çok fazla rağbet görmesini engellemiştir.
Kenevir-beton yavaş kuruyan bir malzeme olduğundan ve difüzyon da, yavaş kuruyan malzemelerin karakteristik davranışı olduğundan Difüzyon teorisine göre katının iç kısımlarındaki suyun yüzeye hareketi katı içi difüzyonla gerçekleşir. Fick'in 2. kanununa uyan buhar veya sıvıların transferinde bu tip difüzyon kontrollü kütle transferinin olduğu bu çalışmada da varsayılmıştır. Katı yüzeyinden havaya su buharının kütle transferi direnci genellikle ihmal edilir ve bütün kuruma hızını katıdaki difüzyon kontrol eder. Böylece yüzeydeki nem içeriği denge değerindedir veya denge değerine çok yakındır (Chen ve ark., 2018).
Kenevir-beton üretiminden sonra, kenevir parçaları ve hidrasyon reaksiyonları muhtemelen 2 ila 5 gün arasında su tüketmektedir. Erken yaşlanma döneminden sonra, hidrasyon reaksiyonu ve numune ile çevre arasındaki su transferi birlikte gerçekleşir. Başlangıçta su sıvı fazdadır, difüzyon yoluyla numunenin yüzeyine taşınabilir ve kalan su içeriği yakalanana kadar yüzeydeki havaya buharlaşır. Açık yüzeylerden kütle kaybından kaynaklanan bu işleme kurutma denir (Evrard, 2008) ve bu işlem blok boyutuna bağlı olarak birkaç hafta sürer (Glouannec ve ark., 2010).
Kurutma aşamasının tamamlanmasıyla, kireç bazlı bağlayıcılardaki (Gu ve Song, 2010) son derece yavaş karbonatlaşma reaksiyonu (Lawrence ve ark., 2007) nedeniyle az miktarda serbest su salınır.
Bu çalışmada, geliştirilen 3 adedi lifli olmak üzere 7 adet kenevir-beton kompozisyonların kürlenme süreci boyunca malzeme içerisindeki su transferine bağlı kuruma hızı ve yoğunluk değişimi kısa süreli ve uzun süreli difüzyon süreci için etkin nem difüzyon katsayıları da dahil olmak üzere taşınım parametreleri açısından incelenmiştir.

MATERYAL VE METOT

Bu çalışmada, 7 adet kenevir-beton kompozisyonu geliştirildi. Kompozisyonların 4 adedi sönmüş kireç, su ve yalnızca Çorum ili Mecitözü ilçesinde hasat edilen endüstriyel kenevirin saplarından oluşurken, diğer 3 adedi ise, sönmüş kireç, su ve kenevir saplarının yanında endüstriyel kenevir liflerinin de ilave edilmesiyle hazırlandı. Hazırlanan bu kompozisyonlar 5 dakika karıştırıldıktan sonra, 5400 cm^3 hacmindeki blok şeklindeki kalıplara dolduruldu ve titreşim uygulanarak içerisindeki hava kabarcıkları giderildi. 1 gün sonra kalıplar çıkarıldı ve bloklar, numune ile ortam arasında su alışverişini önlemek için 16,4^{0}C -22^{0}C sıcaklık değişimine ve %29-45 bağıl neme sahip depolama odasında doğal konveksiyonla kurutularak kürlenmesi sağlandı. Depolama odasının sıcaklık ve hava bağıl nem ölçümleri ThermoPro TP 49 model dijital termohigrometre ile yapıldı.

Kurutma işlemi, blok kütlesi sabitlenene kadar devam ettiğinden belli aralıklarla blok kütleleri tartıldı. Blok kütlesinin ölçümü, 0,1 g hassasiyete sahip dijital tartı cihazı ile gerçekleştirildi. Kurutma süresi boyunca, bloğun kütle değişiminin yalnızca malzemenin su kaybına bağlı olduğu varsayıldı. Bu nedenle, blokların ağırlık ölçümü iki farklı eğri verdi. Bunlardan biri, zamana bağlı olarak su içeriği değişimini (kuru baz) içeren kurutma eğrisi, diğeri ise, kuruma yüzey alanı ve zaman başına kütle kaybı hızını tanımlayan kuruma hızı eğrisidir (Colinart ve ark., 2012). Blokların kürlenme süresi boyunca, numunelerde suya bağlı olarak bazı reaksiyonlar ve olaylar meydana gelmiştir. Bunlar, hidrasyon reaksiyonları, karbonatlaşma reaksiyonları ve suyun merkezden yüzeye difüzyonu, yüzeyden buharlaşma ve havaya geçişidir (Colinart ve ark., 2012).

Etkin nem difüzyon katsayısının tahmini

Kuruma periyodu, gözenekli ortamın yüzeyine kararsız haldeki nemin (sıvı veya buhar) difüzyonu ile gerçekleşen başlıca taşınım olaylarından biri olarak tanımlanabilir ve denklem (1)'de gösterildiği gibi Fick'in ikinci difüzyon yasası ile yorumlanabilir.

$$\frac{\partial X}{\partial t} = Dw\nabla^2 X \quad (1)$$

X, kuru baz nem içeriğidir,
t, zamandır ve
Dw, malzemenin etkin nem difüzyon katsayısıdır.

Denklem (1)'de verilen Fick denkleminin analitik çözümü, Denklem (2)'de dikdörtgen bir levha için, düzgün başlangıç nem dağılımı (X0), numune yüzeyinde sabit konsantrasyon, sabit levha kalınlığı (L) ve sıfıra yakın son denge nem içeriği (Xeq) dikkate alınarak ifade edilmiştir (Crank, 1975).

$$\text{Xred}= \frac{8}{\pi^2} \sum_{n=0}^{\infty} \frac{1}{(2n+1)^2}\, e^{-\left[\frac{(2n+1)^2\times\pi^2\times Dw}{4L^2}\times t\right]} \quad (2)$$

Xred, Denklem (3) ile açıklanan boyutsuz nem içeriği oranıdır.

$$\text{Xred}= \frac{\bar{X}-Xeq}{X0-Xeq} \quad (3)$$

X nem içeriğidir,
Xeq; denge nem içeriğidir ve
X0; başlangıç nem içeriğidir.
Denklem (2), difüzyon sürecinin başlangıcı ve sonu olmak üzere iki farklı zaman dilimi için doğrusallaştırılabilir. Kısa difüzyon süresi için Denklem (2), Denklem (4) (Bakhshi ve Mobasher, 2011) olarak yazılabilir.

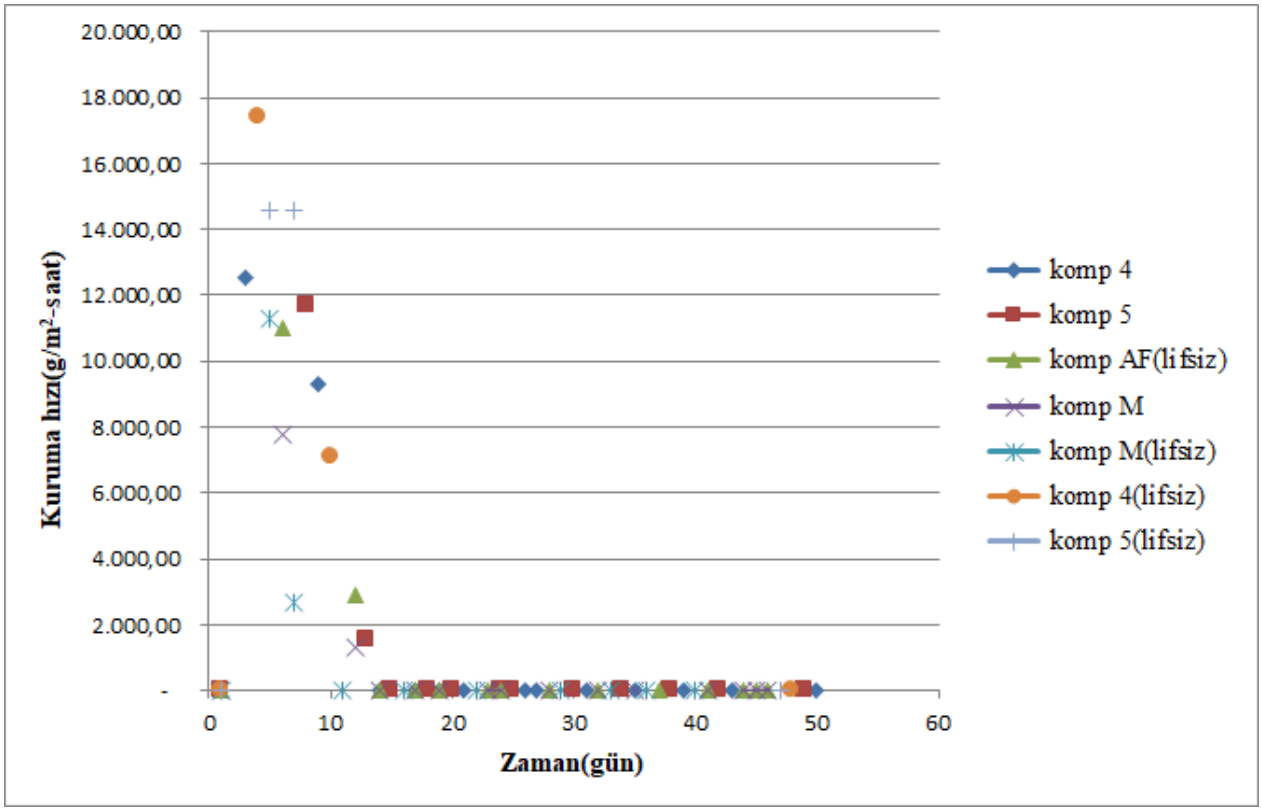
$$Xred = 1 - 2\sqrt{\frac{Dw}{\pi\times L^2}}\times t \quad (4)$$

ve Denklem (5)'de gösterildiği gibi zamanın doğrusal bir fonksiyonuna sadeleştirilebilir.

$$\left(\frac{\pi\times L^2}{4}\right)(Xred-1)^2 = Dw\times t \quad (5)$$

Uzun difüzyon süresi için, Denklem (2), Denklem (6)'ya dönüştürülebilir (Bakhshi ve Mobasher, 2011).

$$\text{Xred}= \frac{8}{\pi^2} e^{-\left[\frac{\pi^2\times Dw}{4L^2}\times t\right]} \quad (6)$$



Denklem (7) de zamanın doğrusal bir fonksiyonuna sadeleştirilebilir.

$$\frac{4L^2}{\pi^2}\left[\log\left(\frac{8}{\pi^2}\right)-\log(Xred)\right] = Dw\times t \quad (7)$$

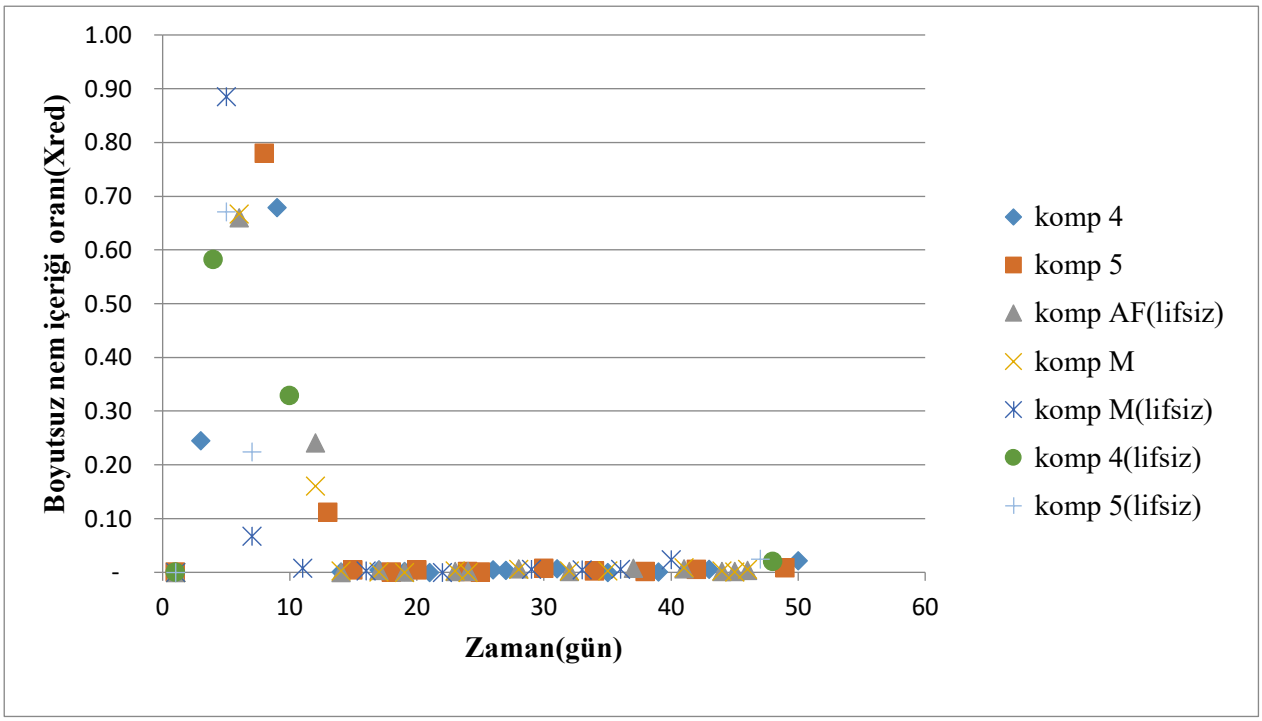
Böylece, etkin nem difüzyon katsayısı (Dw), iki farklı zaman periyodu için Denklem (5) ve (7)'den hesaplanır, ancak Fick'in ikinci yasası hidrasyon ve karbonatlaşma reaksiyonlarının etkilerini ve kenarlar boyunca difüzyonu göz ardı eder (Colinart ve ark., 2012).

BULGULAR ve TARTIŞMA

Önce, yüksek yoğunluğa sahip AF ve M kompozisyonları üretildi, daha sonra çok düşük yoğunluklu 4 ve 5 numaralı kenevir beton kompozisyonları üretilerek, bu kompozisyonlar kenevir saplarına ek olarak kenevir lifleri ilavesi ile de tekrarlandı. Daha sonra ise, yine kompozisyon M kenevir saplarının yanında kenevir liflerini de ilave ederek tekrar hazırlandı ve orta yoğunlukta bir kenevir-beton kompozisyonu elde edildi.
Yedi adet kenevir-beton kompozisyonunun kuruma hızlarının zamana göre değişimi Şekil 1'de görülmektedir.

Şekil 1. 7 farklı kenevir-beton kompozisyonu için kuruma hızının zamanla değişimi

Kompozisyon AF ve lifli M, ilk 10 gün boyunca sırasıyla 11,03 g/m²-saat ve 7,756 g/m²-saat kurutma hızlarına sahipti. Daha sonra, bu hız 14. günde ve 24. günün sonunda sırasıyla 2,883 g/m²-saat ve 1,342 g/m²-saate düştü. Elde edilen kurutma hızları, kompozisyon AF ve lifli M için sırasıyla 0,1 g/m²-saat ve 0,0531 g/m²-saat idi. İki bileşimin karşılaştırılması, liflerin daha düşük su emme kapasiteleri nedeniyle kuruma hızını düşürdüğünü göstermektedir (Brzyski ve ark., 2020). Ancak, kompozisyon M'nin ilk 9 gün boyunca kuruma hızı 11,267 g/m²-saat iken, kompozisyon 4 için bu hız 6. ve 9. günlerde sırasıyla 17,404 g/m²-saat ve kompozisyon 5 için 14,560 g/m²-saat olmuştur. Kuruma hızı, 12 günün sonunda kompozisyon M ve 5 için sırasıyla 0,1014 g/m²-saat ve 14,590 g/m²-saat olmuştur. Daha sonra, bu hız 19 günün sonunda kompozisyon 4 için 3,39 g/m²-saate düşmüştür. 12 günün sonunda kompozisyon 5'in kuruma hızındaki artış, yüksek miktarda serbest suyun uzaklaştırılması ve suyun yüzeye olan buharlaşma hızının difüzyon hızına göre düşük olması ile açıklanabilir (Colinart ve ark., 2012). Lifli 4 ve 5 numaralı kompozisyonların 13 günlük kuruma hızları 9,326 g/m²-saat ve 11,68 g/m²-saat olmuştur. 31 ve 34 gün sonra, bu hızlar lifli 4 ve 5 numaralı kompozisyonlar için sırasıyla 0,0163 g/m²-saat ve 0,119 g/m²-saat'e düşmüştür. Bu sonuç, kenevir liflerinin düşük su geçirgenliği nedeniyle liflerin kuruma hızı üzerindeki azaltıcı etkisini de desteklemektedir (Brzyski ve ark., 2020). Malzemenin bağıl nemi ortamla dengelenene kadar kürlenme odası ortamında küçük pozitif ve negatif ağırlık farklılıkları da gözlemlenmiştir.
Kompozisyonların etkin nem difüzyon katsayıları Tablo 1'de verilmiştir.



Tablo 1. Hazırlanan kenevir-beton kompozisyonlarının başlangıçtaki su içeriği, kuruma süresi, kuru yoğunluk ve etkin nem difuzyon katsayıları

Kenevir-beton kompozisyonları	X_0(gH_2O $gkuru^{-1}$)	Kuruma süresi (gün)	Kuru yoğunluk (kgm^{-3})	10^7Dw(Etkin difüzyon katsayısı) ($m^2\ s^{-1}$) (Den(5))	10^7Dw(Etkin difüzyon katsayısı) ($m^2\ s^{-1}$) (Den (7))	Thava(^{0}C), Bağıl rutubet(%)
AF	1	24	351	3.08	0.417	16.4-19.4^{0}C,29-34%
M	0.923	37	408	1.15	0.413	18.9-22^{0}C, 30-45%
4	0.933	31	156	1.17	0.543	18.9-22^{0}C, 30-45%
5	1.174	34	160	2.31	1.8	18.9-22^{0}C, 30-45%
4 lifli	0.933	38	160	7.25	1.14	16.4-21.3^{0}C,30-45%
5 lifli	1.174	48	192	6.39	3.46	16.4-21.3^{0}C,30-45%
M lifli	0.923	45	283	3.38	8.06	16.4-19.4^{0}C,29-34%

%50 su içeriğine sahip AF kompozisyonu, düşük hava nemine bağlı olarak, kompozisyonun iç kısmındaki tam buharlaşma nedeniyle kısa bir süre sonra 3,08*10^{-7} m^2/s nem difüzyon katsayısına sahipti. Uzun bir difüzyon süresinden sonra nem difüzyon katsayısı 0,417*10^{-7} m^2/s'ye düştü. %48 ve %48,25 su içeriğine sahip M ve 4 kompozisyonları, kısa bir süre sonra sırasıyla 1,15*10^{-7} m^2/s ve 1,17*10^{-7} m^2/s nem difüzyon katsayılarına ve uzun bir difüzyon süresinden sonra sırasıyla 0,413*10^{-7} m^2/s ve 0,543*10^{-7} m^2/s nem difüzyon katsayılarına sahipti; bunun nedeni, M ve 4 kompozisyonlarındaki havanın bağıl neminin AF kompozisyonundan daha yüksek olmasıdır. %54 su içeren 5 numaralı kompozisyonun nem difüzyon katsayıları, kısa ve uzun difüzyon sürelerinden sonra sırasıyla 2,31*10^{-7} m^2/s ve 1,8*10^{-7} m^2/s idi. Bu değişim, daha yüksek su içeriği, nem geçirgenliğindeki fark ve AF kompozisyonuna göre biraz daha yüksek bağıl nem nedeniyle daha düşük bir buharlaşma hızı olarak ifade edilebilir (Collet ve ark., 2013).

Lifli 4 ve 5 numaralı kompozisyonlarının kısa bir süre sonra nem difüzyon katsayıları 7,25*10^{-7} m^2/s ve 6,39*10^{-7} m^2/s iken, uzun bir difüzyon süresinden sonra nem difüzyon katsayıları sırasıyla 1,14*10^{-7} m^2/s ve 3,46*10^{-7} m^2/s'ye düştü. Uzun bir difüzyon süresinden sonra nem difüzyon katsayılarında bir azalma elde edilmesine rağmen, diğer kompozisyonlardan daha yüksek nem difüzyon katsayıları gözlendi. Bu daha yüksek nem difüzyon katsayıları, gözeneklere bağlı olarak liflerin su alma yeteneğine sahip olmasından kaynaklanmaktadır (Sair ve ark., 2018). Lifli M kompozisyonu, kısa ve uzun difüzyon sürelerinde sırasıyla 3,38*10^{-7} m^2/s ve 8,06*10^{-7} m^2/s nem difüzyon katsayılarına sahipti. Diğer kompozisyonların aksine, lif etkisinden dolayı elde edilen daha yüksek katsayılara rağmen nem difüzyon katsayısı artmaktadır. Bu durum, yüksek su içeriğine sahip kenevir parçacıkları ve lifler arasında bulunan makro gözeneklere bağlı nem geçirgenliği farkıyla açıklanabilir. Bağlayıcı içinde bulunan mikro gözeneklerin geçirgenlik üzerinde daha küçük bir etkisi olmuştur (Collet ve ark., 2013), (Walker ve Pavía, 2014), (Jiang ve ark., 2017), (Delannoy ve ark., 2020), (Delannoy ve ark., 2018). Kürlenme ve kuruma süreleri, su içeriği, kenevir ve lif etkilerini içeren kompozisyon türüne göre değişmekle birlikte, Tablo 1'den görüldüğü üzere genellikle 24 ila 48 gün arasında değişmektedir. Kalıplanmış bloklar için yalnızca numunenin üst yüzeyinden kuruma işleminin 80-100 gün sonra tamamlandığı bildirilmektedir (Colinart ve ark., 2012). Ancak bu çalışmada, kuruma alt yüzey hariç tüm yüzeylerde gerçekleşmiştir. Bu nedenle kuruma süreleri kısa olmuş ve (Colinart ve ark., 2012)'deki çalışma ile karşılaştırıldığında daha yüksek nem difüzyon katsayıları da bulunmuştur. (Colinart ve ark., 2012) kısa ve uzun difüzyon sürelerinde benzer nem difüzyon katsayıları elde etmiş olsa da, lifli M kompozisyonu hariç, bu çalışmada hesaplamalar uzun difüzyon sürelerinde daha düşük nem difüzyon katsayılarını vermektedir. Bu durum, kompozisyonların iç kısımlarında buharlaşmanın, havaya maruz kalan daha yüksek yüzey alanları nedeniyle kısa sürede tamamlanmasıyla açıklanabilir.

Yedi kenevir-beton karışımının boyutsuz nem oranı (Xred) değerlerinin zamana göre değişimi Şekil 2'de verilmiştir.

Şekil 2. 7 kenevir-beton kompozisyonu için boyutsuz nem içeriği oranının (Xred) zamanla değişimi

Bu değişime göre, AF ve M kompozisyonlarının yoğunluğu yaklaşık 701 kg/m^3 ila 351 kg/m^3 ve 500 kg/m^3 ila 408 kg/m^3 arasında değişmiştir, kompozisyon 4 ve 5'in yoğunluğu ise kürlenme süresi boyunca sırasıyla 348 kg/m^3'ten 156 kg/m^3'e ve 308 kg/m^3'ten 160 kg/m^3'e değişmiştir. Bununla birlikte, lif içeren 4 ve 5 kompozisyonlarının yoğunluk değişimleri 315 kg/m^3 ila 160 kg/m^3 ve 280 kg/m^3 ila 192 kg/m^3 arasında, lif içeren M kompozisyonunun yoğunluk değişimleri ise yine Tablo 1'den görüldüğü üzere kompozisyonların kuru yoğunluklarına göre sırasıyla 507 kg/m^3 ila 283 kg/m^3 arasındadır.

SONUÇ

• Lifli kompozisyonlarda kuruma hızının lifsiz kompozisyonlara göre daha düşük olduğu görülmektedir.

• Kürlenme ve kuruma süreleri, su içeriği, kenevir ve lif etkilerini içeren kompozisyon türüne göre değişmektedir.

•Lifli M kompozisyonu hariç, hesaplamalar uzun difüzyon sürelerinde kısa difüzyon sürelerinden daha düşük nem difüzyon katsayıları vermiştir.

Abstract

The occurrence of micropollutants such as pesticides and pharmaceuticals in aquatic environments has raised significant environmental and public health concerns. Conventional water and wastewater treatment processes are often insufficient for the complete elimination of these contaminants; therefore, alternative methods are required. Granular activated carbon (GAC) adsorption has emerged as an effective method due to the high surface area and strong affinity of activated carbon for diverse organic compounds. In this study, the application of GAC from water and wastewater was investigated for the removal of pesticides and pharmaceuticals, respectively. Results indicate that GAC demonstrates high adsorption efficiency, suggesting its potential as a reliable method for micropollutant removal. Previous studies in the literature also support that high removal efficiencies can be achieved by GAC, depending on operational conditions such as contact time, adsorbent dose, and initial contaminant concentration. The findings highlight that GAC adsorption is a practical solution for enhancing water quality in terms of emerging contaminants removal.

Keywords: Granular activated carbon, Micropollutants, Pesticides, Pharmaceuticals, Water treatment, Wastewater treatment

INTRODUCTION

Pollutants which are present in the concentration range of µg/L to ng/L in the environment are referred to as micropollutants. Nowadays, many pesticides and pharmaceuticals are detected as micropollutants in the influent of drinking water treatment plants and wastewater treatment plants (WWTPs), respectively. These micropollutants are known to have negative impacts on the environment despite the very low concentrations (Çeçen and Aktaş, 2011; Jatoi et al., 2021, Rattier et al., 2012; Sishu et al., 2022; Stehle and Schulz, 2015; Xu and Duran, 2017). Since many of conventional drinking water and wastewater treatment plants are not designed for micropollutant removal, they cannot be removed completely and may pose risk to human health.

Conventional water and wastewater treatment systems are designed to eliminate several types of contaminants from water. These include colloidal particles, dissolved salts, harmful microorganisms, biodegradable carbon, nitrogen and phosphorus. Their capacity to eliminate micropollutants is, nevertheless, quite variable and restricted. The difficulty in developing tailored treatment technologies stems from the extremely low quantities of these pollutants, which frequently go below detection criteria (Nas et al., 2017; Rodriguez-Narvaez et al., 2017; Saravanan et al., 2021; Teodosiu et al., 2018; Verlicchi et al., 2012). The unique chemical characteristics of the compounds, the treatment methods employed, and the system's operating settings all significantly impact how well micropollutants are removed from the environment. Important factors affecting removal effectiveness are the micropollutants' molecular structure, polarity, solubility, and persistence (Luo et al., 2014).

There are many methods used for micropollutant removal including coagulation-flocculation, ozonation, advanced oxidation, membrane filtration, biodegradation and activated carbon adsorption (Borrull et al., 2021; Nas et al., 2017; Saravanan et al., 2021; Tröger et al., 2017). However, implementing these technologies in large-scale treatment facilities presents several challenges, primarily related to cost-effectiveness, energy consumption, and operational complexity (Ibrahim et al., 2023). Among these various advanced treatment processes, adsorption is considered the most commonly used method because of its cost-effectiveness, operational simplicity, and ease of regeneration (Saravanan et al., 2021; Teodosiu et al., 2018). Numerous studies have highlighted that among various adsorbent materials, activated carbon stands out as the most widely utilized and efficient adsorbent for micropollutant removal in water treatment (Rodriguez-Narvaez et al., 2017; Sangkarak et al., 2020; Sophia & Lima, 2018; Teodosiu et al., 2018; Zhao et al., 2022). This technology has

shown promise in effectively removing a wide range of micropollutants without the associated high operational costs of other advanced treatment methods. However, further research is required to optimize its application in large-scale water treatment facilities and to assess its long-term efficiency in micropollutant removal (Tröger et al., 2020). The purpose of this research was to investigate the use of granular activated carbon (GAC) for the removal of pesticides and pharmaceuticals from water and wastewater, respectively.

Activated Carbon

Activated carbon is the most widely used adsorbent in water and wastewater treatment. The ability to adsorb a wide variety of organic compounds and its economic feasibility make activated carbon the most preferable. In water treatment, it is used to remove organic compounds that cause odor, taste and color. In advanced wastewater and industrial treatment, it is used to remove toxic organic compounds. It is generally used in the granular form in a carbon adsorption column in water and wastewater purification (Hung et al., 2005).

Activated carbon is a porous carbon material with a high adsorption capacity because of its high surface area (between 500 and 1500 m^2/g). Due to this, the amount of material adsorbed is potentially very large. The total surface available for adsorption of solute includes the external surface of the particles and the surfaces of pores. The pore surface area is much larger than the external surface area of the particles. Therefore, adsorption occurs on the pores' surfaces mostly. The ratio of the total surface area to the mass of activated carbon is very large. As a result, activated carbon adsorption can be used in tertiary treatment for the removal of organic pollutants from the secondary effluent of biological wastewater treatment systems. It can be produced from many different carbonaceous materials, such as coal, lignite, wood, coconut shell and some polymers (Çeçen, 2024; Çeçen and Aktaş, 2011; Hung et al., 2005; Junpirom, 2006).

Activated carbon is mainly in the form of powdered activated carbon (PAC) and granular activated carbon (GAC). The average particle size of PAC is in the range of 15-25 μm. It is applied for the treatment of both wastewater and drinking water. GAC is generally in the form of crushed granules of shell or coal and has sizes ranging from 0.2 to 5 mm. GAC filters are widely used for drinking water, groundwater and wastewater purification and removal of toxic organic compounds. In some GAC applications, a microbiological film may form on the particles. As a result, biological removal of contaminants is combined with GAC adsorption. The new material is called as biological activated carbon (BAC) (Çeçen and Aktaş, 2011).

The use of activated carbon, either as GAC or PAC has been investigated in many studies. The use of activated carbon is a widespread technology that has been applied for many years to remove pollutants from water and wastewater. Thus, significant knowledge on setup and operation of such systems is available. The main advantage of using activated carbon is the effective removal of micropollutants, also no by-products are generated (Baresel et al., 2019).

Pesticides Removal from Drinking Water by GAC

Conventional water treatment processes often demonstrate inadequate efficiency in completely removing pesticides (Jatoi et al., 2021). Hence, alternative treatment methods have been used for effective elimination of pesticides from drinking water.

In a study, batch tests were carried out to investigate the adsorption of a pesticide (malathion) by GAC from agricultural runoff. In these tests, two types of GAC were used for comparing the effectiveness. The results indicated that granular activated carbon could be used to effectively adsorb malathion from agricultural runoff (Jusoh et al., 2011). Also, another study investigated the use of two different granular activated carbons Filtrasorb 400 and Norit 1240 for removal of pesticides from water. It was shown that the efficiency of Norit 1240 ranged between 5-32%, while the efficiency of Filtrasorb F400 was higher that ranged between 12-64% depending on the contact time. It was also indicated that pH of water and the initial concentrations of the pesticides affected the adsorption efficiency (%) and adsorption capacity (μg/g) (Ilavsky et al., 2021).

Beyond simple adsorption, the synergistic potential of combining physical and biological mechanisms has been validated in operational treatment plants. For instance, a study conducted at the Shiraz treatment plant compared granular activated carbon (GAC) and biological activated carbon (BAC) systems for removing 18 pesticides from water, finding that BAC consistently outperformed GAC due to the synergistic effects of adsorption and biodegradation. BAC achieved 100% removal of seven pesticides including methyl parathion and malathion, while GAC showed lower efficiency (e.g., 67.38% vs. 100% for methyl parathion). This research demonstrates

that BAC systems offer a highly effective supplementary treatment option for municipal water facilities dealing with pesticide contamination (Tahmasebi et al., 2023).

In addition to biological integration, enhancing GAC filtration with advanced oxidation processes such as ozonation has proven highly effective for contaminant removal. Combining ozonation with granular activated carbon (GAC) filtration effectively removes pesticides and their transformation products from drinking water, achieving over 90% removal rates while reducing toxicity. Although ozonation degrades pesticides within 10-15 minutes, it can produce toxic byproducts, which are subsequently eliminated in the GAC filtration step. Furthermore, the research emphasizes that GAC performance declines significantly after 7-9 years of use, recommending replacement every two years to maintain water safety and treatment effectiveness (Shi et al., 2025).

Pharmaceuticals Removal from Wastewater by GAC

As mentioned before, conventional wastewater treatment systems are not designed for micropollutant removal. In traditional treatment, the majority of micropollutants cannot be eliminated and remain in the effluent. Therefore, it becomes essential to use new and advanced methods that can eliminate micropollutants from wastewater (Balu et al., 2024; Belete et al., 2023).

Removal of pharmaceuticals from wastewater by granular activated carbon was investigated in many studies. In a study, pharmaceutical removal in effluents from three WWTP was searched. The aim was to achieve 95% removal of selected micropollutants in a Swedish WWTP through adsorption onto activated carbon and to compare the performance of PAC and GAC. Results showed that activated carbon is an efficient method to remove pharmaceuticals from WWTP effluents. 95% removal was achieved for almost all the targeted micropollutants. Results demonstrated that there is 95% removal if PAC was applied at a dose of 15-20 mg/L, and more than 90% removal if GAC was used for all tested micropollutants (Karelid et al., 2017).

In another study, a full-scale GAC system was used to remove steroidal estrogens and pharmaceuticals from the WWTP effluent. Results showed that there was more than 43% to 64% reduction in steroidal estrogens. Additionally, many of the targeted pharmaceuticals, such as mebeverine, were removed between 84-99%. However, it is stated that some of the pharmaceuticals including carbamazepine and propranolol had removal efficiencies of 17-23%. It is said that removal of some organic micropollutants with GAC-based technology is less efficient, because adsorption sites become saturated as time passes (Grover et al., 2011).

Additionally, recent studies have shown that hybrid treatment schemes combining membrane-based separation, such as ultrafiltration in membrane bioreactors, with biologically active granular activated carbon (GAC) filtration can achieve highly efficient removal of a broad range of organic micropollutants from municipal wastewater. Pilot-scale evaluations report that coupling physical filtration with adsorption and biodegradation consistently reduces pharmaceuticals and other trace contaminants to very low or non-detectable concentrations, demonstrating a synergistic effect between membrane retention and bio-active carbon surfaces (Baresel et al., 2019).

Alternative advanced wastewater treatment technologies have also been systematically compared to carbon-based processes. Large-scale pilot trials contrasting ozonation with powdered activated carbon (PAC) treatment have demonstrated that both approaches consistently remove a broad suite of contaminants—often exceeding 80% removal of monitored micropollutants—while improving effluent toxicity profiles, with PAC sometimes providing broader removal due to the absence of oxidation by-product formation (Margot et al., 2013).

Recent studies also highlight the importance of synergistic interactions between adsorption and biodegradation within GAC filters, where microbial transformation processes can extend carbon lifespan and alter removal pathways. In a study the interaction of adsorption and biodegradation in the removal of organic micropollutants in GAC filters was investigated. By comparing GAC with non-adsorbing sand media, it was shown that adsorption can effectively extend the residence time of micropollutants, thereby enhancing biodegradation—particularly for moderately adsorbable and biodegradable substances such as diclofenac. In contrast, weakly adsorbable compounds (e.g., N-Nitrosodimethylamine) exhibited strong dependence on contact time, while biologically recalcitrant but strongly adsorbable substances (e.g., carbamazepine) were primarily retained through the adsorption–desorption cycling rather than degradation. Overall, the study demonstrates that adsorption and biodegradation are closely coupled processes in GAC filters, influencing removal efficiencies and complicating the interpretation of filter performance (Betsholtz et al., 2024).

CONCLUSION

This study summarizes the use of granular activated carbon for micropollutant removal from drinking water and wastewater. For water treatment, pesticides removal, for wastewater treatment pharmaceuticals removal was investigated. Studies showed that the use of GAC is a very effective and well-known method for removal of many micropollutants from water and wastewater. The adsorption potential of micropollutants on GAC is relatively high which makes it preferable for treatment purposes. However, its effectiveness depends on different conditions such as careful design of filters, proper operation and monitoring. It is effectively used in advanced treatment and studies continue for improving its performance and cost-effectiveness.

Özet

Bu çalışmada, guanidinyum oktahidrotriborat ($GuaB_3H_8$) iyonik sıvısının geometrik ve elektronik özellikleri yoğunluk fonksiyoneli teorisi (DFT) kullanılarak ayrıntılı olarak incelenmiştir. Gaussian 16 program paketi ile B3LYP/6-311++G(d,p) ve ωB97X-D/6-311++G(d,p) teori düzeylerinde, guanidinyum katyonu (Gua^+), oktahidrotriborat anyonu ($B_3H_8^-$) ve bunlardan oluşan iyonik sıvının geometri optimizasyonları gerçekleştirilmiş, harmonik frekans analizleriyle tüm yapıların potansiyel enerji yüzeyinde yerel minimumda olduğu doğrulanmıştır. Her iki fonksiyonel de C–N, N–H, B–H ve B–B bağ uzunlukları için birbirine oldukça yakın değerler vermiş; bağ parametrelerindeki küçük farklar, seçilen yöntem–baz seti kombinasyonunun yapısal eğilimleri güvenilir biçimde tanımladığını göstermiştir. İyonik sıvının bağlanma enerjileri B3LYP ve ωB97X-D için sırasıyla −172.5 ve −177.1 kcal/mol olarak hesaplanmış, bu da güçlü katyon–anyon etkileşimleri ile yüksek termodinamik kararlılığı ortaya koymuştur. Frontier moleküler orbital analizi, HOMO'nun hidrojence zengin $B_3H_8^-$ birimi üzerinde, LUMO'nun ise kısmen guanidinyum katyonu üzerinde lokalize olduğunu göstermiş; HOMO–LUMO enerji aralığının B3LYP için 4.92 eV, ωB97X-D için 8.43 eV olarak bulunması, sistemin elektronik açıdan kararlı doğasını desteklemiştir. Moleküler elektrostatik potansiyel (MEP) haritaları, beklenen yük ayrımını ve belirgin yük lokalizasyonunu doğrulayarak elde edilen bağlanma enerjileri ve orbital bulgularıyla tutarlı bir tablo sunmuştur. Elde edilen sonuçlar, $GuaB_3H_8$ iyonik sıvısı boran temelli sistemlerin yüksek kararlılık sunduğunu ve benzer sistemlerin rasyonel tasarımı için önemli yapısal ve elektronik parametreler sağladığını göstermektedir.

Anahtar Kelimeler: Guanidinyum oktahidrotriborat, iyonik sıvı, yoğunluk fonksiyoneli teorisi, HOMO–LUMO

Computational characterization of the structural and electronic properties of guanidinium octahydrotriborate as a potential hydrogen storage ionic liquid

Abstract

In this study, the geometric and electronic properties of the guanidinium octahydrotriborate ($GuaB_3H_8$) ionic liquid were examined in detail using density functional theory (DFT). Geometry optimizations of the guanidinium cation (Gua^+), the octahydrotriborate anion ($B_3H_8^-$), and the ionic liquid formed by these species were performed at the B3LYP/6-311++G(d,p) and ωB97X-D/6-311++G(d,p) levels of theory with the Gaussian 16 program package, and harmonic frequency analyses confirmed that all structures correspond to local minima on the potential energy surface. Both functionals yielded highly similar values for the C–N, N–H, B–H, and B–B bond lengths; the small differences in bonding parameters indicate that the chosen method–basis set combinations reliably describe the structural characteristics of the system. The binding energies of the ionic liquid were calculated as −172.5 and −177.1 kcal/mol for B3LYP and ωB97X-D, respectively, revealing strong cation–anion interactions and high thermodynamic stability. Frontier molecular orbital analysis showed that the HOMO is localized on the hydrogen-rich $B_3H_8^-$ unit, while the LUMO is partially localized on the guanidinium cation; the HOMO–LUMO gaps, found to be 4.9151 eV for B3LYP and 8.4296 eV for ωB97X-D, further support the electronically stable nature of the system. Molecular electrostatic potential (MEP) maps confirmed the expected charge separation and pronounced charge localization, presenting a picture consistent with the obtained binding energies and orbital findings. Overall, the results demonstrate that the $GuaB_3H_8$ ionic liquid offers high stability among borane-based systems and provides important structural and electronic parameters for the rational design of related materials.

Keywords: Guanidinium octahydrotriborate, ionic liquid, density functional theory, HOMO–LUMO.

GİRİŞ

Küresel enerji talebinin sürekli artması ve fosil yakıtların çevresel etkileri, temiz ve sürdürülebilir enerji kaynaklarına yönelik araştırmaları zorunlu kılmaktadır. Hidrojen, yüksek enerji yoğunluğu ve çevre dostu yanma ürünleri nedeniyle geleceğin ideal enerji taşıyıcısı olarak görülmekte, ancak güvenli ve verimli depolama sorunu yaygın kullanımını engelleyen başlıca zorluklardan birini oluşturmaktadır. ABD Enerji Bakanlığı (DOE) tarafından belirlenen teknik hedefler, hafif ticari araçlarda kullanılmak üzere 5.5 wt% sistem gravimetrik kapasite ve 40 g/L sistem volumetrik kapasite gibi katı kriterler öne sürmektedir (Kohani ve ark.,2023; Liu ve ark., 2023; Chen ve ark., 2023). Boran tabanlı yapılar düşük molekül ağırlığı ile malzemelerin teorik kapasitelerini artırırken, termodinamik ve kinetik sorunların aşılması için rasyonel moleküler tasarımlar gerekmektedir. Son yıllarda iyonik sıvıların düşük buhar basıncı, geniş sıvı aralığı ve yapısal esneklik vb. benzersiz özellikleri uygulamalara yeni bir yaklaşımlar sunmaktadır (Chen ve ark, 2015). Bu bağlamda guanidinyum oktahidrotriborat ($GuaB_3H_8$), hem boran temelli yapısı hem de protonik karakteri nedeniyle gelecek vaat eden bir aday olarak ortaya çıkmıştır (Chen ve ark, 2015). Chen ve ark. 2015'teki çalışması, bu iyonik sıvının %13.8 teorik hidrojen içeriğine sahip olduğunu göstererek bu alandaki ilgiyi artırmıştır. Guanidinyum katyonunun yüksek termal kararlığı ile oktahidrotriborat anyonunun zengin hidrojen kimyasının sinerjik etkileşimi, bu malzemenin hem sistem hedeflerini karşılama hem de döngüsel kullanım için gerekli kararlılığı sağlama potansiyelini güçlendirmektedir (Doroodian ve ark., 2010).

Oktahidrotriborat anyonu ($[B_3H_8]^-$), boran kimyasının temel yapı taşlarından biri olup üç bor atomunun sekiz terminal hidrojenle çevrili dinamik bir yapısı vardır. Bu anyon, katı hal NMR ve nötron kırınımıyla ölçülen molekül içi hareketli davranışıyla tanınır; son yıllarda anharmonik YFT hesaplamaları overton ve kombinasyon bantlarının önemli yoğunluklara sahip olduğunu göstermiştir (Frisch ve ark., 2016). Bykov ve Zhizhin'in kapsamlı derlemesi, $[B_3H_8]^-$ anyonunun organometalik komplekslerdeki koordinasyon kimyası, tuzlarındaki reorientasyonel dinamik ve termo-elektrokimyasal kararlılığını detaylandırarak, $GuaB_3H_8$ gibi iyonik sıvıların moleküler düzeyde anlaşılması için teorik yöntemlerin gerekliliğini vurgulamaktadır (Bykov &Zhizhin, 2019; Zheng ve ark., 2019).

Özellikle Gaussian 16 yazılımı, geniş fonksiyonel ve baz seti seçenekleri sayesinde iyonik sıvılar gibi çok merkezli etkileşimlere sahip sistemlerin doğru modellenmesine olanak tanımaktadır (Frisch ve ark., 2016). İyonik sıvıların karmaşık elektronik yapısını tanımlamada yaygın B3LYP fonksiyonelinin yanı sıra uzun menzilli dispersiyon etkileşimlerini açıkça hesaba katan ωB97X-D fonksiyoneli de sıklıkla tercih edilmektedir (Chai & Head-Gordon, 2008; Rekken & Krossing, 2016). Literatürde yapılan sistematik karşılaştırmalar, iyon-çiftlerinin geometri optimizasyonu ve elektronik enerji hesaplamalarında bu iki fonksiyonelin güvenilir bir performans sağladığını göstermektedir. Ayrıca 6-311++G(d,p) gibi difüz ve polarizasyon fonksiyonları içeren baz setlerinin hidrojen bağlanma enerjilerinin ve frontier moleküler orbitallerin doğru tanımlanması için kritik olduğu çeşitli hesaplamalı çalışmalar tarafından desteklenmektedir (Hehre ve ark., 1986; Rekken & Krossing, 2016).

Bu çalışma, guanidinyum oktahidrotriborat iyonik sıvısının yapısal ve elektronik özelliklerini B3LYP ve ωB97X-D fonksiyonelleri ile 6-311++G(d,p) baz seti kullanarak kapsamlı olarak incelemeyi amaçlamaktadır. Optimize edilmiş geometriler üzerinden bağ uzunlukları, enerji parametreleri ve temel yapısal özellikler analiz edilecek; HOMO-LUMO enerji aralıkları, moleküler elektrostatik potansiyel (MEP) yüzeyleri haritaları hesaplanarak molekülün geometrik ve elektronik özellikleri ortaya çıkarılacaktır (Frisch ve ark., 2016; Ramkumar & Gardas, 2019). Elde edilecek bulguların, sürdürülebilir enerji depolama teknolojilerinde kullanılabilecek rasyonel moleküler tasarım stratejilerine katkı sunması ve guanidinyum oktahidrotriborat iyonik sıvısının hidrojen depolama özelliklerinin ortaya koymasında ilk basamak olması hedeflenmektedir (Chen ve ark. 2015). Bu sayede $GuaB_3H_8$'in yapısal dinamikleri ve enerjiye dayalı özelliklerine ilişkin kritik bilgilerin, literatürdeki artan ilgiye dikkate değer bir katkı sağlaması beklenmektedir.

MATERYAL VE METOT

Guanidinyum oktahidrotriborat iyonik sıvısı ($CN_3H_6^+$ katyonu ve $[B_3H_8]^-$ anyonu), yoğunluk fonksiyoneli teorisi (DFT) tabanlı hesaplamalar kullanılarak ayrıntılı biçimde incelenmiştir. Bileşen katyon ve anyon yapılarının yanı sıra iyon çiftinin tamamı, hem geometrik hem de elektronik özelliklerin güvenilir biçimde tanımlanabilmesi amacıyla B3LYP ve ωB97X-D fonksiyonelleri ile optimize edilmiştir. B3LYP, yaygın

kullanılan hibrit değiş-tokuş–korelasyon fonksiyoneli olup temel yapısal özelliklerin tutarlı biçimde elde edilmesinde etkilidir; ωB97X-D ise uzun menzilli etkileşimleri ve dispersiyon kuvvetlerini daha doğru temsil eden menzil ayrımlı hibrit fonksiyonel olması nedeniyle özellikle iyonik sıvıların modellemesinde tercih edilmiştir. Tüm hesaplamalarda temel fonksiyonlar olarak polarizasyon ve difüz fonksiyonlar içeren 6-311++G(d,p) baz seti kullanılmıştır.

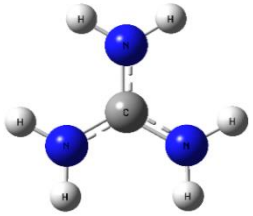
İyonik sıvı için B3LYP/6-311++G(d,p) ve ωB97X-D/6-311++G(d,p) teori düzeylerinde çeşitli başlangıç geometrilerinden hareketle geometri optimizasyonları gerçekleştirilmiş ve her iki fonksiyonel için de en düşük elektronik enerjiye sahip iyonik sıvı yapısı belirlenmiştir. Optimizasyon sonrasında elde edilen bu yapıların potansiyel enerji yüzeyinde gerçek bir yerel minimuma karşılık gelip gelmediğini doğrulamak amacıyla harmonik frekans analizleri yapılmış; hiçbir sanal frekansın bulunmaması, hesaplanan iyonik sıvı geometrilerinin yerel minimum niteliğini açıkça teyit etmiştir.

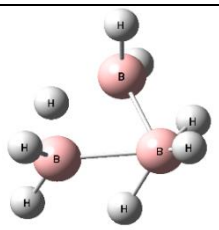
Guanidinyum oktahidrotriborat sisteminin bağlanma enerjileri (ΔE_b), iyon çiftinin toplam enerjisi ile bileşen iyonların ayrı ayrı optimize edilmiş minimum enerji değerleri kullanılarak hesaplanmıştır. Bağlanma enerjisi, Denklem (1) uyarınca:

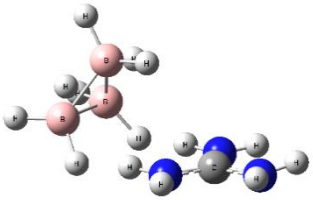
$$\Delta E_b = E_{İS} - (E_{katyon} + E_{anyon}) \quad (1)$$

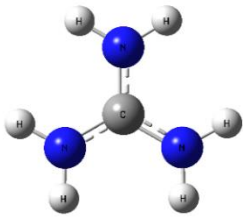
Burada $E_{İS}$ iyonik sıvının optimize edilmiş geometrideki toplam elektronik enerjisini; E_{katyon} ve E_{anyon} ise sırasıyla guanidinyum katyonu ve oktahidrotriborat anyonunun bağımsız olarak optimize edilmiş minimum enerji değerlerini ifade etmektedir. Bu yaklaşım, iyon çiftindeki elektrostatik, kovalent ve dispersiyon kaynaklı etkileşimlerin toplam enerjisel katkıları hakkında nicel bilgi sunmakta ve sistemin kararlılık değerlendirmelerine temel oluşturmaktadır.

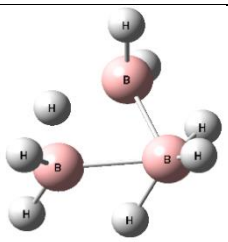
Bağlanma enerjisi hesaplamalarında Counterpoise (CP) düzeltmesi kullanılmamıştır. BSSE düzeltmesi, etkileşim enerjisinin küçük olduğu (örneğin nötr moleküller arası zayıf hidrojen bağları veya dispersiyon etkileşimleri) sistemlerde sonuçları nitel olarak değiştirebilmektedir. Ancak GuaB3H8 gibi iyonik sıvılarda bağlanma enerjisi temel olarak güçlü elektrostatik etkileşimlerden kaynaklanmakta ve oldukça yüksek değerlere (bu çalışmada ~ -175 kcal/mol) ulaşmaktadır. Bu büyüklükteki bir enerji değişiminde, BSSE kaynaklı oluşabilecek birkaç kcal/mol'lük sapma, toplam enerjinin çok küçük bir yüzdesine (%1-2 civarı) tekabül ettiğinden ihmal edilmiştir.

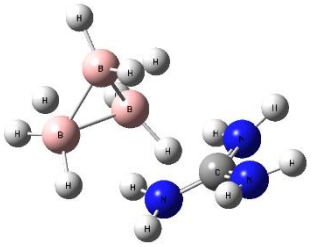












Elektronik özelliklerin ayrıntılı incelemesinde frontier moleküler orbitalleri (HOMO–LUMO), MEP (moleküler elektrostatik potansiyel) yüzeyleri elde edilmiş; tüm hesaplamalar 0 K'de elektronik enerjileri ile raporlanmıştır.

BULGULAR ve TARTIŞMA

Geometrik Yapı ve Bağlanma Enerjileri

Guanidinyum katyonu (Gua^+), oktahidrotriborat anyonu ($B_3H_8^-$) ve bunlardan oluşan iyonik yapının ($GuaB_3H_8$) kararlı geometrileri B3LYP/6-311++G(d,p) ve ωB97X-D/6-311++G(d,p) düzeylerinde optimize edilmiştir. Elde edilen yapılar Tablo 1'de, seçilmiş bağ uzunlukları, bağ açıları ve toplam enerjiler ise Tablo 2'de özetlenmektedir. Her iki fonksiyonel ile bulunan C–N, N–H, B–H ve B–B bağ uzunlukları birbirine oldukça yakın olup, farkların genel olarak 0.01–0.02 Å mertebesinde olduğu görülmektedir. Bu durum, kullanılan fonksiyonellerin geometri tahminleri açısından tutarlı ve güvenilir olduğunu göstermektedir.

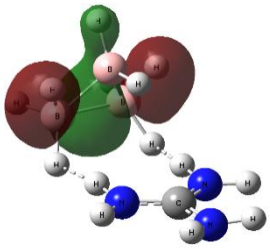
Tablo 1. İyonik Sıvının Kararlı Geometrileri

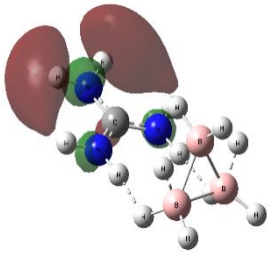
Yöntem	Gua^+	$B_3H_8^-$	$GuaB_3H_8$
B3LYP/ 6-311++G(dp)			
ωB97X-D/ 6-311++G(dp)			

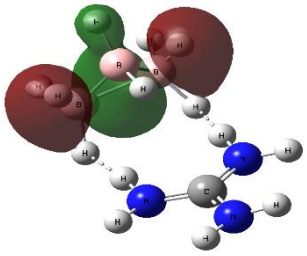
Tablo 2. İyonik sıvının kararlı geometrilerine ait önemli parametreler

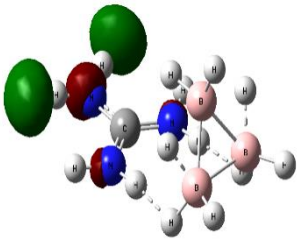
Yöntem	Tür	Bağ Uzunluğu (°A)	Bağ Açıları (^{0}C)	E_0 (au)
B3LYP/6-311++G(d,p)	$GuaB_3H_8$	C-N:1.32 N-H:1.03 B-H:1.21 B-B:1.82	N-C-N:119.68 H-N-H:117.39 H-B-H:112.46	-285.400853
B3LYP/6-311++G(d,p)	Gua^+	N-H:1.00 C-N:1.33	N-C-N:119.99 H-N-H:116.84	-205.835354
B3LYP/6-311++G(d,p)	$B_3H_8^-$	B-H:1.21-1.26 B-B : 1.75-1.82	H-B-H:118.52	-79.290522
ωB97X-D/6-311++G(d,p)	$GuaB_3H_8$	C-N:1.32 N-H:1.03 B-H:1.22 B-B:1.82	N-C-N:119.73 H-N-H:117.50 H-B-H:112.79	-285.306012
ωB97X-D/6-311++G(d,p)	Gua^+	N-H: 1.00 C-N: 1.33	N-C-N:119.99 H-N-H:116.95	-205.767750
ωB97X-D/6-311++G(d,p)	$B_3H_8^-$	B-H: 1.21- 1.26 B-B : 1..75-1.82	H-B-H:117.98	-79.255908

B3LYP/6-311++G(d,p) düzeyinde $GuaB_3H_8$ için C–N bağı yaklaşık 1.32 Å, N–H bağı 1.03 Å, B–H bağları 1.21–1.26 Å ve B–B bağları 1.75–1.82 Å aralığında bulunmuştur. ωB97X-D fonksiyoneli ile elde edilen değerler, küçük sapmalar dışında bu sonuçlarla çakışmakta, özellikle B–B çekirdekleri arasındaki mesafelerin ve B–H bağlarının uzunluk aralığının benzer kaldığı görülmektedir. Bu küçük farklar, fonksiyonellerin değiş-tokuş–korelasyon tanımlarından kaynaklanan beklenen sapmalar olup, yapısal eğilimleri değiştirecek boyutta değildir.









$GuaB_3H_8$ iyonik çiftinin bağlanma enerjileri, kompleksin toplam enerjisi ile katyon ve anyonun ayrı ayrı optimize edilmiş enerjileri kullanılarak hesaplanmıştır. B3LYP/6-311++G(d,p) düzeyinde elde edilen bağlanma enerjisi −172.5 kcal·mol^{-1} iken, dispersiyon düzeltmesi içeren ωB97X-D/6-311++G(d,p) yöntemiyle hesaplanan değer −177.1 kcal·mol^{-1} olarak bulunmuştur. Bu büyüklükteki negatif bağlanma enerjileri, Gua^+ ile $B_3H_8^-$ arasında güçlü elektrostatik çekimlerin yanı sıra belirgin yönlenmiş hidrojen bağlarının varlığına işaret etmekte olup, kompleksin gaz fazında yüksek termodinamik kararlılığa sahip olduğunu göstermektedir.

Uç (Frontier) Moleküler Orbitaller ve HOMO–LUMO Enerji Aralığı

$GuaB_3H_8$ iyonik çiftinin elektronik yapısı, frontier moleküler orbitallerin (HOMO ve LUMO) dağılımı Tablo 3'de ve enerji seviyeleri Tablo 4'de değerlendirilmiştir. B3LYP/6-311++G(d,p) düzeyinde elde edilen HOMO, ağırlıklı olarak $B_3H_8^-$ anyonunun hidrojence zengin terminal B–H bağları üzerinde ve kısmen de anyonun iskelet bölgesinde yoğunlaşmaktadır.

LUMO, katyon–anyon etkileşim bölgesine doğru kısmi lokalizasyon göstermekte ve özellikle guanidinyum katyonu çevresinde yoğunlaşmaktadır. Bu durum, elektron kazanımı veya redüksiyon süreçlerinde katyonun aktif rol oynayabileceğine ve yük transferinin katyonik birim üzerinden tetiklenebileceğine işaret etmektedir.

Tablo 3. Guanidinyum Oktahidrotriborat İyonik Sıvısının ωB97X-D ve B3LYP Yöntemleri ile HOMO, LUMO Dağılımlarının Gösterimi

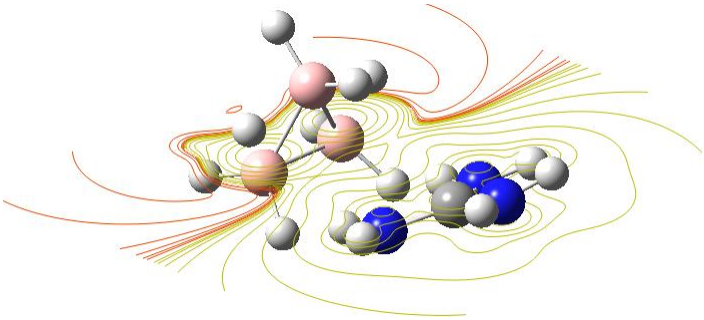
B3LYP/6-311++G(d,p)	–6.6899	–1.7726	4.9151
ωB97X-D/6-311++G(d,p)	–8.5998	–0.1687	8.4296

Enerji seviyeleri Tablo 4'te özetlenmiştir. B3LYP/6-311++G(d,p) düzeyinde HOMO ve LUMO enerji değerleri sırasıyla –6.6899 eV ve –1.7726 eV olup, hesaplanan HOMO–LUMO enerji aralığı (E_{HLG}) 4.9151 eV olarak bulunmuştur. ωB97X-D/6-311++G(d,p) düzeyinde ise HOMO enerjisi –8.5998 eV, LUMO enerjisi –0.1687 eV olup, E_{HLG} değeri 8.4296 eV'a yükselmektedir.

Bu sonuçlar, ωB97X-D fonksiyonelinin, özellikle uzun menzilli etkileşimleri ve dispersiyon kuvvetlerini daha gerçekçi biçimde tanımlaması nedeniyle sistemi elektronik olarak daha "katı" ve geniş bant aralıklı bir yapı olarak modellediğini göstermektedir. Daha geniş HOMO–LUMO aralığı, kinetik kararlılığın artması ve elektronik uyarılma süreçlerinin daha yüksek enerji bariyerleri ile ilişkilendirilmesi açısından önemlidir. Bu bağlamda, B3LYP daha "yumuşak" ve reaktif bir elektronik resim sunarken, ωB97X-D fonksiyoneli $GuaB_3H_8$'i daha kararlı ve elektronik olarak daha az reaktif bir sistem olarak betimlemektedir.



Moleküler Elektrostatik Potansiyel (MEP) Analizi

Moleküler elektrostatik potansiyel (MEP) yüzeyleri, katyon–anyon etkileşiminin doğasını ve yük dağılımını görselleştirmek için kullanılmıştır. B3LYP/6-311++G(d,p) düzeyinde elde edilen MEP haritası Şekil 1'de gösterilmiştir. Negatif potansiyelin beklendiği üzere büyük ölçüde $B_3H_8^-$ anyonunun merkezinde ve B–H bağları çevresinde yoğunlaştığını; pozitif potansiyelin ise guanidinyum katyonu üzerinde yer aldığını göstermektedir. Bu yük ayrımı, klasik iyonik sıvı davranışıyla uyumlu olup, anyonun hidrojen bakımından zengin bölgelerinde elektron yoğunluğunun biriktiğini doğrulamaktadır.

Şekil 1. B3LYP/6-311++G(d,p) Yöntemi ile Hesaplanan İyonik Sıvının Moleküler Elektrostatik Potansiyeli (MEP)

ωB97X-D/6-311++G(d,p) ile hesaplanan MEP yüzeyi Şekil 2'de gösterilmiştir. Negatif potansiyelin $B_3H_8^-$ anyonunun daha iç bölgelerine doğru daha keskin ve lokalize bir dağılım sergilediğini ortaya koymaktadır. Bu sonuç, uzun menzilli değiş-tokuş–korelasyon terimlerini içeren fonksiyonelin, katyon–anyon arasındaki elektrostatik etkileşimleri ve dispersiyon kaynaklı katkıları daha güçlü biçimde yansıtmasından kaynaklanmaktadır. Yük yoğunluğunun bu ölçüde lokalize olması, güçlü iyonik etkileşimler ve yönlenmiş hidrojen bağları ile birlikte değerlendirildiğinde, $GuaB_3H_8$'in yüksek termodinamik kararlılığını destekleyen önemli bir bulgu olarak ortaya çıkmaktadır.

Şekil 2. ωB97X-D/6-311++G(d,p) Yöntemi ile Hesaplanan İyonik Sıvının Moleküler Elektrostatik Potansiyeli (MEP)

MEP analizleri, frontier orbital bulguları ile birlikte ele alındığında, $B_3H_8^-$ anyonunun hidrojen bakımından zengin bölgelerinin potansiyel reaktivite merkezleri olduğunu, guanidinyum katyonunun ise hem yük dengeleme hem de olası proton/elektron transfer süreçlerinde etkin bir rol üstlenebileceğini göstermektedir.

SONUÇ

Bu çalışmada guanidinyum oktahidrotriborat ($GuaB_3H_8$) iyonik sıvısı, B3LYP/6-311++G(d,p) ve ωB97X-D/6-311++G(d,p) düzeylerinde incelenmiştir. Elde edilen C–N, N–H, B–H ve B–B bağ uzunlukları, literatürde $[B_3H_8]^-$ için bildirilen deneysel ve kuramsal değerlerle uyumludur. Özellikle B–H bağları için 1.21–1.26 Å ve B–B bağları için 1.75–1.82 Å aralığı, kullanılan teorik seviyenin yapısal açıdan güvenilir olduğunu göstermektedir.

$GuaB_3H_8$ iyonik çiftinin bağlanma enerjileri B3LYP için −172.5 kcal/mol, ωB97X-D için −177.1 kcal/mol olarak hesaplanmıştır. Bu değerler, katyon ve anyon arasındaki elektrostatik çekim ve hidrojen bağı etkileşimlerinin çok güçlü olduğunu göstermektedir. Sistem gaz fazında yüksek termodinamik kararlılık

sergilemektedir. Bu kararlılık, hidrojen depolama açısından geri dönüşümlü dehidrojenasyon/rehidrojenasyon süreçlerinin dış koşullarla (sıcaklık, basınç, katalizör vb.) kontrol edilmesini gerektirebileceğine işaret etmektedir.

Frontier moleküler orbital analizi, HOMO'nun $B_3H_8^-$ anyonu üzerinde, LUMO'nun ise kısmen guanidinyum katyonu üzerinde lokalize olduğunu göstermiştir. HOMO–LUMO enerji aralıkları B3LYP için 4.9151 eV, ωB97X-D için 8.4296 eV bulunmuştur. Bu aralıklar, $GuaB_3H_8$'in benzer boran esaslı iyonik sıvılarla karşılaştırıldığında elektronikte kararlı, ancak uygun koşullarda reaksiyona girebilen bir sistem olduğunu düşündürmektedir. Özellikle ωB97X-D ile elde edilen daha geniş aralık, sistemin kinetik açıdan daha az reaktif bir rejimde yer aldığını göstermektedir.

Moleküler elektrostatik potansiyel (MEP) yüzeyleri, negatif potansiyelin $B_3H_8^-$ anyonu ve terminal B–H bağları üzerinde yoğunlaştığını ortaya koymuştur. Pozitif potansiyel ise guanidinyum katyonunun N–H bölgelerinde toplanmaktadır. Bu dağılım, $B_3H_8^-$ biriminin hidrojen transferi ve B–H aktivasyonu için nükleofilik/indirgeyici merkezler olabileceğini göstermektedir. Guanidinyum katyonu ise proton transferi, hidrojen bağı etkileşimleri ve olası koordinasyon için elektrofilik bir ortam sunmaktadır.

Genel olarak geometri, bağlanma enerjisi, HOMO–LUMO aralığı ve MEP sonuçları birlikte değerlendirildiğinde, $GuaB_3H_8$ iyonik sıvısının hem kararlı bir iyonik sıvı hem de hidrojen depolama ve transferi için umut verici bir aday olduğu görülmektedir. Bu çalışma, boran temelli iyonik sıvıların tasarımında kullanılabilecek temel yapısal ve elektronik verileri sağlamaktadır. Ayrıca gelecekte yapılacak deneysel hidrojen depolama çalışmaları ve reaksiyon yolları, bariyerler ve ortam etkilerini içeren ileri kuramsal incelemeler için bir başlangıç noktası sunmaktadır.

TEŞEKKÜR

Bu çalışmada yer alan nümerik hesaplamaların bir kısmı TÜBİTAK ULAKBİM, Yüksek Başarım ve Grid Hesaplama Merkezi'nin (TRUBA kaynakları) desteğiyle tamamlanmıştır.

Abstract

Crocus sativus contains several bioactive metabolites with known antioxidant, anti-inflammatory, and metabolic regulatory activities. Early-stage drug discovery increasingly relies on rapid *in silico* prediction tools to as drug-likeness and molecular interaction tendencies before conducting comprehensive experimental validation. This study offers a methodological evaluation of major *C. sativus* compounds crocetin, safranal, and picrocrocin using drug-likeness predictors and molecular docking workflows. Drug-likeness features were assessed with SwissADME, MolSoft, pkCSM, and ProTox-II, while exploratory docking was performed against biologically relevant target proteins. Results revealed compound-specific differences in physicochemical properties and interaction tendencies. The present study demonstrates the usefulness of bioinformatics tools for initial screening of phytochemicals and provides a framework for future drug discovery research.

Keywords: *Crocus sativus*, drug-likeness, molecular docking

INTRODUCTION

Crocus sativus L. (saffron) is a medicinally significant plant valued for its unique apocarotenoid composition, particularly crocin, crocetin, safranal, and picrocrocin. These metabolites are responsible for the characteristic color, aroma, and bioactivity of saffron, and have been widely investigated for their diverse pharmacological properties. Numerous studies indicate that C. sativus constituents exert potent antioxidant, anti-inflammatory, neuroprotective, and metabolic regulatory effects, positioning them as promising candidates for the development of novel therapeutic agents (Drif, 2015; Saadat et al., 2024). Crocin and crocetin, in particular, have been associated with mitochondrial protection, modulation of pro-inflammatory cytokines, and improvements in glucose and lipid homeostasis (Rameshrad et al. 2018, 2010; Asbaghi et al., 2021). Meanwhile, safranal and picrocrocin exhibit notable cytoprotective, anti-inflammatory, and neuroactive actions (Frusciante et al., 2024; Bathaie & Mousavi, 2010). Growing interest in natural products as drug candidates stems from their structural diversity, chemical novelty, and multi-target interaction potential. Nevertheless, many phytochemicals face significant limitations during drug development due to insufficient characterization of their physicochemical attributes, oral bioavailability, and toxicity parameters at early stages (Newman & Cragg, 2020). To overcome these challenges, computational prediction tools have become essential components of modern drug discovery pipelines. In silico approaches—including molecular docking, ADMET modeling, and drug-likeness screening—provide rapid, cost-effective insights into pharmacokinetic behavior, target interaction potential, and structural suitability before in vitro or in vivo validation (Lionta et al., 2014; Besli et al., 2025). Although the biological effects of C. sativus have been well documented, its major metabolites have not been comprehensively assessed within an integrated computational framework that combines drug-likeness filtering with multi-target docking. This represents a notable gap, particularly given the central roles of inflammatory and metabolic pathways in disorders such as obesity, diabetes, neurodegeneration, and chronic inflammation—conditions in which saffron constituents have shown beneficial effects (Asbaghi et al., 2021; Hosseini et al., 2018). Computational evaluation of these metabolites against relevant protein targets may offer new insights into their therapeutic potential and support rational prioritization of molecules for subsequent laboratory studies. Therefore, this study aims to present a bioinformatics-based framework for assessing the drug-likeness characteristics and preliminary docking tendencies of crocin, crocetin, safranal, and picrocrocin.

By emphasizing workflow design and qualitative trends, the study contributes to early-stage screening of saffron-derived phytochemicals and highlights the value of computational strategies in natural product research.

MATERIALS AND METHODS

Compound Selection and Structure Preparation

Four major bioactive constituents of *Crocus sativus* L.— **crocetin, safranal, and picrocrocin**—were selected based on their pharmacological relevance. Chemical identifiers (CID, SMILES) and available 3D conformers for each compound were obtained from the PubChem database (Kim et al., 2021). Molecular structures were converted to PDBQT format and subjected to energy minimization using **OpenBabel** (O'Boyle et al., 2011).

Drug-Likeness and ADMET Profiling

To evaluate early-phase pharmacokinetic suitability, drug-likeness and ADMET properties were assessed using multiple complementary web-based platforms:

SwissADME for physicochemical parameters, Lipinski/Ghose/Veber/Egan filters, bioavailability score, and gastrointestinal absorption prediction (Daina et al., 2017).

MolSoft for global drug-likeness scoring (MolSoft LLC, 2024).

pkCSM for ADMET modeling covering absorption, distribution, metabolism, and excretion (Pires et al., 2015).

ProTox-II for toxicity class prediction and putative toxicological endpoints (Banerjee et al., 2018).

Target Protein Selection and Preparation

Protein targets associated with inflammation, metabolic regulation, or oxidative stress were selected from the Protein Data Bank (PDB). Protein structures were prepared using AutoDockTools by removing crystallographic water molecules, adding polar hydrogens, and assigning **Kollman charges** (Morris et al., 2009).

Molecular Docking Procedure

Molecular docking simulations were performed using **AutoDock Vina** (Trott & Olson, 2010). Grid boxes were centered on the binding pockets based on either co-crystallized ligands or annotated active site residues. Ligand flexibility was handled using the Lamarckian genetic algorithm parameters adapted for Vina. Docking exhaustiveness was optimized to ensure reproducibility across runs.The three-dimensional binding poses and ligand–protein interactions were visualized and analyzed using **Discovery Studio Visualizer** (BIOVIA, 2021) and **UCSF Chimera** (Pettersen et al., 2004).

RESULTS and DISCUSSION

The physicochemical and pharmacokinetic assessments performed in this study revealed distinct profiles for the major *Crocus sativus* metabolites. Crocin and crocetin exhibited markedly high polarity and multiple violations of classical drug-likeness criteria, consistent with their glycosylated and hydrophilic structures. Their limited membrane permeability and restricted oral bioavailability observed *in silico* are in agreement with earlier pharmacokinetic studies, which describe poor intestinal absorption and extensive metabolic conversion in vivo (Umigai et al., 2012; Hosseini et al., 2018). Safranal, in contrast, showed a favorable combination of molecular weight, lipophilicity (logP), and structural flexibility, aligning closely with traditional parameters for orally active drug candidates and supporting previous reports describing its efficient absorption and systemic distribution (*Saadat et al., 2024*). Picrocrocin demonstrated intermediate characteristics—moderate polarity and constrained permeability—suggesting a more selective but still biologically relevant interaction potential.

ADMET prediction tools consistently indicated that safranal possesses the most drug-like profile, particularly with respect to absorption, metabolic stability, and predicted bioavailability. Crocin and crocetin again reflected the well-documented limitations of highly hydrophilic natural pigments, while all four compounds exhibited acceptable predicted toxicity profiles. A degree of variability was observed for crocetin depending on the toxicity model applied, which mirrors previous literature noting compound-dependent differences across computational frameworks (Asbaghi *et al., 2021*).

Docking analyses revealed trends that further supported these physicochemical profiles. Safranal and crocetin demonstrated stronger interaction tendencies toward selected inflammatory and metabolic protein targets, which aligns with experimental findings describing their anti-inflammatory and metabolic regulatory actions *(Rameshrad et al. 2018*; Frusciante et al., 2024). Crocin, due to its large steric bulk and pronounced polarity, displayed reduced compatibility with compact binding pockets, resulting in lower docking adaptability — a pattern also noted in previous computational studies of glycosylated carotenoids. Picrocrocin showed moderate yet target-specific binding tendencies, suggesting that although it is less studied pharmacologically, it may contribute to the overall multi-target activity profile of saffron extracts.

Overall, qualitative trends from the present study reinforce the established biological activities of *C. sativus* constituents, particularly their anti-inflammatory and metabolic regulatory effects. At the methodological level, these findings illustrate how integrating physicochemical filtering, drug-likeness evaluation, ADMET modeling, and preliminary docking can substantially enhance early-phase natural product–based drug discovery. Similar integrated computational workflows have been shown to streamline candidate prioritization and reduce the cost and time associated with experimental screening (Lionta et al., 2014; *Besli et al., 2025*).

Certain limitations should be acknowledged. The docking simulations employed here relied primarily on rigid receptor conformations and qualitative interpretation without full quantitative binding affinity reporting. Moreover, metabolite transformation of crocin and crocetin—known to occur rapidly in vivo—was not explicitly modeled. Full binding energy values, residue-level interaction maps, and detailed structure–activity analyses will be provided in a forthcoming high-impact journal manuscript.

Taken together, the combined results suggest that safranal holds the strongest potential as an orally bioavailable lead compound, while crocin, crocetin, and picrocrocin display selective yet meaningful interaction patterns that merit deeper structural and functional characterization in future experimental and computational studies.

ORAL PRESENTATION

Berberinin östrojen reseptörü (ER/PR) pozitif meme kanseri hücrelerinde trombosit mikropartikülleri aracılı proliferasyon ve migrasyon üzerindeki etkileri

Mujgan Cubuk, Merve Gurboga, Ozlem Bingol Ozakpinar, Derya Ozsavci
Marmara Üniversitesi, Eczacılık Fakültesi, Biyokimya Anabilim Dalı, İstanbul, Türkiye

*Sorumlu yazar e-mail: mujganbdg@gmail.com

Özet

Meme kanseri kadınlarda en sık görülen malignitedir ve kansere bağlı ölümlerin ikinci önde gelen nedenidir. Venöz tromboembolizm kanserin ilerlemesi ve kemoterapiye dirençte yaygın olarak rol oynamakta ve kanserli hastalarda mortalite sebepleri arasında ön sırada yer almaktadır. Meme kanserinde ve özellikle kanserin ileri evrelerinde, dolaşımdaki trombosit türevli mikropartikül (PMP) lerde artış olduğu; bu nedenle PMP'lerin erken tanıda, prognostik veya terapötik biyobelirteç olarak kullanılabileceği öne sürülmüştür. İlaç direncinin yaygınlığının artması, kemoterapideki non-spesifiklik ve toksisite sorunları, daha az toksik ve daha etkili terapötik ajanlarının geliştirilmesini gerekli kılmaktadır. Berberinin antioksidan, antiinflamatuvar, antidiyabetik ve antikanserojenik roller sergilediği; *in vitro* ve *in vivo* olarak güçlü bir trombosit agregasyon inhibitörü olduğu da bildirilmiştir. Bu özellikleri ile berberinin, meme kanserinde umut verici ve potansiyel bir kemoterapötik destek ajanı olarak kullanılabileceği belirtilmiştir. Bu çalışmadaki amacımız; PMP'lerin hormon bağımlı meme kanseri hücrelerinin (MCF-7) proliferasyonu ve migrasyonunda oluşturabileceği olası değişimleri belirlemek; doğal bir alkoloid olan berberinin, PMP aracılığıyla oluşan bu değişimlerdeki etkilerini inlemektir. 4 sağlıklı, erkek gönüllüden alınan tam kan örneklerinden seri santrifügasyon yöntemi yoluyla PMP'ler izole edilerek, örnekler -80 C de dondurulmuştur. Daha sonra örneklerde, Bradford yöntemi ile protein tayini yapılmıştır. PMP'ler ve berberinin, sağlıklı fare embriyonik fibroblast hücre hattı (NIH/3T3) ve MCF-7 meme kanseri hücreleri üzerindeki antiproliferatif/sitotoksik etkisinin belirlemek amacıyla ilk olarak MTT yöntemi, daha uzun zaman dilimlerindeki etkinliğinin ortaya çıkarılması amacıyla, "Gerçek Zamanlı Hücre Ölçer" cihazı ve migrasyon üzerindeki etkisinin belirlenmesi amacıyla, yara açma deneyi (scratch assay) gerçekleştirilmiştir. MTT bulguları, berberinin doza bağımlı olarak antiproliferatif ve sitotoksik etkinlik gösterdiğini; migrasyon deney sonuçları da berberinin benzer şekilde hücre göçünü inhibe edici etkisi olduğunu; PMP'nin ise hücre göçünü desteklediğini göstermektedir. Bu bulgular, PMP'lerin meme kanseri metastazında etkili olabileceğini, bu nedenle prognostik veya terapötik biyobelirteç olarak kullanılabileceğini desteklemektedir. Ayrıca, berberin meme kanserinde PMP tarafından indüklenen proliferasyon ve hücre göçünü inhibe edici etkileriyle yeni bir tedavi seçeneği olabilir.

Anahtar kelimeler: Mikropartikül, trombosit, meme kanseri, in vitro, berberin

The effects of berberine on platelet-derived microparticle–mediated proliferation and migration in estrogen receptor (ER/PR)-positive breast cancer cells

Abstract

Breast cancer is the most common malignancy in women and the second leading cause of cancer-related mortality. Venous thromboembolism contributes to cancer progression and chemotherapy resistance and ranks among the primary causes of mortality in cancer patients. In breast cancer, especially in advanced stages, increased levels of circulating platelet-derived microparticles (PMPs) have been reported, suggesting their value as early diagnostic, prognostic, or therapeutic biomarkers. The rising prevalence of drug resistance, together with the non-specificity and toxicity associated with chemotherapy, underscores the need for safer and more effective therapeutic agents. Berberine has been reported to exhibit antioxidant, anti-inflammatory, antidiabetic, and anticancer properties and functions as a potent inhibitor of platelet aggregation in vitro and in vivo. These characteristics indicate that berberine may serve as a promising chemotherapeutic adjuvant in breast cancer. This study aims to determine the alterations induced by PMPs in the proliferation and migration of hormone-dependent breast cancer cells (MCF-7) and to investigate the effects of berberine, an alkaloid, on these PMP-mediated changes. PMPs were isolated from whole blood obtained from four healthy male volunteers through serial centrifugation and stored at –80 °C. Protein quantification was performed using the

Bradford method. The antiproliferative and cytotoxic effects of PMPs and berberine on the healthy embryonic fibroblast line (NIH/3T3) and MCF-7 breast cancer cells were evaluated using the MTT assay; long-term effects were assessed with a Real-Time Cell Analyzer system, and migration was examined using a scratch assay. The MTT findings demonstrate that berberine exhibits dose-dependent antiproliferative and cytotoxic activity; the migration assay results similarly show that berberine exerts an inhibitory effect on cell migration, whereas PMPs promote migration. These findings suggest that PMPs may contribute to breast cancer metastasis and could serve as prognostic or therapeutic biomarkers. Berberine may also represent a therapeutic option by suppressing PMP-induced proliferation and migration.

Keywords: Microparticle, platelet, breast cancer, in vitro, berberine

GİRİŞ

Meme kanseri kadınlarda en sık görülen malignitedir ve kansere bağlı ölümlerin ikinci önde gelen nedenidir. Venöz tromboembolizm (VTE) ise, kanser ilerlemesinde ve antikanser tedavisine dirençte yaygın olarak rol oynamaktadır. VTE, hastalarda kanserin kendisinden sonra ikinci önde gelen ölüm nedenidir ve kanserli hastalarda VTE riski 7 kat daha fazladır (Chaari ve ark., 2014; Spuy ve Augustine, 2016). Kanser hücreleri, trombosit aktivasyonunu ve agregasyonunu uyarır, dolaşımdaki kanser hücreleriyle etkileşime giren trombositler, bağışıklık sistemine karşı koruyucu bir kalkan oluşturur (Vismara ve ark., 2021). Meme kanserinde dolaşımdaki trombosit kaynaklı mikropartiküllerin (PMP) plazma seviyelerinin yükseldiği; özellikle ileri evrelerdeki kanserin, dolaşımdaki PMP'lerde artışla ilişkili olduğu; inflamasyon, tromboz ve trombosit bağımlı metastaza aracılık edebildiği (Vismara ve ark., 2021); trombosit membranlarında bulunan P-selektin gibi fonksiyonel reseptörleri eksprese edebildiği ve farklı hücre tiplerine aktarabildiği (Baj-Krzyworzeka ve ark., 2002); böylece dolaşımdaki tümör hücrelerine yapışkan özellikler kazandırdığı (Cambien and Wagner D, 2004); dolayısıyla PMP'lerin erken tanıda, prognostik veya terapötik biyobelirteç olarak kullanılabileceği öne sürülmüştür. İlaç direncinin yaygınlığının artması, kanser kemoterapisindeki doku seçiciliği ve toksisite sorunları ile birleştiğinde, daha az toksik ve daha etkili terapötik ajanlarının geliştirilmesi yönünde gereklilikler ortaya çıkarmıştır.

Berberin antibakteriyel, hipolipidemik (Xing ve ark., 2021); antiplatelet (Wang ve ark., 2017; Wang ve ark., 2021); anti-diyabetik (El-Wahab ve ark., 2013; Wang ve ark., 2018); antioksidan, anti-inflamatuar, (Wang ve ark., 2020); antikanser (Almatroodi ve ark., 2022; Pierpaoli ve ark., 2021; Pan ve ark., 2017) özellikleri ile bilinen, bitkilerden elde edilen bir alkoloiddir. Yapılan çalışmalar, berberinin diğer antiplatelet ilaçlara göre avantajlı olabileceğini, kombinasyon kullanımına uygun olduğunu, umut verici bir antiplatelet ve anti-kanser ajan olabileceğini düşündürmektedir.

AMAÇ

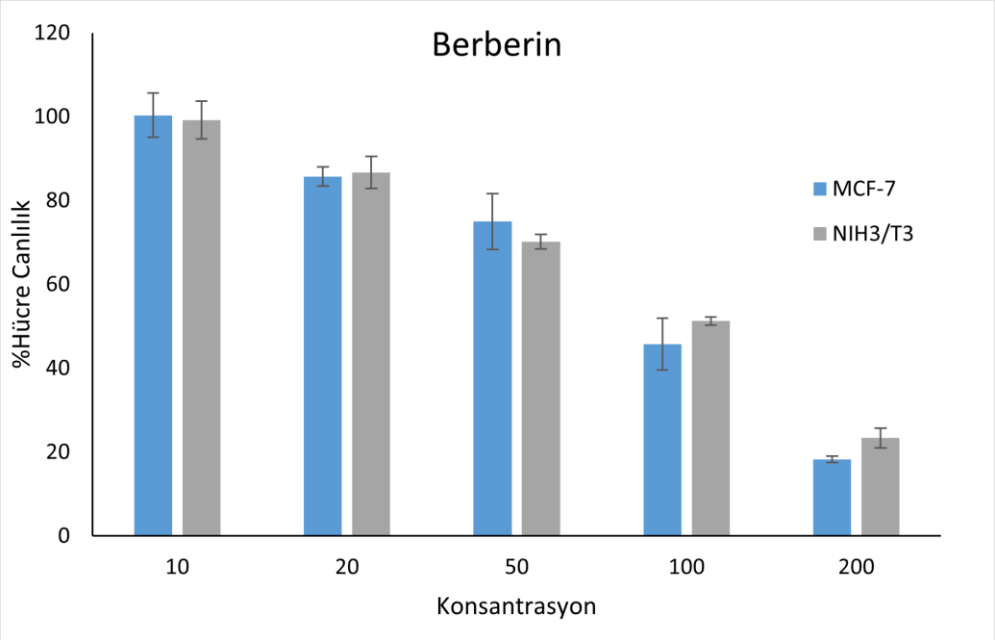
Bu çalışmanın amacı; PMP'lerin, hormon bağımlı meme kanserinde hücre proliferasyonu ve migrasyonunda oluşturabileceği değişimleri belirlemek; doğal bir alkoloid olan berberinin, meme kanserinde PMP aracılığıyla oluşan bu değişimlerdeki etkilerini karşılaştırmaktır.

MATERYAL VE METOT

4 sağlıklı, erkek gönüllüden sitratli tüplere tam kan örnekleri alınarak, santrifügasyon yöntemi ile önce trombositler izole edildi, daha sonra trombin aktivasyonu ve çeşitli tamponlarla dilüsyon/santrifügasyon işlemleri sonrasında da PMP'ler elde edildi ve Bradford yöntemi kullanılarak protein tayini yapıldı. İzole edilen PMP örnekleri kullanılıncaya kadar -80C de bekletildi.

MTT yöntemiyle antiproliferatif etkinin belirlenmesi

PMP'ler ve berberinin antiproliferatifk etkilerinin belirlenmesi için hormon duyarlı meme kanseri hücre hattı olarak MCF-7 ve sağlıklı hücreler üzerindeki sitotoksik etkisinin belirlemek amacı ile fare embriyonik fibroblast hücre hattı NIH/3T3 ile çalışıldı. Hücreler, 48 saat boyunca 10, 20, 50, 100, 200 µM berberin ile inkübe edildi. Örneklerin antiproliferatif etkisinin belirlenmesi için MTT yöntemi ve daha uzun zaman dilimlerindeki etkinliğin ortaya çıkarılması amacıyla "Gerçek Zamanlı Hücre Ölçer" cihazı kullanıldı.



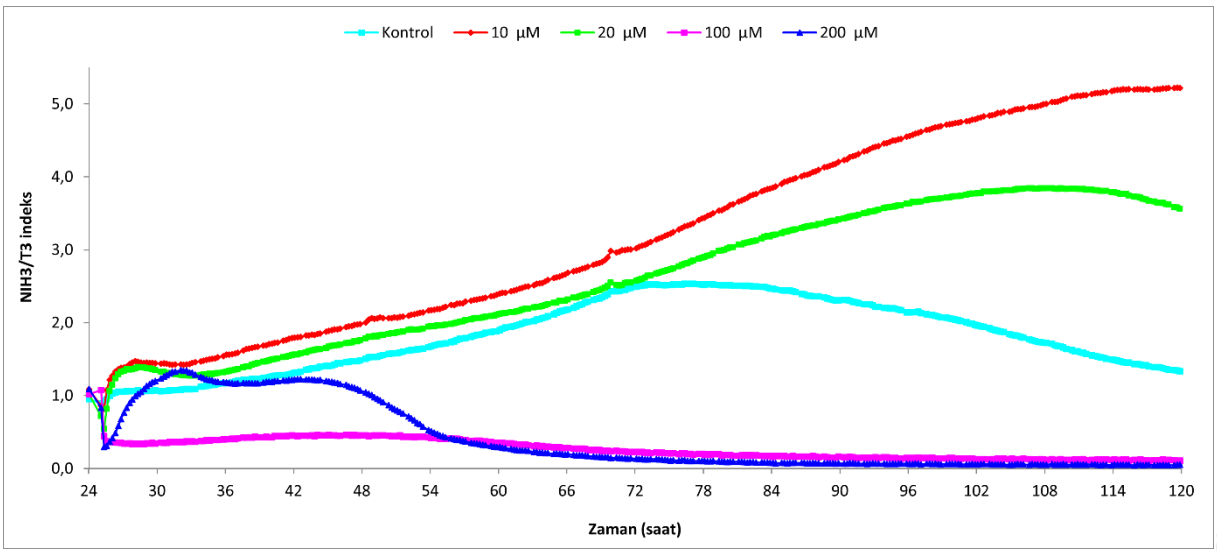
Yara iyileşme analizi (wound healing assay)

Berberin ve PMP'lerin MCF-7 hücre migrasyonu üzerine etkinin belirlenmesi amacıyla yara açma deneyi (scratch assay) gerçekleştirildi. MCF-7 hücreleri, her kuyucuğa eşit sayıda ekilerek uygun hücre yoğunluğuna ulaşmaları beklenmiştir. Hücre yoğunluğu sağlandıktan sonra, her kuyucuğa standart bir çizik açılmış ve bu an 0. saat olarak kaydedilmiştir. Deney grupları şu şekilde oluşturulmuştur: yalnızca 100 µM Berberin içeren grup, yalnızca PMP içeren grup (30 µg/ml), başlangıçta berberin uygulanıp, daha sonra PMP eklenecek olan kombinasyon grubu ve kontrol grubu. Deneyin 24. saatinde kuyucuklar yeniden görüntülenmiş ve berberin içeren gruplardan bazılarına ek olarak 24. saatte PMP uygulanarak kombinasyon oluşturulmuştur.

BULGULAR

Berberinin MCF-7 ve NIH/3T3 Hücre hatlarındaki Antiproliferatif ve Sitotoksik Etkisi

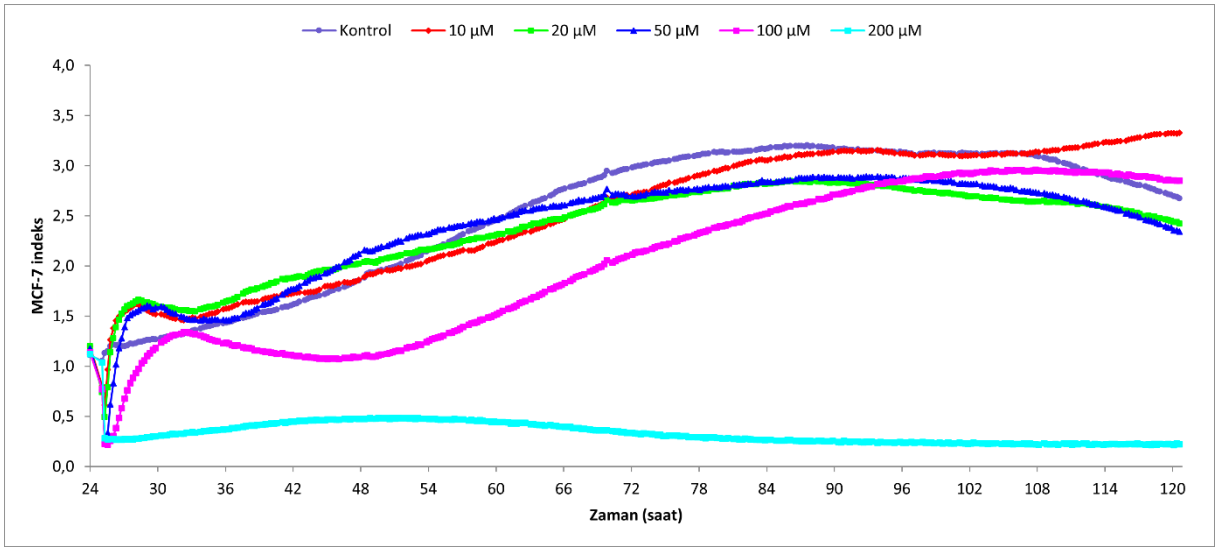
MTT sonuçlarına göre; berberin, uygulanan doz aralığında her iki hücre hattında da doza bağımlı bir inhibisyona sebep olmaktadır (Şekil 1). 50 µM konsantrasyondan itibaren MCF-7 hücre canlılığı NIH/3T3'e kıyasla daha düşüktür. MCF-7 hücreleri için berberinin IC_{50} (Yarı maksimum inhibitör konsantrasyon) değeri 106 µM, NIH/3T3 hücreleri için 119 µM olarak hesaplanmıştır.



Şekil 1. Berberin uygulanan NIH/3T3 ve MCF-7 hücrelerinin MTT sonuçları

Berberin Uygulanan MCF-7 ve NIH3T3 Hücrelerinin Gerçek Zamanlı Hücre Ölçer Bulguları

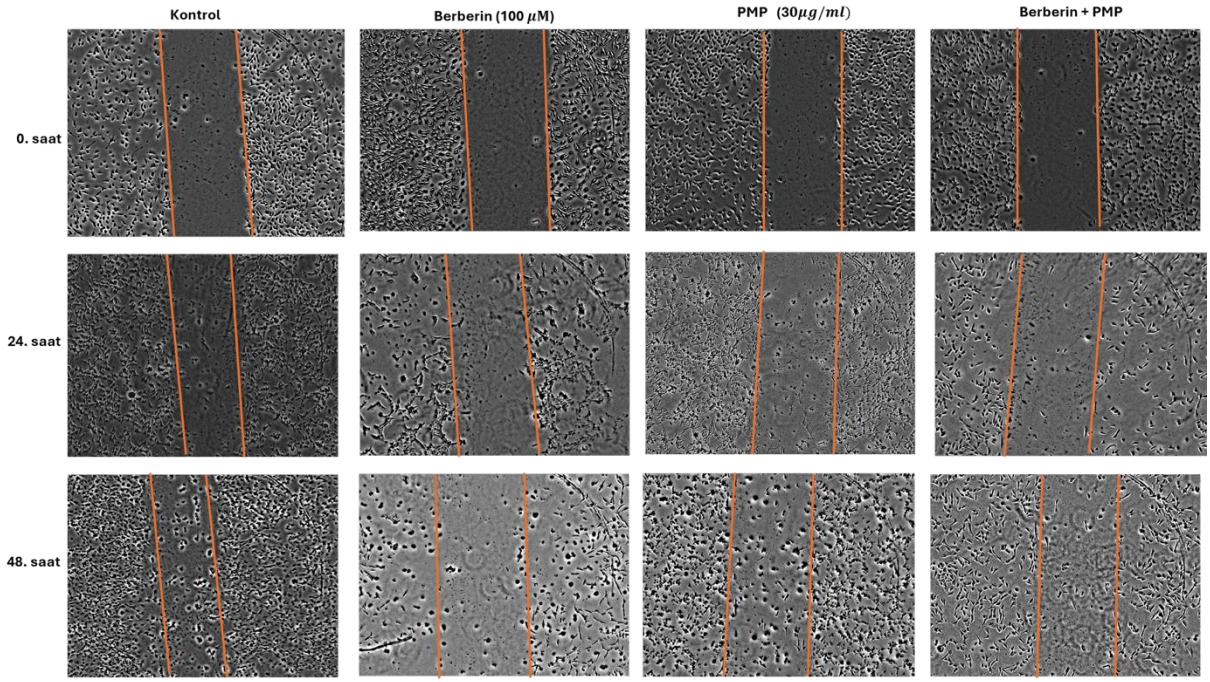
MTT deneylerinden sonra, hücre canlılığının izlenmesi için gerçek zamanlı hücre ölçer cihazı kullanıldı. NIH/3T3 ve MCF-7 hücrelerinin ekimi yapılan e-plakalarda 120 saat boyunca hücre indeksleri kaydedildi. Bu sayede zamana ve doza bağımlı olarak hücre proliferasyonunun nasıl bir değişime uğradığı gerçek zamanlı olarak belirlendi.



Berberin uygulanan NIH/3T3 hücrelerinde 10 ve 20 µM konsantrasyonlarda hücrelerin proliferasyona devam ettiği ve sitotoksik bir etki görülmediği belirlenmiştir. Uygulanan 100 µM konsantrasyonda ise hücre proliferayonu zaman içerisinde azalırken; 200 µM konsantrasyonda berberin uygulamasından sonraki yaklaşık 12. Saatten itibaren hücre sayısının bir anda azaldığı görülmektedir (Şekil 2- mavi).

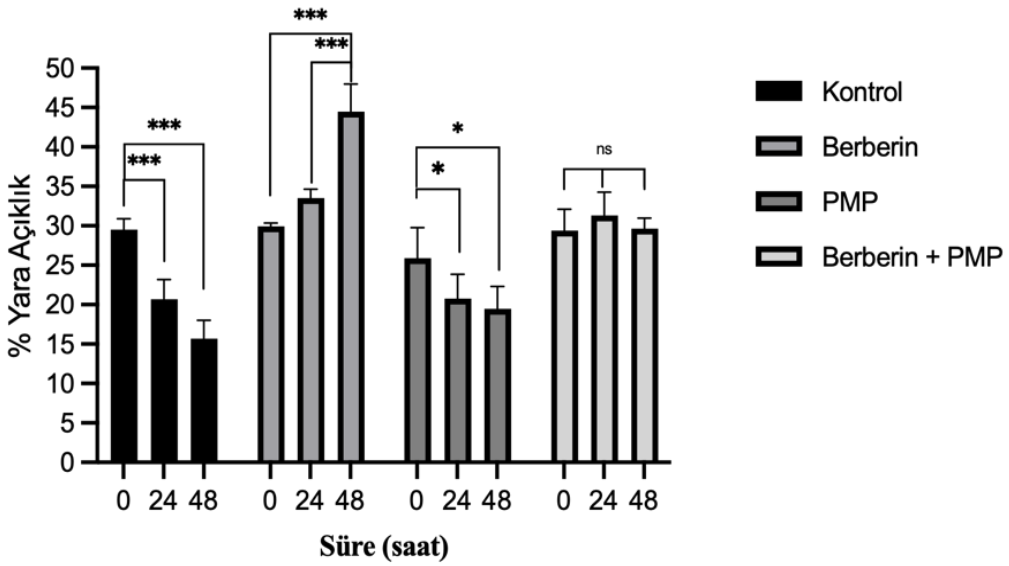
Şekil 2. Berberinin NIH/3T3 hücre hattındaki hücre canlılığına etkisi

Xcelligence sonuçlarına göre berberin, sağlıklı hücrelerde düşük dozlarda proliferatif etki; yüksek dozlarda proliferasyonu baskılayıcı ve sitotoksik etkiler göstermektedir.



Benzer etkinin MCF-7 hücrelerinde de görüldüğü belirlenmiştir. 10, 20 ve 50 µM berberin ile proliferasyon devam ederken; 100 µM berberin proliferasyonu bir süre baskılamaktadır. 200 µM konsantrasyon ise başlangıçtan itibaren hücre çoğalmasını durdurmaktadır (Şekil 3).

Şekil 3. Berberinin MCF-7 hücre hattındaki hücre canlılığına etkisi



Berberinin, PMP ve Kombinasyonunun MCF-7 hücre göçüne etkisi

Şekil 4 incelendiğinde, kontrol grubunda hücrelerin zamanla proliferasyona devam ettiği ve yara alanına doğru göç ederek çizik bölgesini kısmen kapattığı görülmektedir. Berberin uygulanan kuyucuklarda ise hücre sayısının zamanla azaldığı ve kontrol grubuna kıyasla çizik alanının belirgin şekilde açık kaldığı gözlenmiştir. Bu durum, berberinin hücre göçünü inhibe edici bir etkiye sahip olabileceğini göstermektedir.

Şekil 4. Berberin, PMP, berberin+PMP'nin, 48 saatteki MCF-7 yara kapanma etkisi.

Yalnızca PMP uygulanan grupta, kontrol grubuna benzer şekilde yara alanının önemli ölçüde kapandığı ve hücre proliferasyonunun sürdüğü dikkat çekmektedir (Şekil 5). Berberin ile önceden inkübe edilen hücrelere 24. saatte PMP eklenmesiyle oluşturulan kombinasyon grubunda, 48. saat sonunda berberinin inhibe edici etkisinin azaldığı ve PMP'nin ise hücre göçünü desteklediği düşünülmektedir.

Şekil 5. Berberin, PMP ve Berberin+PMP'nin MCF-7 hücre hattındaki yara açıklığına etkisinin zamana bağlı olarak 48 saatteki değişimi (*p<0,05, **p<0,01, ***p<0,001)

TARTIŞMA

Bu çalışmada elde edilen bulgular, Berberinin 100 ve 200 µM dozlarda daha sitotoksik olduğunu, terapötik potansiyelinin yanı sıra, sağlıklı hücreler üzerinde toksisite riskinin de olabileceğini; bu nedenle dozun kritik bir faktör olduğunu göstermektedir. Yani berberin, meme kanser hücrelerine karşı seçici bir antikanser profil sergilemiş; bu sitotoksik etkiler yara kapanma deneyinde de görülmüştür. Berberin uygulanan kuyucuklarda

hücre sayısının zamanla azaldığı ve kontrol grubuna kıyasla çizik alanının belirgin şekilde açık kaldığı gözlenmiştir. Bu durum, berberinin hücre göçünü inhibe edici bir etkiye sahip olabileceğini göstermektedir. PMP uygulanan grupta ise, yara alanının önemli ölçüde kapandığı ve hücre proliferasyonunun sürdüğü görülmüş yani PMP kanser hücrelerinin migrasyonunu arttırırken; berberin PMP'nin neden olduğu migrasyonu azaltmış ve yaranın kapanmasını antimigratif ve antiproliferatif etkilerle engellemiştir. Berberin ile önceden inkübe edilen hücrelere 24. saatte PMP eklenmesiyle oluşturulan kombinasyon grubunda, 48. saat sonunda berberinin inhibe edici etkisinin azaldığı ve PMP'nin ise hücre göçünü desteklediği görülmektedir.

Yapılan çalışmalarda, antikanser (Pierpaoli ve ark., 2021; Xiong ve ark., 2022; Du ve ark., 2022) ve apoptotik (Pan ve ark., 2022; Huang ve ark.,2023;; Fu ve ark., 2024; Zhu ve ark., 2020) özellikleri iyi bilinen berberinin, meme kanserinin önlenmesi ve tedavisi için umut verici bir ajan olabileceği (Xiong ve ark., 2022); altta yatan etki mekanizmaları arasında kanser hücresin çoğalmasını ve invazyonunu dolayısıyla metastazını engellemek, göçünü baskılamak, hücre döngüsünün ilerlemesini durdurmak olarak belirtilmiştir (Du ve ark., 2022). Bazı kanser hücre hatları için berberinin 100 µM'den daha yüksek konsantrasyonlarda etki ettiği; bununla birlikte, berberinin sitotoksik etkisinin 10 ila 100 µM arasında değiştiği için orta düzeyde olduğu (Rauf ve ark., 2021) gösterilmiştir. Bizim çalışmamız da bu çalışmalarla uyumludur.

Sıçanlarla yapılan bir *in vivo* çalışma, karaciğer ve böbrek toksisitesi de olmayan 13-Cys-BBR'nin inflamasyon, venöz tromboz, arteriyel tromboz, serum TNF-α ve serum P-selektinin mükemmel inhibitörü olduğunu kanıtlamaktadır (Li ve ark., 2020). Yapılan bir *in vitro* çalışmada ise, berberin kaynaklı CD31+/CD42− mikropartikül azalması, sağlıklı bireylerde endotel fonksiyonunun artışına katkıda bulunmuştur (Wang ve ark., 2009). Berberinin trombositler ve tromboz üzerine yapılmış çalışmaları olsa da, PMP üzerindeki etkisiyle ilgili çalışmalar yetersizdir. Bizim çalışmamızda, PMP kanser hücrelerinin migrasyonunu arttırırken; berberin PMP'nin neden olduğu migrasyonu azaltmış ve yaranın kapanmasını antimigratif ve antiproliferatif etkilerle engellemiştir. Berberinin, antikanser özelliklerinin yanında anti-inflamatuvar ve anti-trombotik etkileri de bulunduğu için, PMP'nin neden olduğu kanser hücrelerinin migrasyonundaki etkileri geri çevirmesi, literatürdeki diğer çalışmalarla uyumludur.

Trombositler kanser ilerlemesinde yaygın olarak rol oynamaktadır ve PMP'ler ise trombosit-kanser etkileşiminin potansiyel aracıları olarak giderek daha fazla ilgi görmektedir (Vismara ve ark., 2021). Genel olarak, PMP'lerin anjiyogenezi, hücre proliferasyonunu (Oliveira ve ark., 2024; Lazar ve ark., 2021) ve bağışıklık hücrelerinden kaçışını düzenleyerek kanser metastazını güçlendirdiği kabul edilmektedir (Jaiswal ve ark., 2017). Meme kanseri de dahil olmak üzere çeşitli kanser türlerinde dolaşımdaki PMP'lerin yaygın olarak plazma seviyelerinin yükseldiği, inflamasyon ve tromboza aracılık edebildiği (Anghel ve ark., 2020; Geddings ve ark., 2013; Bucciol ve ark., 2023; Sheikh ve ark., 2020); dolaşımdaki PMP'lerin yüksek miktarlarının genellikle ileri metastatik evre ile ilişkili olduğu belirtilmiştir (Zara ve ark., 2017). Ancak, az sayıda araştırma, PMP'lerin kanser baskılayıcı rolleri olabileceğini de öne sürmüştür. Ayrıca, PMP'lerin kanser hücre biyolojisi üzerindeki etkilerine ilişkin bilgilerimiz sınırlıdır ve sıklıkla çelişkili sonuçlar bildirilmiştir (Vismara ve ark., 2021). Kanser hastalarında dolaşan PMP'lerin artışını destekleyen mekanizmalar yeterince anlaşılmamıştır. Diğer taraftan, PMP'lerin spesifik etkilerinin trombositlerden veya diğer hücrelerden türetilen MP'lerin etkilerinden ayrılmasındaki zorluklar nedeniyle yeterince anlaşılmamıştır (Lazar ve ark., 2021).

SONUÇ

PMP'lerin meme kanserindeki rolünü değerlendiren bu sınırlı çalışmalara rağmen, prokoagülan PMP'lerin tanımlanması, tedavileri özelleştirmek ve kişiselleştirmek için meme kanser teşhisinde potansiyel bir prognostik biyobelirteç ve gelecekte umut vadeden bir tromboz biyobelirteci olabilir Berberin ise, hem meme kanserinin hem de trombotik hastalıkların veya kardiyovasküler/serebrovasküler olayların önlenmesinde ve tedavisinde kullanılabilecek umut verici bir ajan olabilir.

TEŞEKKÜR

Bu çalışmaya sağlıklı gönüllülerden kan alımı için laboratuvar imkânları ile verdikleri katkılar için Doç. Dr. Hasan Alaçam'a ve Ahenk Laboratuvarı ekibine teşekkür ederiz.

Abstract

Aluminum-activated malate transporters (ALMTs) constitute a prominent anion channel family involved in essential physiological processes in plants, including nutrient uptake, metal tolerance, stomatal regulation, cellular pH homeostasis, signal transduction, and cell expansion. We performed comprehensive bioinformatics analyses, including chromosomal distribution, gene structure, motif composition, conserved domain architecture, phylogeny, synteny with *Arabidopsis thaliana*, protein physicochemical characterization, Ka/Ks-based evolutionary assessment, 3D protein structure prediction, and protein–protein interaction analysis. 21 HaALMT genes were found in the sunflower genome in this paper. The motif structures of the proteins in the same phylogenetic tree were similar, and the α-helical form was dominant in most proteins. Synteny analysis identified conserved collinear regions for *HaALMT7* and *HaALMT18* with *A. thaliana*, supporting their shared evolutionary origin. Additionally, protein–protein interaction predictions highlighted TAFII31 and SAGA-associated factor 11 as major interaction partners, implying regulatory functions that extend beyond malate transport. The findings provide novel insights into the evolutionary history, structural diversity, and potential functional roles of *HaALMT* genes in sunflower adaptation to environmental stress.

Keywords: Aluminum-activated malate transporters, *Helianthus annuus*, genome-wide idenificaion

INTRODUCTION

Aluminum-activated malate transporters (ALMTs) comprise a versatile group of anion channels that participate in multiple physiological processes, including mineral homeostasis, detoxification of metal ions, stomatal regulation, and maintaining intracellular pH stability (Roelfsema and Hedrich, 2005). Rather than functioning as a single-pathway system, ALMTs act as dynamic regulators that help plants integrate environmental cues with metabolic responses. The solubilization of Al^{3+} creates a hostile environment that rapidly interferes with root structure and cellular integrity in acidic soils. Plants counter these effects through various defense mechanisms, and ALMT-mediated malate release is a central component of this response (Le Poder et al., 2022).

The defining structural feature of the ALMT family is the conserved PF11744 domain, supported by several transmembrane helices that allow efficient transport of anionic molecules across cellular membranes (Medeiros et al., 2018 ; Dabravolski and Isayenkov, 2023). Although these proteins are best known for their role in organic acid efflux under aluminum exposure, accumulating evidence suggests that they function more broadly in processes such as fruit acidity modulation, guard-cell turgor adjustment, and signaling pathways involving γ-aminobutyric acid (GABA) (Sharma et al., 2016). Variations in subcellular localization, such as the tonoplast-associated *AtALMT6* and *AtALMT9*, further illustrate the functional diversity of this gene family.

Sunflower (*Helianthus annuus* L.) is the world's fifth most significant oilseed crop and is widely cultivated under diverse environmental conditions. Exposure to abiotic stresses triggers complex signaling and transcriptional reprogramming in sunflowers, mediated by transcription factors (TFs) and downstream regulatory networks. Identifying stress-related gene families such as *ALMTs* is essential for understanding sunflower adaptation mechanisms and for improving stress resilience through molecular breeding and functional genomics (Li et al., 2020).

In this study, we systematically identified *ALMT* gene family members in the sunflower genome and performed comprehensive structural, evolutionary, and functional analyses. Our results provide insights into the organization, expansion, and potential roles of *HaALMT* genes in abiotic stress responses, contributing valuable information for future functional studies and stress-resilient sunflower breeding strategies.

MATERIALS AND METHODS

Identification and Characterization of ALMT Genes in the Sunflower Genome

ALMT genes in *H. annuus* were identified by querying the PF11744 domain against the *H. annuus* reference genome (version r1.2) (Goodstein et al., 2012) available in the Phytozome database. Protein sequences of *Arabidopsis thaliana* ALMT family members were retrieved from the NCBI database (https://www.ncbi.nlm.nih.gov/) and used as reference queries. Homologous sequences in sunflower were identified using BLASTP searches in TBtools-II with an e-value threshold of $<1e^{-5}$ (Chen et al., 2023). The presence of the ALMT domain in each candidate sequence was validated through the Pfam database (http://pfam.xfam.org/) (Mistry et al., 2021). Physicochemical properties, including molecular weight, theoretical isoelectric point (pI), instability index, and GRAVY scores, were calculated using the ExPASy ProtParam tool (https://web.expasy.org/protparam/) (Gasteiger et al., 2005).

Chromosomal Localization and Synteny Analysis

Genomic coordinates of *HaALMT* genes were obtained from Phytozome and displayed with TBtools-II. To assess the evolutionary conservation of the ALMT family, synteny between the *H. annuus* and *A. thaliana* genomes was analyzed. Corresponding FASTA and GFF3 datasets were retrieved from Phytozome, and syntenic blocks were identified through the One-Step MCScanX module in TBtools-II. Collinearity patterns were subsequently illustrated with the Dual Synteny Plot function (Wang et al., 2012).

Gene Structure and Conserved Motif Analysis

The intron–exon organization of *HaALMT* genes was characterized with the Gene Structure View module in TBtools-II. Conserved motifs in *HaALMT* protein sequences were detected with the MEME Suite under default settings, and the resulting motif architectures were rendered using TBtools-II.

Phylogenetic Analysis and Gene Duplication Assessment

Multiple sequence alignments of ALMT proteins from sunflower, *A. thaliana*, *Zea mays*, and *Oryza sativa* were generated with the MUSCLE algorithm. Phylogenetic trees were inferred using the Maximum Likelihood approach with 1000 bootstrap replicates in MEGA v12.0 (Kumar et al., 2018) and visualized through the iTOL platform (Letunic and Bork, 2007). Evolutionary divergence was assessed by estimating nonsynonymous (Ka) and synonymous (Ks) substitution rates, as well as the Ka/Ks ratio, using TBtools-II (Wang and Zhang, 2010).

Three-Dimensional (3D) Protein Structure Prediction and Protein–Protein Interaction (PPI) Analysis

Structural predictions of *HaALMT* proteins were generated using the SWISS-MODEL server, and the resulting 3D models were assessed based on sequence identity and confidence metrics. Protein–protein interaction networks were inferred through the STRING database to identify potential interacting partners and functional associations (Mering et al., 2003 ; Szklarczyk et al., 2023).

RESULTS AND DISCUSSION

In this study, 21 *HaALMT* genes were identified in the sunflower genome through BLAST searches using *A. thaliana* ALMT sequences. Genes were named with the prefix “Ha” and ordered according to their chromosomal positions. *HaALMT* proteins range from 273 to 1863 amino acids, with predicted pI values between 4.97 and 5.37, indicating an overall acidic nature. Among the 21 proteins, nine (42.85%) are classified as unstable, and twelve (57.14%) are classified as stable. Their molecular weights range from 22.6 to 153.9 kDa. Subcellular localization predictions indicate that most *HaALMT* members (85.71%) are associated with the plasma membrane, while the remainder localize to the nucleus/chloroplast, cytoplasm/chloroplast, or extracellular matrix/chloroplast compartments.

To examine the evolutionary relationships of *HaALMT* proteins, ALMT sequences from *A. thaliana* (14 members), *Z. mays* (9 members), and *O. sativa* (9 members) were analyzed. Earlier studies reported 22 *ALMT* genes in *A. thaliana* (Guo et al., 2008), 25 in *Z. mays* (Lin et al., 2011), and 10 in *O. sativa* (Guo et al., 2008). The number of Arabidopsis genes identified in this study did not fully match those published in these datasets.

The 21 identified *HaALMT* genes were mapped across the 17 sunflower chromosomes (Figure 1). Previous studies in *Solanum tuberosum* and Orchidaceae reported ALMT distributions on seven chromosomes (Zhang et al., 2023; Peng et al., 2024). Phylogenetic analysis revealed that *HaALMT* proteins cluster into four major groups (Figure 2a), with Group II containing the largest number of members (nine genes).

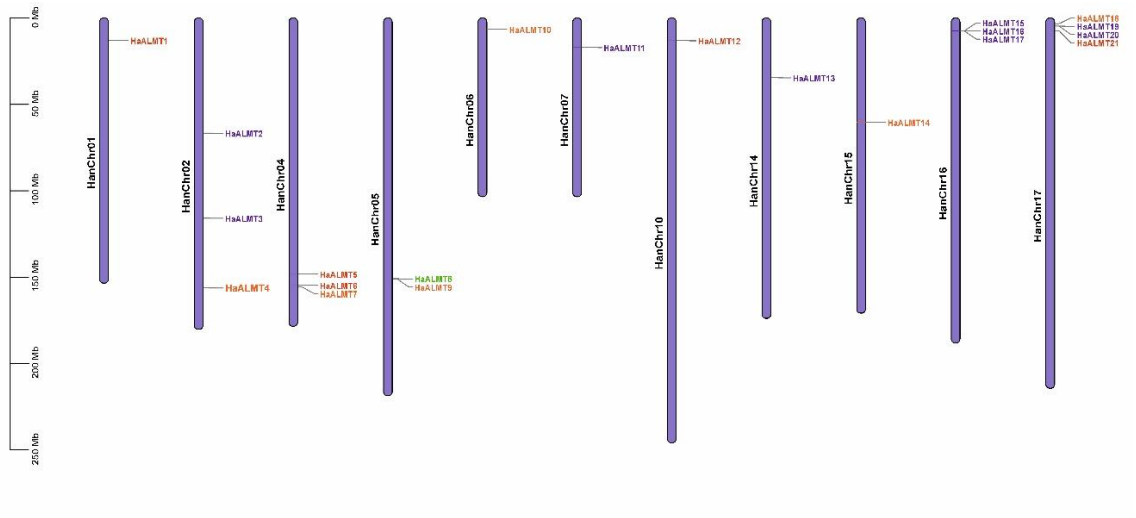

Figure 1. The distribution of all *HaALMT* genes on sunflower chromosomes

In contrast, *HaALMT8* in Group III showed no close evolutionary relationship with other species. Ten conserved motifs were detected in sunflower (Figure 2b); motifs 1, 2, 3, 4, 5, 6, 7, and 9 were shared among *HaALMT14, 10, 18, 5, 6, 21,* and *3*, while *HaALMT8* contained only motif 9. In contrast, 15 conserved motifs were reported in *Medicago sativa* and *Hevea brasiliensis* (Jin et al., 2024). All *HaALMT* proteins carried the FUSC superfamily domain—consistent across all phylogenetic groups—and the ALMT superfamily domain, except *HaALMT15*, which contained only the ALMT domain. FUSC, previously associated with membrane transport, cell division, and intracellular trafficking (Utsumi et al., 1991), supports the multifunctional nature of ALMT proteins beyond aluminum tolerance. Gene structure analysis showed that most *HaALMT* genes comprise five to six exons, whereas *HaALMT9* contains three, and *HaALMT15* and *HaALMT21* contain two exons (Figure 2b), differing from the six-exon structure reported for *M. sativa* (Jin et al., 2024).

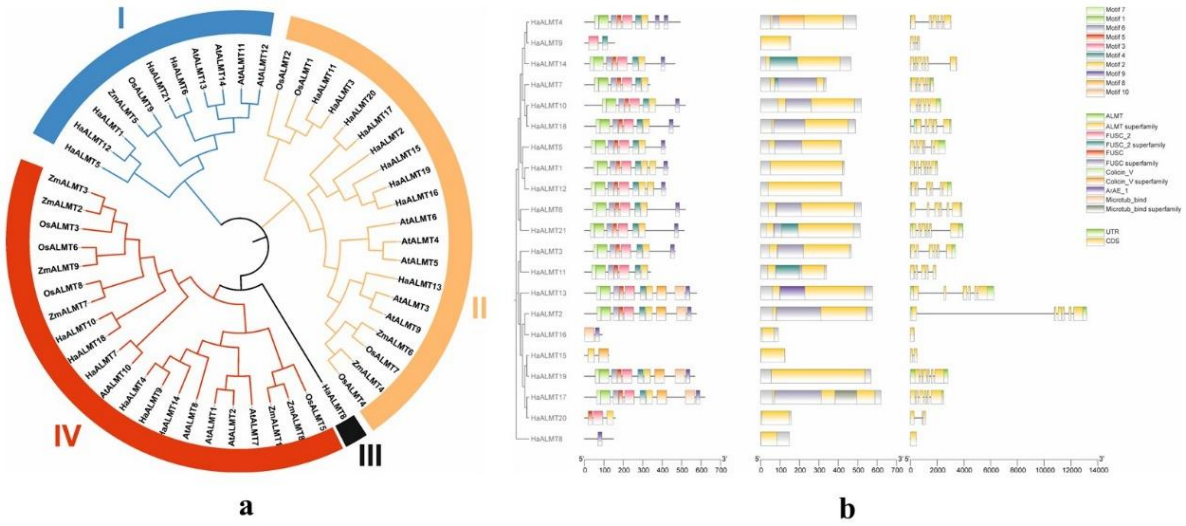

Figure 2. Phylogenetic analysis of *HaALMT* genes. The ML tree was constructed with 1000 bootstraps (a), the exon-intron organization, motif, and domain analysis of *HaALMT* genes (b)

HaALMT genes exhibited extensive duplication, comprising 128 segmental and eight tandem events, with duplication blocks present on all chromosomes except chromosomes 3, 8, 9, 11, 12, and 13. Selection pressure analysis revealed mean Ka, Ks, and Ka/Ks values of 0.7789, 1.846, and 0.461, respectively. Twelve *HaALMT* proteins were successfully modeled with a confidence level of greater than 90% and all displayed α–helix–rich folding patterns, consistent with earlier structural predictions (Zhang et al., 2023). Protein–protein interaction

analysis identified strong interactions—50 in total—between *HaALMT* proteins and two major partners: Putative transcription initiation factor TAFII31 (A0A251SGY5) and SAGA-associated factor 11 (A0A251TAY2). TAFII31 is known to contribute to the assembly and stability of the TFIID and TFTC complexes through its histone-fold domain (Leurent, 2002), while the ZnF domain of SAGA-associated factor 11 mediates zinc binding (Samara et al., 2010). Given that ALMT channels regulate malate efflux and intracellular pH—factors influencing zinc transport—these interactions likely reflect coordinated roles in stress signaling and cellular organization. Comparative synteny analysis with *A. thaliana* revealed clear collinearity for *HaALMT7* and *HaALMT18* with their Arabidopsis homologous regions (Figure 3).

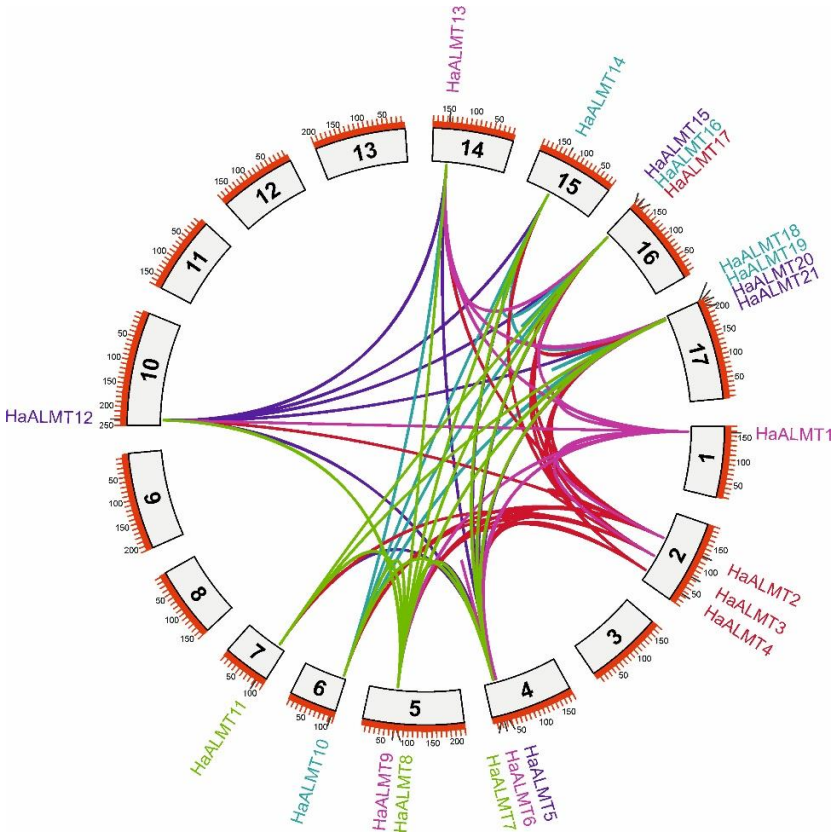

Figure 3. Localization and synteny of *ALMT* genes in *Helianthus annuus*

CONCLUSION

This paper provides a comprehensive characterization of 21 *HaALMT* genes in the sunflower genome, revealing their distribution across 17 chromosomes and highlighting 128 segmental and eight tandem duplication events that have contributed to the expansion of the family. Phylogenetic analysis resolved the genes into four major clades, with Group II being the most enriched. At the same time, motif and domain assessments demonstrated strong structural conservation across members, except for unique features observed in *HaALMT8* and *HaALMT15*. Synteny comparisons revealed clear collinear relationships between HaALMT7 and HaALMT18, as well as *A. thaliana*, indicating shared evolutionary origins. Structural modeling confirmed α-helix–rich architectures in 12 proteins, and protein–protein interaction analyses pinpointed TAFII31 and SAGA-associated factor 11 as key functional partners, suggesting broader regulatory roles beyond malate transport. Overall, these insights deepen our understanding of *ALMT* gene evolution and function in sunflowers, offering a valuable foundation for future studies aimed at enhancing aluminum tolerance and stress resilience.

Özet

Bitki Doku Kültürü, karmaşık genetik ve çevresel etkileşimler nedeniyle geleneksel optimizasyon yöntemlerinin Tek Faktörlü Denemeler, Cevap Yüzeyi Metodolojisi gibi konularda yetersiz kalmaktadır. Bu çalışma, küresel literatürde Yapay Zeka (YZ), Makine Öğrenimi (ML) ve Robotik uygulamalarının Bitki Doku kültüründeki dönüşümsel potansiyelini incelemektedir. Makine Öğrenimi teknikleri (Yapay Sinir Ağları - Genetik Algoritma, Genel Regresyon Sinir Ağı - Baskın Olmayan Sıralamalı Genetik Algoritma II), kültür ortamı bileşenlerinin ve eksplant sterilizasyon prosedürlerinin eşzamanlı, çok amaçlı optimizasyonunda Cevap Yüzeyi Metodolojisi'ne göre üstünlük sağlamış, kalitatif girdileri ele alarak tür bazında hassas formülasyona olanak tanımıştır. Derin Öğrenme algoritmaları (Evrişimli Sinir Ağları), somatik embriyogenez aşama tanıma, mikrobiyal kontaminasyon ve vitrifikasyon gibi fizyolojik streslerin otomatik tespitinde, nesnellik ve hız sunar. Robotik sistemler (RoBoCut, Janus Transplanter) ile otomasyon, mikroçoğaltmada toplam üretim maliyetinin %50-70'ini oluşturan işgücü maliyetlerini azaltırken, Yapay Zeka rehberli 3D görüntü tanıma kalitenin tutarlılığını artırmaktadır. Ayrıca yapay zeka, CRISPR/Cas9 Genom Düzenleme Sistemi uygulamalarında (Random Forest modeli üstünlüğü) hedef dışı sekans tahminini iyileştirerek genetik hassasiyeti yükseltmektedir. Ana zorluklar, veri heterojenliği, yüksek ilk yatırım maliyetleri ve Derin Öğrenmenin yorumlanabilirlik eksikliğidir. Çözümler, Açıklanabilir Yapay Zeka entegrasyonu ve disiplinlerarası işgücü eğitimini gerektirmektedir. Sonuç olarak, Yapay Zeka'nın Bitki Doku Kültürüne entegrasyonu, süreçlerin hassasiyetini, sürdürülebilirliğini ve maliyet etkinliğini artırarak biyoteknolojinin endüstriyel ölçekte ilerlemesini sağlamaktadır.

Anahtar Kelimeler: Yapay Zeka, Bitki Doku Kültürü, Makine Öğrenimi, Robotik, Optimizasyon, CRISPR

Intelligent Bioprocesses, Artificial Intelligence, and Machine Learning in Plant Tissue Culture

Abstract

Plant Tissue Culture faces persistent yield limitations because conventional optimization methods such as One Factor at a Time and Response Surface Methodology cannot fully capture the complex interactions among genetic, physiological, and environmental factors. This review summarizes global research on how Artificial Intelligence, Machine Learning, Deep Learning, and robotics are reshaping Plant Tissue Culture by improving efficiency, precision, and scalability.

Machine Learning models including Artificial Neural Network Genetic Algorithm combinations and Generalized Regression Neural Network systems combined with advanced multi objective optimization strategies have demonstrated superior performance compared to Response Surface Methodology. These models can simultaneously optimize medium components including macro and micronutrients and improve explant sterilization procedures. Their ability to process qualitative variables supports species specific and highly accurate formulation of culture conditions.

Deep Learning, particularly Convolutional Neural Networks, provides rapid and objective detection of contamination, vitrification, somatic embryogenesis stages, and other physiological stresses. Robotic platforms such as RoBoCut and Janus Transplanter reduce labor costs, which traditionally account for most micropropagation expenses. Artificial Intelligence supported three dimensional image analysis further enhances quality consistency and production throughput.

Artificial Intelligence also advances genetic precision. In applications of the CRISPR Cas9 genome editing system, Machine Learning models such as Random Forest improve the prediction of off target effects. Despite these advantages, several challenges remain including heterogeneous data sets, high initial investment requirements, and limited interpretability of Deep Learning models. The adoption of Explainable Artificial Intelligence systems such as SHAP and the development of interdisciplinary expertise are essential to overcoming these limitations.
Overall, the integration of Artificial Intelligence into Plant Tissue Culture supports more sustainable, precise, and economically viable biotechnological production systems and strengthens the path toward industrial scale advancement.

Keywords: Artificial Intelligence, Plant Tissue Culture, Machine Learning, Robotics, Optimization, CRISPR

1.GİRİŞ

Bitki Doku Kültürü, hızlı çoğaltım (mikroçoğaltma), temiz bitki programlarının oluşturulması ve genetik mühendisliği süreçlerinin kolaylaştırılması için modern tarım ve biyoteknolojide hayati bir platform görevi görmektedir (Hesami ve Jones, 2025). Küresel gıda güvenliğinin sağlanması, dünya nüfusunun sürekli artışı ve iklim değişikliğinin tarımsal sistemler üzerindeki baskısının artması gibi zorluklar karşısında, Bitki Doku Kültürü merkezi bir konuma sahiptir (Hesami ve Jones, 2025). Bu bağlamda, yüksek verimli, hastalıklara ve değişen çevresel koşullara dayanıklı yeni çeşitlerin hızla geliştirilmesi zorunludur. Bu zorunluluk, bitki ıslahı süreçlerinde yüksek verimli omik teknolojilerinin kullanımını kaçınılmaz kılmakta ve büyük veri analizi ihtiyacını doğurmaktadır (Ali ve ark., 2023).

Geleneksel Optimizasyon Yaklaşımlarının Sınırlamaları
In vitro sistemlerin başarısı, genetik, fizyolojik ve çevresel faktörler arasındaki karmaşık, doğrusal olmayan etkileşimlere ve biyolojik varyansa derinden bağlıdır (Hesami ve Jones, 2025). Geleneksel deneysel ve istatistiksel optimizasyon yaklaşımları, özellikle Tek Faktörlü Denemeler (OFAT) ve Cevap Yüzeyi Metodolojisi (RSM), bu karmaşık dinamiklerle başa çıkmada yapısal sınırlamalar taşımaktadır (Hesami ve Jones, 2025). Geleneksel yöntemler, kültür ortamı bileşenlerinin optimal kombinasyonunu belirlemeye çalışırken yavaş, zahmetli ve verimsizdir.

Özellikle RSM, etkileşimli etkileri ele alabilse de, regresyon modellerine dayanması nedeniyle kalitatif girdileri (örneğin, farklı karbonhidrat türleri, jelleştirici ajanlar veya eksplant tipleri) karşılaştırmada ciddi kısıtlamalara sahiptir (Hesami ve Jones, 2025). Bu durum, tür bazında hassas formülasyona ulaşılmasını engelleyerek Bitki Doku Kültürü uygulamalarının tam potansiyeline ulaşmasını engellemiştir. Ayrıca, biyolojik deneylerde yaygın olan eksik veri setleri veya kontaminasyon gibi deterministik olmayan sorunlar, geleneksel istatistiksel analiz yöntemlerini zorlamaktadır (Hesami ve Jones, 2025). Bu metodolojik zorluk, yeni nesil veri odaklı yaklaşımların benimsenmesini bilimsel bir zorunluluk haline getirmiştir.

1.2. Yapay Zeka ve Robotik Entegrasyonunun Dönüşümsel Potansiyeli

Yapay Zeka (AI), Makine Öğrenimi (ML) ve Derin Öğrenme (DL) gibi hesaplamalı teknolojilerin entegrasyonu, bitki biyoteknolojisi alanında devrim niteliğinde bir potansiyel sunmaktadır (Hesami ve Jones, 2025). Bu teknolojiler, geleneksel yöntemlerle yönetilmesi imkansız olan büyük hacimli ve karmaşık verileri analiz etme, tahmin etme ve optimize etme kapasitesine sahiptir (Hesami ve Jones, 2025).

Yapay Zeka-destekli yaklaşımların temel vaadi, *in vitro* kültür protokollerinin hassasiyetini, sürdürülebilirliğini ve maliyet etkinliğini artırmaktır. Tarihsel olarak büyük ölçüde ampirik ve "zanaat odaklı" bir süreç olan Bitki Doku Kültürü, Yapay Zeka'nin devreye girmesiyle birlikte, veri yapılarının protokol tasarımını yönlendirdiği standardize edilmiş, endüstriyel bir bilime doğru niteliksel bir geçiş yapmaktadır (Hesami ve Jones, 2025; Tohme ve ark., 2024). Bu paradigma değişimi, biyolojik materyaller ile hesaplama modelleri arasında köprü kurabilen, bitki biyolojisi, bilgisayar bilimleri ve robotik alanlarında uzmanlaşmış personele olan acil ihtiyacı da beraberinde getirmektedir (Tohme ve ark., 2024; Cabrera ve ark., 2023).

2. KURAMSAL TEMELLER VE LİTERATÜR

Bu literatür taraması, AI, ML, DL ve robotik sistemlerin Bitki Doku Kültürü süreçlerini optimize etmek, otomatikleştirmek ve genetik hassasiyeti artırmak amacıyla küresel düzeyde nasıl kullanıldığını incelemektedir. İncelenen metodolojiler, esas olarak biyolojik karmaşıklığı ele alabilen ve geleneksel istatistiksel modellerin sınırlamalarını aşan hibrit hesaplama çerçevelerine odaklanmıştır.

Temel Makine Öğrenimi ve Derin Öğrenme Mimarileri

Bitki Doku Kültürü protokollerinin optimizasyonunda kullanılan Yapay Zeka araçlarının yelpazesi geniştir ve Yapay Sinir Ağları (YSA/ANN), Destek Vektör Makineleri (SVM), Rastgele Orman (RF), Genel Regresyon Sinir Ağları (GRNN) ve DL modellerini (Örneğin Evrişimli Sinir Ağları - CNN'ler, Tekrarlayan Sinir Ağları - RNN'ler) içermektedir (Guo ve ark., 2024; Hessami ve ark., 2023). Bu algoritmalar, yüksek verimli omik teknolojilerinden elde edilen büyük miktardaki genetik ve fenotipik veriyi verimli bir şekilde analiz etmek için kritik öneme sahiptir (Ali ve ark., 2023).

ML teknikleri, RSM'nin aksine, yalnızca kantitatif girdileri değil, aynı zamanda karbonhidrat türleri veya jelleştirici ajanlar gibi kalitatif girdileri de optimize edebilme yeteneği sunar (Hesami ve Jones, 2025). Bu esneklik, karmaşık ve deterministik olmayan veri setlerinin ele alınmasını kolaylaştırır. Ayrıca, ML modelleri mutlak konsantrasyonlar yerine, iyonlar arasındaki fizyolojik etkileşimleri yansıtan oranları hesaplama özellikleri olarak dönüştürerek, tahmine dayalı performansı artırmanın yanı sıra biyolojik açıdan anlamlı bilgiler üretme kapasitesine de sahiptir (Hesami ve Jones, 2025). Bu yetenek, ML'yi sadece bir tahmin aracı olmaktan çıkarıp, fizyolojik denge teorilerini doğrulayan veya keşfeden bir keşif aracı haline getirmektedir.

2.2. Hibrit Çok Amaçlı Optimizasyon Metodolojileri

Bitki Doku Kültürü'nde eşzamanlı ve çelişkili protokol hedeflerinin (örneğin, sürgün sayısını maksimize ederken fizyolojik anormallikleri minimize etmek) optimizasyonunu sağlamak için en ileri yaklaşım, tahmin algoritmalarının evrimsel optimizasyon algoritmaları ile entegrasyonudur (de-Carvalho ve ark., 2021; Jafari ve ark., 2023).

2.2.1. Metot Entegrasyonu:

YSA-GA Entegrasyonu: Yapay Sinir Ağları (YSA/ANN), girdi (ortam bileşimi) ve çıktı (sürgün kalitesi/büyümesi) arasındaki karmaşık, doğrusal olmayan ilişkileri modeller. Genetik Algoritma (GA) ise, YSA modeli tarafından tahmin edilen sonuçları kullanarak, istenen tüm hedefleri maksimize eden optimal girdi kombinasyonunu belirler (de-Carvalho ve ark., 2021).

GRNN-NSGA-II Entegrasyonu: Genel Regresyon Sinir Ağı (GRNN), genellikle MLP veya RBF gibi diğer sinir ağı modellerine göre üstün tahmin doğruluğu sergilemektedir (Jafari ve ark., 2023). Baskın Olmayan Sıralamalı Genetik Algoritma II (NSGA-II) ise, GRNN'nin tahminlerini kullanarak, Pareto optimum çözümler kümesini belirler. Böylece kontaminasyon oranını minimize etme ve çimlenme yüzdesini maksimize etme gibi çelişkili hedefleri eşzamanlı olarak çözebilir (Jafari ve ark., 2023). Bu hibrit metodolojiler, geleneksel tek amaçlı istatistiksel yaklaşımların biyolojik sistemlerin karmaşıklığını tam olarak yansıtamadığını göstermektedir.

2.3. Endüstriyel Otomasyon ve Robotik Sistemler

Robotik sistemler, yüksek verimli ve tutarlı mikroçoğaltma operasyonları sağlamak için AI'ın analitik gücü ile birleştirilmiştir (Tohme ve ark., 2024). Bu sistemlerin temel görevi, işgücü maliyetlerini azaltmak ve kalite tutarlılığını artırmaktır.

2.3.1. Robotik Platformlar:

(I) RoBoCut Sistemi: AI rehberli 3D görüntü tanıma kullanarak hijyenik kesme ve ayırma işlemleri için bir lazeri yönlendirir. Bu sistem, bitkicik başarısızlık oranlarını ve genel üretim maliyetlerini düşürür (Tohme ve ark., 2024).

(II) Janus Transplanter: Olgun bitkiciklerin steril laboratuvar ortamından *ex vitro* (steril olmayan) koşullara otomatik olarak aktarılmasını (transplantasyon) gerçekleştirir (Tohme ve ark., 2024).

(III) Otomatik Görüntü İşleme: AI destekli makine görüşü, büyüme oranları ve morfolojik özellikler gibi kritik parametreleri invaziv olmayan bir şekilde değerlendirir, ayrıca vitrifikasyon (hiperhidrisite) veya mikrobiyal kontaminasyon gibi fizyolojik streslerin erken belirtilerini objektif ve tutarlı bir şekilde tespit eder (Tohme ve ark., 2024; DL Contamination, 2023).

2.4. Hesaplamalı ve Teknolojik Uygulamaların Performans Metrikleri

İncelenen literatür, AI ve robotik sistemlerin Bitki Doku Kültürü süreçlerinde geleneksel metodolojilere göre belirgin bir üstünlük sağladığını ortaya koymaktadır.

Çok Amaçlı Optimizasyonda Kanıtlanmış Üstünlük
Hibrit Makine Öğrenimi (ML) ve Evrimsel Algoritma (EA) entegrasyonları, kültür ortamı bileşimi ve eksplant sterilizasyon protokolleri gibi temel Bitki Doku Kültürü süreçlerinin optimizasyonunda yüksek performans göstermiştir.

Ortam Formülasyonu: Kiwi berry (*Actinidia arguta*) üzerindeki çalışmalarda, YSA-GA entegrasyonu, standart ortamlara kıyasla hem sürgün büyümesini maksimize eden hem de bazal kallus (BC) ve hiperhidrisite (H) gibi fizyolojik anormallikleri önemli ölçüde azaltan optimize edilmiş bir mineral karışımı ("R ortamı") tahmin etmiştir (de-Carvalho ve ark., 2021).

Sterilizasyon Protokolleri: GRNN-NSGA-II metodolojisi, dezenfektan konsantrasyonu ve daldırma süresinin optimal seviyesini bulmak için kullanılmış ve kontaminasyon oranını minimize etme ile çimlenme yüzdesini maksimize etme gibi çelişkili hedefleri eşzamanlı olarak çözmede yüksek güvenilirlik kanıtlamıştır (Jafari ve ark., 2023). Bu bulgular, çok amaçlı biyolojik optimizasyonun etkin bir şekilde çözülebilmesi için hibrit algoritmaların gerekliliğini doğrulamaktadır.

Kallus İndüksiyonu: Petunya doku kültüründe, Çok Katmanlı Algılayıcı (MLP), Radyal Temelli Fonksiyon (RBF) ve Genel Regresyon Sinir Ağı (GRNN) algoritmaları kallus oluşumu indüksiyonunu tahmin etmek için karşılaştırılmış; GRNN'nin geleneksel istatistiksel yöntemlere kıyasla üstün tahmin doğruluğu sergilediği rapor edilmiştir (Jafari ve Daneshvar, 2023).

Yapay Zeka Destekli Görüntü Tanıma ve Kalite Kontrol
Derin Öğrenme teknikleri, kültürü invaziv olmayan bir şekilde izlemek ve kalite kontrolü sağlamak için kritik başarılar elde etmiştir (Guo ve ark., 2024; DL Contamination, 2023).

Gelişimsel Aşama Tanıma: Evrişimli Sinir Ağlarına (CNN'ler) dayalı çerçeveler, somatik embriyogenez (SE) aşamalarının (küresel, kalp, torpido ve kotiledon) otomatik olarak saptanması ve sınıflandırılması için transfer öğrenimi ve derin özellik çıkarma tekniklerini kullanmaktadır (Guo ve ark., 2024). Bu otomasyon, manuel seçimin öznelliğini ve yüksek işgücü yoğunluğunu ortadan kaldırarak SE aşamalarının tanımlanmasını standartlaştırmada kritik rol oynamaktadır (Guo ve ark., 2024).

Hastalık ve Stres Tespiti: CNN'ler, mikrobiyal kontaminasyonun otomatik tespiti konusunda yüksek doğruluk ve sağlamlık sergilemiştir (DL Contamination, 2023). Ayrıca, AI destekli makine görüşü, yüksek verimli sistemlerin ve kriyoprezervasyon canlılığının sınırlarını belirleyen vitrifikasyon (hiperhidrisite) gibi fizyolojik streslerin erken belirtilerini objektif ve tutarlı bir şekilde tespit eder (Popelka ve ark., 2023; Tohme ve ark., 2024). Bu erken tespit yeteneği, rejenerasyon yeteneğine sahip bitkicik yüzdesini doğrudan iyileştirmektedir.

Robotik Sistemlerin Operasyonel Verimlilik Etkisi
Robotik ve otomasyonun Bitki Doku Kültürüne entegrasyonu, laboratuvar operasyonlarını endüstriyel ölçeğe taşımıştır. Bu sistemlerin kullanılmasının temel ekonomik gerekçesi, mikroçoğaltımda toplam üretim maliyetinin **%50 ila %70'ini** oluşturabilen işgücü maliyetlerini önemli ölçüde azaltmaktır (Tohme ve ark., 2024).

RoBoCut ve Janus Transplanter: Yapay Zeka rehberli 3D görüntü tanıma kullanan RoBoCut sistemi, hijyenik kesim ve ayırma işlemlerinde bitkicik başarısızlık oranlarını ve genel üretim maliyetlerini düşürdüğü bildirilmiştir (Tohme ve ark., 2024). Janus Transplanter ise, *ex vitro* adaptasyon sürecinde olgun bitkicikleri otomatik olarak fide tepsilerine aktararak verimi artırmaktadır (Tohme ve ark., 2024). Robotik operasyonların hassasiyeti, manuel elleçlemeden kaynaklanabilecek mikrobiyal kontaminasyon riskini en aza indirerek kalite tutarlılığını sağlamlaştırmaktadır (Tohme ve ark., 2024).

Genom Düzenleme Hassasiyetinde İyileşme

Yapay Zeka, Bitki Doku Kültürü teknikleriyle sinerjik olarak çalışan CRISPR/Cas9 Genom Düzenleme Sistemi'nin genetik hassasiyetini artırmada önemli rol oynamaktadır (Chakraborty ve ark., 2022). Yapay Zeka'nin buradaki birincil uygulaması, hedef dışı (off-target) sekans konumlarını ve düzenleme sonuçlarını doğru bir şekilde tahmin etmektir (Chakraborty ve ark., 2022).

Model Karşılaştırması: CRISPR hedef dışı sekans tahminleri için bitki verileri üzerinde yapılan karşılaştırmalı analizler, **Random Forest (RF)** modelinin, geleneksel ML yöntemleri olan Destek Vektör Makineleri (SVM) ve Yapay Sinir Ağlarına (ANN) kıyasla bitki genom verilerinde daha iyi performans gösterdiğini ortaya koymuştur (Chakraborty ve ark., 2022). Bu bulgu, bitki genom yapısının benzersiz zorluklar sunduğunu ve memeli sistemlerinden elde edilen biyomedikal araçların basit adaptasyonu yerine, *bitki bilimlerine özgü* hesaplama modellerinin geliştirilmesi gerektiğini teyit etmektedir (Chakraborty ve ark., 2022).

Hesaplamalı Biyolojinin Sentezi ve Entegrasyon Zorlukları

Biyolojik Anlamlılığın Hesaplamalı Sentezi

Makine Öğrenimi modellerinin başarısı, yalnızca nicel tahminler yapma yeteneklerinden değil, aynı zamanda iyonlar arasındaki oranlar gibi fizyolojik etkileşimleri yansıtan yeni, türetilmiş özellikleri (özellik mühendisliği) öne çıkarma yeteneklerinden de kaynaklanmaktadır (Hesami ve Jones, 2025). Bu yaklaşım, AI'ın basitçe deneysel korelasyonların ötesine geçtiğini göstermektedir. ML, bitki performansını etkileyen altta yatan biyolojik mekanizmaları (örneğin, iyonik denge) doğrulayan veya keşfeden bir hipotez üreticisi olarak işlev görmektedir (Hesami ve Jones, 2025). Bu, Bitki Doku Kültüründe AI'ın benimsenmesinin, karmaşık biyolojik sistemlerin *doğasını modellemek* için bir zorunluluk olduğunu teyit etmektedir.

Ayrıca, Random Forest gibi özel algoritmaların CRISPR hedef dışı tahmininde üstünlük sağlaması (Chakraborty ve ark., 2022), bitki genomlarının karmaşık ve tekrar eden yapısının, genel amaçlı biyomedikal algoritmalar yerine, *fitosentrik* yani bitki merkezli hesaplama çözümlerinin geliştirilmesi gerektiğini açıkça ortaya koymaktadır (Chakraborty ve ark., 2022).

Şeffaflık ve Yorumlanabilirlik Engeli: Açıklanabilir Yapay Zeka (XAI)

Derin Öğrenme modellerinin yüksek tahmine dayalı doğruluk sunmasına rağmen, doğası gereği yorumlanabilir olmaması ("Kara Kutu" sorunu), bilimsel şeffaflık ve son kullanıcı (ıslahçılar, düzenleyiciler) güveni için önemli bir zorluk teşkil etmektedir (Wang ve ark., 2024). Biyolojik keşif, bir tahminin *neden* yapıldığını anlamayı gerektirir; bu, biyolojik bilgiyi ilerletmek için hayati öneme sahiptir.

Bu zorluğun üstesinden gelmek için Açıklanabilir Yapay Zeka (XAI) tekniklerinin entegrasyonu esastır (Wang ve ark., 2024). **SHAP (SHapley Additive exPlanations)** değer analizi gibi XAI teknikleri, tahminleri yönlendiren spesifik genetik lokusları veya çevresel değişkenleri tanımlayarak hem global hem de yerel yorumlanabilirlik sağlamaktadır (Wang ve ark., 2024). Yorumlanabilirlik, aynı zamanda düzenleyici uyumluluk için de kritik bir zorunluluktur; Yapay Zeka tarafından optimize edilen genom düzenleme çalışmalarının ticari ve politik kabulü için gerekli olan şeffaflığı (tahmini hangi faktörün yönlendirdiği) sağlamaktadır (Wang ve ark., 2024). Bu nedenle, XAI entegrasyonu, model tasarımının başlangıç aşamasından itibaren önceliklendirilmelidir.

Yapısal ve Sosyo-Ekonomik Zorluklar

Yapay Zeka sistemlerinin Bitki Doku Kültürü'ne entegrasyonu, veri altyapısı ve ekonomik engeller gibi önemli yapısal zorluklarla karşılaşmaktadır (Cabrera ve ark., 2023).

Veri Yönetimi ve Standardizasyon Zorlukları: Yapay Zeka modellerinin başarısı, yeterli, kaliteli ve standartlaştırılmış verilere erişime bağlıdır. Biyolojik ve tarımsal verilerin (genomik, fenomik) yüksek heterojenliği, farklı laboratuvarlar arasında tutarsız standardizasyonla birleşince, modellerin genelleştirilebilirliği için ciddi engeller oluşturmaktadır (Cabrera ve ark., 2023). Ayrıca, biyolojik materyaller ile Yapay Zeka uygulamaları için kullanılan dijital veriler arasında yeterli ve doğru "zemin doğrusu" bağlantısının kurulamaması, model geliştirme ve doğrulama için gerekli güvenilir verilerin elde edilmesini engellemektedir (Cabrera ve ark., 2023).

Stratejik Çözümler: Veri bütünlüğünü sağlamak ve genetik kaynakların güvenli, değişmez bir şekilde depolanmasını sağlamak amacıyla **Blockchain** teknolojisi gibi çözümlerin kullanılması teşvik edilmelidir (Elmushraf ve ark., 2023). Ayrıca, veri gizliliği endişelerini gidermek ve merkezi veri toplama ihtiyacı olmaksızın tescilli veri kümelerinde öğrenmeyi sağlamak için, **Federasyonlu Öğrenme (Federated Learning)** metodolojisi, gelecekteki araştırma yönelimleri arasında yer almalıdır (Guo ve ark., 2024). Robotik sistemlerin entegrasyonu, Yapay Zeka modellerinin kronik veri açığını kapatmak için gereken yüksek hacimli, standardize edilmiş veriyi sağlayan zorunlu bir altyapıyı oluşturmaktadır (Tohme ve ark., 2024).

Yüksek Başlangıç Maliyetleri ve İşgücü Dönüşümü: Sofistike robotik sistemlerin ve özel AI altyapısının uygulanmasının getirdiği yüksek ilk yatırım maliyetleri, özellikle küçük ölçekli operasyonlar için önemli bir giriş engeli oluşturmaktadır (Tohme ve ark., 2024; Cabrera ve ark., 2023). Otomasyon, manuel işgücünü azaltırken, robotik, hesaplama ve AI modelleme uzmanlığına sahip yeni bir uzman işgücü talebi yaratır (Tohme ve ark., 2024). Bu, personel becerilerini yeniden geliştirmek için önemli yatırımlar gerektirmekte ve kamu veya kişisel verilerden elde edilen faydaların eşit olmayan dağıtılmasıyla karakterize edilen "Dijital feodalizm" riskini beraberinde getirmektedir (Cabrera ve ark., 2023).

SONUÇ

Bitki Doku Kültüründe Yapay Zeka ve Makine Öğrenimi entegrasyonu, alanın temelden dönüşümünü sağlamış ve endüstriyel ölçekte ilerlemesi için kritik bir paradigmayı temsil etmektedir. Geleneksel Tek Faktörlü Denemeler (OFAT) ve Cevap Yüzeyi Metodolojisi (RSM) gibi yöntemlerin sınırlamalarının aksine, hibrit algoritmik modeller (YSA-GA ve GRNN-NSGA-II) kültür ortamı bileşenlerinin hassas formülasyonunda ve eksplant sterilizasyon protokollerinin çok amaçlı optimizasyonunda kanıtlanmış bir üstünlük sergilemiştir (de-Carvalho ve ark., 2021; Jafari ve ark., 2023).

Derin Öğrenme teknikleri, özellikle Evrişimli Sinir Ağları, somatik embriyogenez aşama tanıma ve mikrobiyal kontaminasyon tespiti gibi süreçlerde yüksek hız ve nesnellik sağlayarak kalite kontrol süreçlerini dönüştürmüştür (Guo ve ark., 2024; DL Contamination, 2023). Robotik sistemlerin (RoBoCut, Janus Transplanter) otomasyonu, işgücü maliyetlerini %50-70 oranında azaltarak operasyonel verimliliği artırmakta ve Yapay Zeka modellerinin eğitimi için gereken yüksek kaliteli, standardize edilmiş veriyi sağlamaktadır (Tohme ve ark., 2024). Genetik hassasiyet alanında ise, Random Forest gibi fitosentrik ML modellerinin CRISPR/Cas9 hedef dışı sekans tahminini iyileştirdiği görülmüş, bu da bitki sistemlerine özgü hesaplama çözümlerinin gerekliliğini pekiştirmiştir (Chakraborty ve ark., 2022).

Gelecek Araştırmaları ve Stratejik Öneriler

Yapay Zeka'nin Bitki Doku Kültürü'daki potansiyelinin tamamını gerçekleştirmek ve mevcut yapısal engellerin üstesinden gelmek için aşağıdaki stratejik adımların atılması zorunludur:

Açıklanabilir Yapay Zeka (XAI) Entegrasyonunun Zorunlu Kılınması: Biyolojik keşfi artırmak, altta yatan fizyolojik mekanizmaları anlamak ve Yapay Zeka güdümlü ürünlerin ticari/düzenleyici kabulünü sağlamak amacıyla, SHAP gibi XAI metodolojilerinin tahmine dayalı model geliştirmede öncelikli olarak entegre edilmesi gerekmektedir (Wang ve ark., 2024). XAI, bilimsel şeffaflığı güvence altına almanın temel aracıdır.

Küresel Veri Standardizasyonunun ve Güvenli Altyapıların Kurulması: Veri heterojenliği engellerinin üstesinden gelmek için küresel veri standardizasyon protokolleri acilen zorunlu kılınmalıdır (Cabrera ve ark., 2023). Ayrıca, Federasyonlu Öğrenme metodolojisinin uygulanması, merkezi veri paylaşımı gerekmeksizin model genelleştirilebilirliğini artıracaktır (Guo ve ark., 2024). Blockchain gibi teknolojiler, kritik genetik ve kültürel verilerin güvenliğini ve değişmezliğini sağlamalıdır (Elmushraf ve ark., 2023).

Disiplinlerarası İşgücü Gelişimine Stratejik Yatırım: Bitki Bilimi, Robotik ve Hesaplamalı Biyoloji kesişiminde uzmanlaşmış yeni bir profesyonel nesil yetiştirilmelidir (Tohme ve ark., 2024). Bu, hem laboratuvar otomasyonunu yönetmek hem de Yapay Zeka modellerini geliştirmek ve yorumlamak için kritik öneme sahiptir. Yüksek teknolojiye geçişin getirdiği "Dijital feodalizm" riskini azaltmak amacıyla, hesaplama ve modelleme platformlarına erişimin adil dağılımı sağlanmalıdır (Cabrera ve ark., 2023).

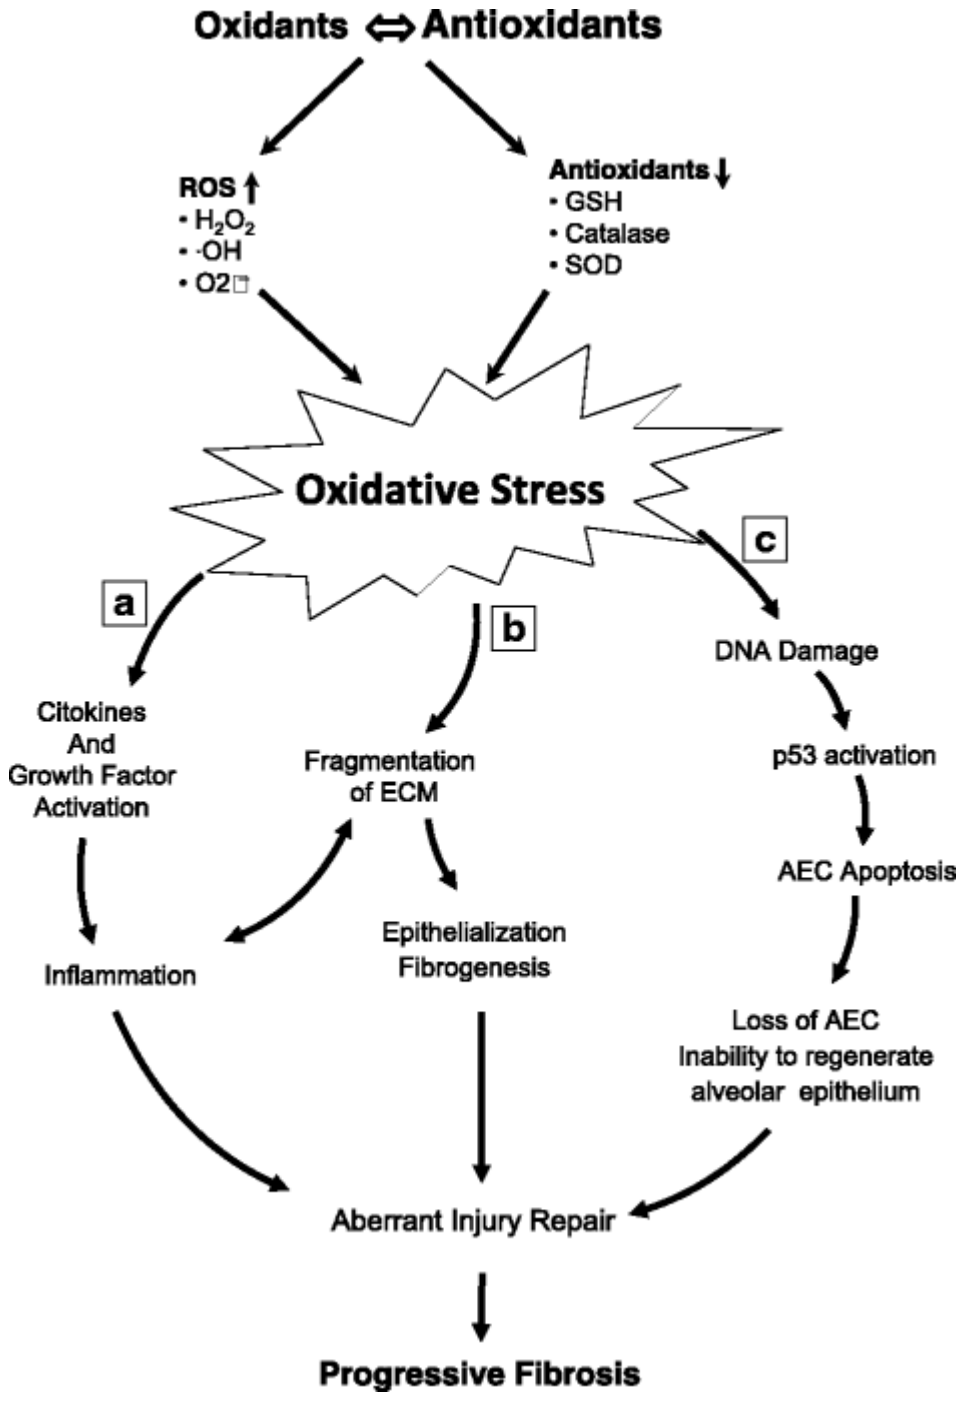
Özet

Pulmoner fibroz, ilerleyici interstisyel akciğer hastalıklarının önemli bir grubunu oluşturur ve oksidatif stres, hastalığın patogenezinde merkezi bir role sahiptir. Antioksidan genler, reaktif oksijen türlerini (ROS) nötralize eden enzimleri kodlayarak hücresel redoks dengesinin korunmasını sağlar. Bu derleme çalışmasında, pulmoner fibrozis bağlamında antioksidan genlerin düzenlenmesi ve ilgili genlerin fonksiyonları literatür eşliğinde sunulmaktadır.

Anahtar Kelimeler: Pulmoner fibroz, Nrf2, antioksidan genler, oksidatif stres, HO-1, NQO1, oxidative stress response, antioxidant enzymes, idiopathic pulmonary fibrosis

Regulation of antioxidant genes in pulmonary fibrosis- a review

Abstract



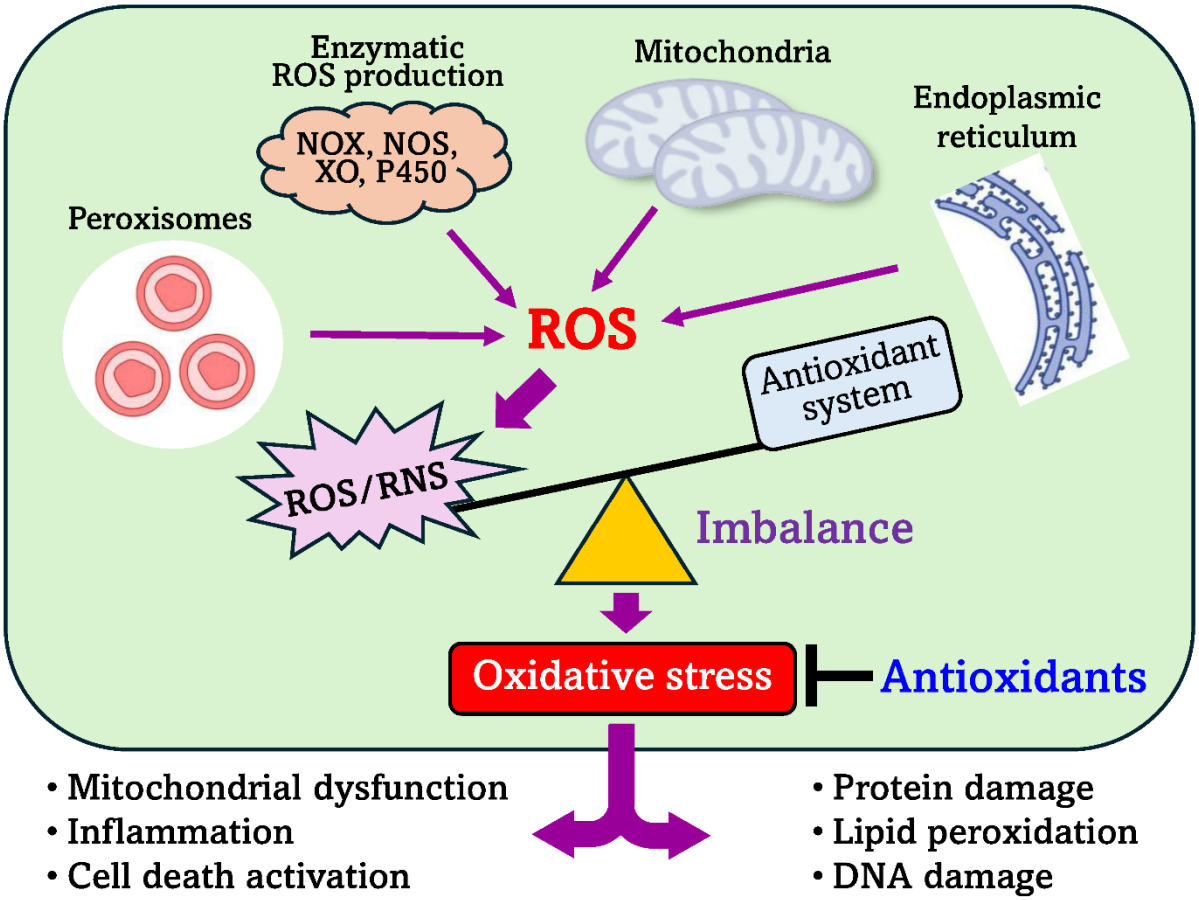
Pulmonary fibrosis constitutes a major group of progressive interstitial lung diseases, and oxidative stress plays a central role in its pathogenesis. Antioxidant genes help maintain cellular redox homeostasis by encoding enzymes that neutralize reactive oxygen species (ROS). In this review, the regulation of antioxidant genes in the context of pulmonary fibrosis and the functions of the related genes are presented based on current literature.

Keywords: Pulmonary fibrosis, Nrf2, antioxidant genes, oxidative stress, HO-1, NQO1, oxidative stress response, antioxidant enzymes, idiopathic pulmonary fibrosis

GİRİŞ

Pulmoner fibroz, akciğer parankiminde ilerleyici fibroblast aktivasyonu ve aşırı ekstrasellüler matriks (ECM) birikimi ile karakterize kronik bir hastalıktır. Patogenezinde oksidatif stres, inflamasyon ve epitel-mezenkimal geçiş (EMT) gibi süreçler önemli rol oynamaktadır (Kinnula ve ark., 2005; Makena ve ark., 2023; Luo ve ark., 2024). Özellikle reaktif oksijen türlerinin (ROS) aşırı üretimi, epitel hücrelerinde hasara, fibroblast proliferasyonuna ve fibrotik yanıtın artmasına neden olur. Bu süreçlerin kontrolünde antioksidan savunma sistemleri ve bu sistemleri düzenleyen genler kritik öneme sahiptir. Akciğer, oksidanlara karşı oldukça gelişmiş bir savunma mekanizmasına sahiptir. Bu mekanizma; glutatyon, vitaminler, ürik asit gibi küçük moleküllü antioksidanlar, metal bağlayıcı proteinler (transferrin, laktoferrin, metallotiyonin) ve antioksidan enzimlerden oluşur. Hücre içi ve dışı düzeyde süperoksit ve hidrojen peroksit gibi reaktif türlerin detoksifikasyonu; glutatyon ilişkili enzimler, katalaz, glutatyon-S-transferazlar ve tioredoksin-peroksiredoksin sistemi gibi enzimatik yollarla sağlanır. Bu enzimler bronşiyal ve alveolar epitel hücreleri ile alveolar makrofajlarda yoğun olarak bulunur. Ancak, oksidatif yanıtın zayıflaması veya bu enzimlerin inaktivasyonu redoks dengesini bozarak pulmoner fibrozisin ilerlemesine katkıda bulunabilir (Paliogiannis ve ark., 2018). Artan kanıtlar, idiopatik pulmoner fibroz (İPF) patogenezinde oksidatif stresin belirleyici bir faktör olduğunu göstermektedir. Oksidatif stres; oksidan üretimi ile antioksidan savunma arasındaki dengenin oksidanlar lehine bozulması sonucu ortaya çıkar ve hücresel fonksiyon bozukluğu ile doku hasarına yol açar. Akciğer, yüksek oksijen

gerilimlerine maruz kalması nedeniyle bu strese karşı özellikle hassastır (Fois ve ark., 2020). Bu nedenle, antioksidan genlerin ekspresyonunun düzenlenmesi, oksidatif stresin dengelenmesi ve fibrotik süreçlerin yavaşlatılması açısından büyük önem taşımaktadır. Oksidatif stresin bu süreçlerdeki merkezi rolü, çeşitli patojenik mekanizmalar üzerinden açıklanabilir (Şekil 1).



Şekil 1'de, oksidatif stresin tetiklediği bu patojenik mekanizmalar şematik olarak gösterilmektedir.

Oksidatif stres, İPF'nin patogenezinde kritik bir rol üstlenmektedir. Bu durum birkaç temel mekanizma ile açıklanabilir:
a) Sitokin ve büyüme faktörü üretimini artırarak inflamasyonu teşvik eder.
b) Hücre dışı matriksin parçalanmasını ve miyofibroblast farklılaşmasının artmasını tetikleyerek fibrogenez ve epitelizasyona yol açar.
c) DNA hasarı ve p53 aktivasyonunun bir sonucu olarak, ROS hava yolu epitel hücrelerinde apoptozu indükler ve alveolar epitelin yenilenme kapasitesini bozar.

Bu patolojik değişiklikler, pulmoner fibrozisin ilerlemesine önemli ölçüde katkıda bulunmaktadır (Fois et al., 2020).

ANTİOKSİDAN GENLERİN TANIMI ve ÖNEMİ

Antioksidan genler, oksidatif stresin düzenlenmesinde kilit rol oynar ve bu nedenle pulmoner fibrozis patogenezinde kritik öneme sahiptir. Hücresel sağlığın korunması için reaktif oksijen türleri (ROS) üretimi ile antioksidan savunma mekanizmaları arasındaki dengenin sağlanması kritik öneme sahiptir. Hücreler, sitoplazma ve organellerde ROS'u nötralize ederek redoks homeostazını koruyan enzimatik ve enzimatik olmayan bileşenlerden oluşan güçlü bir antioksidan savunma sistemine sahiptir. Enzimatik antioksidanlar arasında süperoksit dismutaz (SOD), katalaz (CAT), glutatyon peroksidaz (GPx) ve glutatyon redüktaz yer alır. Enzimatik olmayan antioksidanlar ise glutatyon (GSH), ubikinon (koenzim Q10), C ve E vitaminleri, alfa-lipoik asit ve tioredoksinlerdir. Bu bileşenler, aşırı ROS birikimini önleyerek oksidatif stresi azaltır ve hücresel redoks homeostazının korunmasına katkıda bulunur. ROS düzeyinin antioksidan kapasitenin üzerine çıkması, oksidatif hasara yol açarak çeşitli patolojik süreçleri başlatabilir.

Şekil 2: Hücre içi ROS kaynakları ve oksidatif stresin sonuçları. Ayrıntılar için metne bakınız. **Kısaltmalar:** NOS, nitrik oksit sentaz; NOX, NADPH oksidazlar; XO, ksantin oksidaz.

Son otuz yılda yapılan çalışmalar, ROS'un yalnızca zararlı bir yan ürün olmadığını, aynı zamanda hücre içi sinyal iletiminde önemli roller üstlendiğini ortaya koymuştur. ROS, bakterisidal aktivite, metabolik reaksiyonlar ve gen ekspresyonu gibi kritik hücresel işlevleri düzenler. Son on yılda artan kanıtlar, ROS'un fizyolojik adaptasyon ve savunma yanıtlarında da görev aldığını göstermektedir. Bu durum, antioksidanların aşırı ROS'u ortadan kaldırırken bazı fizyolojik süreçleri de etkileyebileceğini düşündürmektedir. Antioksidanların faydası, genellikle ROS seviyelerinde veya oksidasyon ürünlerinde azalma yoluyla hücre ve dokularda oksidatif hasarı önlemelerinden kaynaklanır (Kozlov ve ark., 2024). ROS, hem endojen (mitokondri, NADPH oksidazlar) hem de eksojen (radyasyon, bazı ilaçlar, gıdalar, sigara dumanı, çevresel kirlilik) kaynaklardan üretilir. Bu kaynaklardan artan ROS/RNS üretimi, oksidatif stres olarak bilinen zararlı duruma neden olur. Pek çok kronik hastalığın kökeninde farklı faktörler yer alsa da, bu hastalıklar için ortak payda

oksidatif strestir. Oksidatif stresin zararlı etkilerinin azaltılmasında antioksidan enzimler (SOD, katalaz, GPx) ve düşük molekül ağırlıklı antioksidanlar (C ve E vitaminleri, flavonoidler, karotenoidler, melatonin, ergotionin vb.) birlikte görev yapar. İnsan vücudundaki oksijenin yaklaşık %4–5'i biyolojik indirgeyiciler tarafından ROS'a dönüştürülür. Özellikle yüksek oksijen basıncına maruz kalan hücreler sürekli ROS saldırısı altındadır ve bu durum güçlü bir antioksidan savunma gerektirir **(Jomova ve ark., 2023)**

Antioksidanlar İki Ana Grupta Sınıflandırılır:

Antioksidan enzimler: ROS'u daha stabil ve daha az zararlı bileşiklere dönüştüren protein/metaloproteinlerdir. SOD, katalaz ve GPx en kritik olanlarıdır.

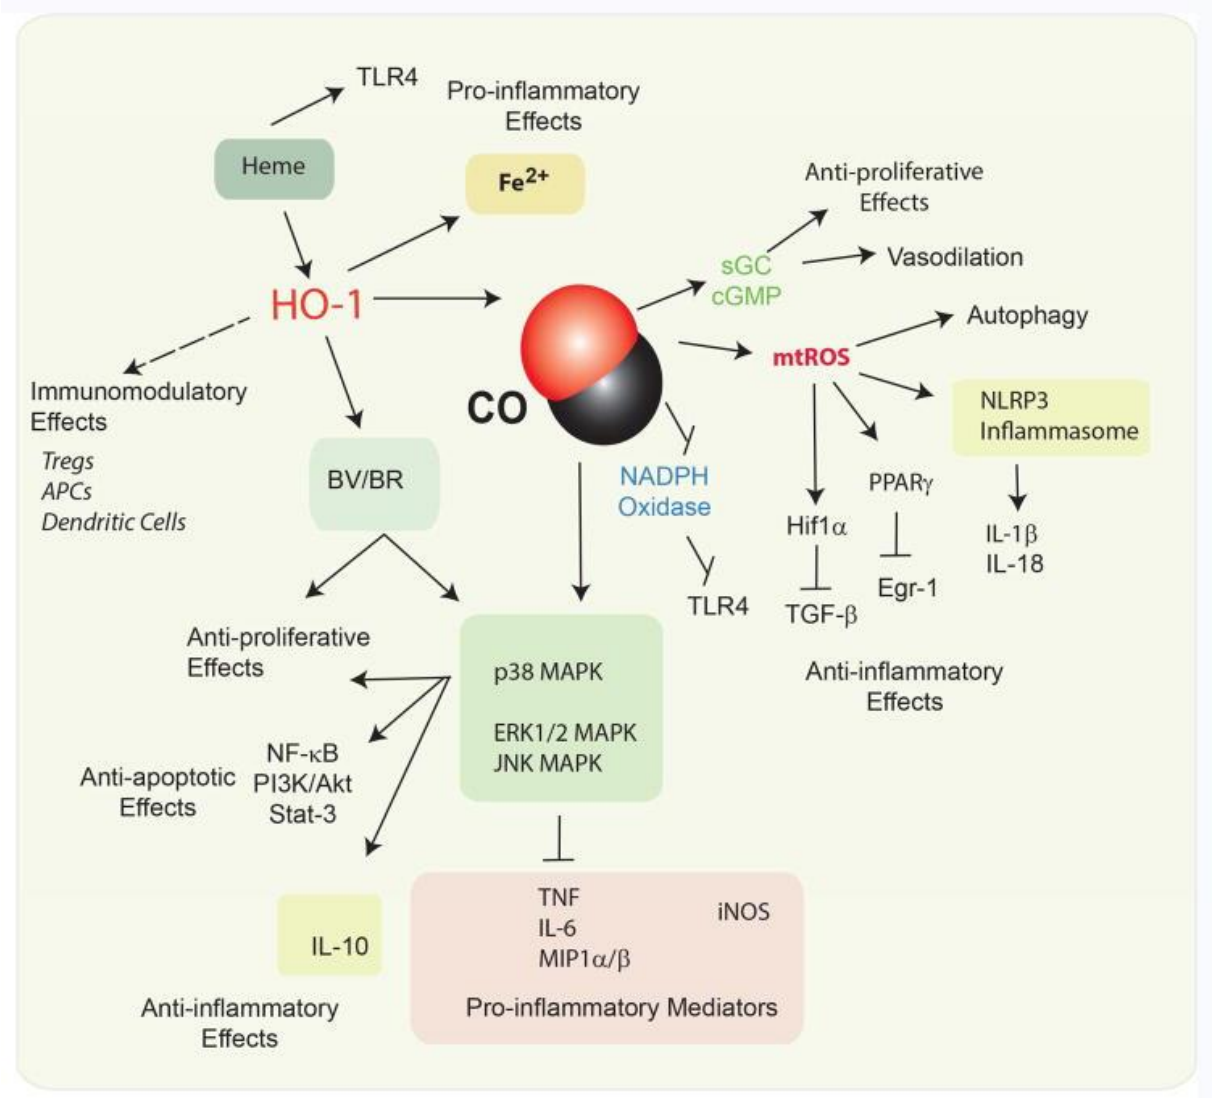
Düşük molekül ağırlıklı antioksidanlar: C vitamini, E vitamini, karotenoidler, flavonoidler ve glutatyon gibi bileşenleri içerir (Jomova ve ark., 2023).

ROS üretiminin artmasıyla NF-κB ve AP-1 gibi transkripsiyon faktörleri aktive olur. Bu faktörler, TNF-α ve IL-6, IL-8 gibi proinflamatuar sitokinlerin transkripsiyonunu artırarak nötrofil ve makrofajları aktive eder; böylece inflamatuar yanıt oluşur (Drost ve ark., 2005; Federico ve ark., 2007). Lökositler patojenleri yok etmek için süperoksit, hidroksil radikali ve peroksinitrit gibi ROS üretir. Ancak ROS'un döngüsel ve aşırı üretimi kronik inflamasyonu teşvik ederek DNA hasarına, mutasyonlara ve tamir mekanizmalarının bozulmasına yol açabilir. Bu nedenle, antioksidan genler, oksidatif stresin yol açtığı hücresel hasarı sınırlayarak pulmoner fibrozis gibi kronik hastalıkların gelişiminde merkezi bir rol oynamaktadır.

PULMONER FİBROSİZDE ÖNE ÇIKAN ANTİOKSİDAN GENLER VE DÜZENLEYİCİLERİ

Antioksidan Genlerin Ana Düzenleyicisi:

NFE2L2 (Nrf2)



Nükleer faktör eritroid 2 ile ilişkili faktör 2 (Nrf2), oksidatif stres yanıtının ana düzenleyicisi ve kritik bir transkripsiyon faktörüdür. Antioksidan yanıt elemanı (ARE) içeren genlerin ekspresyonunu düzenleyerek glutatyon S-transferaz (GST), NAD(P)H kinon oksidoredüktaz 1 (NQO1), heme oksijenaz-1 (HO-1), GCLC ve GCLM gibi antioksidan enzimlerin sentezini artırır ve hücreleri oksidatif hasara karşı korur **(Vézina ve Cantin, 2018; Ma, 2013).** Nrf2, CNC-bZIP ailesine ait bir transkripsiyon faktörüdür ve bronşiyal ile alveoler epitel hücreleri, alveoler makrofajlar ve hücre dışı ortamda lokalize edilen birçok antioksidan pulmoner proteinin ekspresyonunu kontrol eder. Normal koşullarda Nrf2, Keap1 proteini tarafından sitoplazmada tutulur. Oksidatif stres varlığında Keap1 modifiye olur, Nrf2 serbest kalarak çekirdeğe taşınır ve hedef genleri aktive eder. Bu mekanizma, hücreleri oksidan yüküne karşı koruyan kritik bir adaptif yanıt oluşturur. İPF modellerinde Nrf2'nin önemi, eksikliğinin bleomisin kaynaklı pulmoner fibrozu önemli ölçüde artırdığı deneylerle gösterilmiştir. Nrf2 eksikliği, bleomisin ile indüklenen pulmoner fibrozis modellerinde hayatta kalma oranını düşürür, oksidatif stres göstergelerini artırır ve fibrotik yanıtı şiddetlendirir (Raghu ve ark., 2011; Cho ve ark., 2002). Nrf2 agonistleri, antioksidan gen ekspresyonunu artırarak oksidatif stres kaynaklı hasarın azaltılmasında ve fibrotik hastalıkların önlenmesinde potansiyel terapötik hedef olarak değerlendirilmektedir. Ayrıca Nrf2, faz 2 detoksifiye edici enzimlerin ve çeşitli antioksidan enzimlerin ARE aracılı transkripsiyonel aktivasyonu yoluyla karsinogenez ve oksidatif strese karşı hücresel savunmada önemli rol oynar. Özetle, Nrf2, pulmoner fibroziste oksidatif stresin yol açtığı hücresel hasarı sınırlayan ve antioksidan gen ekspresyonunu düzenleyen merkezi bir transkripsiyon faktörüdür.

PULMONER FİBROZDA ÖNE ÇIKAN ANTİOKSİDAN GENLER

HMOX1 (HO-1)

HMOX1, heme oksijenaz-1 (HO-1) enzimini kodlar ve heme'in parçalanmasıyla biliverdin, serbest demir ve karbon monoksit (CO) üretir. Bu ürünler, antioksidan ve antiinflamatuvar etki gösterir ve genellikle Nrf2 tarafından indüklenir (Ryter ve Choi, 2016). Heme oksijenaz-1 (HO-1), heme metabolizmasında kritik bir basamak olan oksidatif yıkımı katalize ederek biliverdin ve karbon monoksit gibi biyolojik olarak aktif ürünlerin oluşumunu sağlar; bu ürünler antioksidan ve antiinflamatuvar işlevlere sahiptir. Dokuda HO-1

ekspresyonunun artışı, artmış inflamasyon veya oksidatif stres ile ilişkilidir ve akut akciğer hasarı (ALI) ile iskemi/reperfüzyon (I/R) modellerinde gözlenmiştir. HO-1'in sitoprotektif etkileri, heme'nin prooksidan özellik göstermesinin önlenmesi ve biyolojik olarak aktif ürünlerin oluşumu ile açıklanabilir. HO-1 ürünleri, farmakolojik uygulamalarda da inflamasyonu azaltarak doku koruyucu etkiler gösterir. HO-1, antijen sunan hücreler, dendritik hücreler ve düzenleyici T hücrelerinin fonksiyonlarını modüle ederek immün yanıtı etkileyebilir. Heme pro-inflamatuar etki gösterirken, HO-1 ürünleri inflamasyonu baskılar. CO, apoptotik, proliferatif ve inflamatuar hücresel programları düzenler; pro-inflamatuar sitokinlerin (IL-1β, IL-6, TNFα, Mip1α/β) üretimini azaltır ve anti-inflamatuar sitokin IL-10'u artırır. Bu etkiler, özellikle p38 MAPK yolaklarındaki değişikliklerle ilişkilidir. CO ayrıca mitokondriyal ROS üretimini uyararak otofajiyi teşvik edebilir, HIF-1α'yı aktive edebilir ve pro-inflamatuar transkripsiyon faktörü Egr1'i baskılayabilir. Son kanıtlar, CO'nun NLRP3 inflamatuar aktivasyonunu ve IL-1β ile IL-18 üretimini modüle edebileceğini göstermektedir. HO-1 reaksiyonunun bir diğer ürünü olan bilirubin (BR) anti-enflamatuar ve anti-proliferatif etkilere sahiptir. Bu mekanizmalar, HO-1'in pulmoner fibrozis ve oksidatif stres kaynaklı akciğer hasarında koruyucu rolünü vurgular (Ryter ve Choi, 2016). In vitro çalışmalar, epitel hücreleri, fibroblastlar, makrofajlar ve düz kas hücrelerinde hiperoksi sonrası HO-1 gen ekspresyonunun arttığını göstermiştir. Bu artışın nedeni, mRNA stabilitesinden ziyade HO-1 gen transkripsiyonunun yükselmesidir (Lee ve ark., 1996). Özetle, HO-1, reaksiyon ürünleri aracılığıyla oksidatif stres ve inflamasyonun yol açtığı akciğer hasarını sınırlayan merkezi bir koruyucu mekanizmadır.

NQO1

NQO1, NAD(P)H kinon redüktaz 1 enzimini kodlar ve kinonları toksik serbest radikallere dönüşmeden indirger. Bu mekanizma, oksidatif stresin zararlı yan ürünlerini detoksifiye ederek akciğer dokusunun korunmasına katkıda bulunur (Ma, 2013). NQO1, ARE-güdümlü antioksidan genler arasında öne çıkar ve hücreleri oksidatif stres ile elektrofillerin toksisitesine karşı korur. Pulmoner fibroziste, akciğer epitel ve fibroblastları artan ROS'a maruz kaldığında Nrf2 aktivasyonu tetiklenir ve NQO1 ekspresyonu yükselir. Bu artış, lipid peroksidasyonu ve DNA hasarını azaltarak fibroblast aktivasyonunu sınırlar **(Ma, 2013; Ryter ve Choi, 2016).** Sonuç olarak, NQO1, pulmoner fibroziste adaptif antioksidan yanıtın kritik bir bileşeni olarak işlev görür.

SOD1/SOD2

Süperoksit dismutazlar (SOD), süperoksit radikallerini hidrojen peroksite dönüştürerek hücreyi oksidatif hasardan korur. SOD2 özellikle mitokondride lokalizedir ve mitokondri kaynaklı ROS'un birikimini azaltır. Pulmoner fibrozda, SOD2 ekspresyonunun azalması mitokondriyal disfonksiyonla ilişkilendirilmiştir (Wang ve ark., 2025). İdiyopatik pulmoner fibroziste (İPF), SOD2 genellikle düşük ifade edilirken, SOD1'in biraz artmış olabileceği yönünde bulgular mevcuttur. Veith (2019), SOD1'in İPF'de arttığını ve SOD1 geninin yokluğunda farelerin asbest maruziyetine karşı daha az oksidatif stres geliştirdiğini bildirmiştir. Epigenetik baskılama yoluyla SOD2 ekspresyonunun azalması, mitokondriyal ROS birikimini artırarak pulmoner fibrozisi şiddetlendirebilir. Bu mekanizma, mitokondriyal oksidatif stresin artmasına ve fibrozisin ilerlemesine katkıda bulunmaktadır (Wang ve ark.,2025). Antioksidan tedavilerin etkinliği üzerine yapılan bir meta-analiz, tek başına veya kombinasyon halinde SOD kullanımını değerlendirmiştir. (Kandhare ve ark.,2016) tarafından gerçekleştirilen çalışmada, lesitinleştirilmiş SOD dahil olmak üzere antioksidan monoterapinin DLCO (karbon monoksitin yayılma kapasitesi) üzerinde belirgin bir etkisi olmadığı, ancak kombine antioksidan tedavinin hayati kapasite ve DLCO'da monoterapiden daha etkili olabileceği gösterilmiştir. Bununla birlikte, bu faydalar ölüm oranı veya advers olaylarda anlamlı farklılık yaratmamıştır (Fois ve ark., 2018). Özetle, SOD1 ve SOD2, süperoksit radikallerini detoksifiye ederek pulmoner fibroziste oksidatif stresin yol açtığı hücresel hasarı sınırlayan ve mitokondriyal fonksiyonları koruyan temel antioksidan enzimlerdir. Bu genlerin ekspresyon düzeyleri ve düzenlenmesi, fibrotik sürecin şiddetini doğrudan etkileyebilir.

CAT(KATALAZ)

Hidrojen peroksiti su ve oksijene dönüştürür ve SOD aktivitesinin ürettiği H_2O_2'yi detoksifiye eder. Katalaz, tercihen bronşiolar ve alveolar epitel hücrelerinde eksprese edilir ve normal akciğerlerde endojen bir antioksidan enzim olarak işlev görür. Odajima ve arkadaşlarının (2010) çalışmasında, pulmoner fibrozisli insan akciğerlerinde katalaz ekspresyonunun ve aktivitesinin azaldığı gösterilmiştir. Bu azalma, bronşiolar epitel hücrelerinde ve fibrotik alanlarda anormal re-epitelizasyonla ilişkilendirilmiştir. Katalaz enzimi, hücre içi hidrojen peroksiti zararsız bileşenler olan su ve oksijene indirger, böylece oksidatif stresin neden olduğu potansiyel doku hasarını sınırlamada kritik bir görev üstlenir. Pulmoner fibrozda katalazın yetersiz aktivitesi hastalık ilerlemesini artırabilir (Odajima ve ark., 2010). Katalaz, hücrelerdeki hidrojen peroksiti su ve oksijene dönüştüren bir enzimdir ve bu özelliğiyle hücreyi oksidatif stresten korur. Süperoksit dismutaz (SOD), süperoksit radikalini H_2O_2'ye dönüştürürken, katalaz bu H_2O_2'yi zararsız su ve oksijene çevirir. Bu iki enzim arasındaki işbirliği, hücredeki oksidatif dengenin korunmasında kritik bir rol oynar (Nandi ve ark., 2019). Shi ve arkadaşlarının (2013) çalışmasında, katalaz tedavisi uygulanan farelerde histolojik olarak azalmış fibrozis, bronkoalveoler lavaj (BAL) sıvısında azalmış kolajen seviyeleri ve azalmış inflamasyon gözlemlenmiştir. Bu bulgular, katalazın pulmoner fibrozisi azaltmada potansiyel bir terapötik ajan olarak rol oynayabileceğini göstermektedir (Shi ve ark., 2013). Özetle, katalaz, süperoksit dismutaz tarafından üretilen hidrojen peroksiti zararsız bileşenlere dönüştürerek hücreyi oksidatif stresten koruyan kritik bir enzimdir. Pulmoner fibroziste katalazın yetersiz aktivitesi, oksidatif hasarın artmasına ve hastalık progresyonuna katkıda bulunabilir; bu nedenle katalaz hem patogenez anlayışında hem de potansiyel terapötik stratejilerde merkezi bir rol oynar.

GCLC/GCLM

GCLC ve GCLM, glutatyon sentezinin hız kısıtlayıcı enzim alt birimleridir. Nrf2 aktivasyonu ile ekspresyonları artar ve hücre içi glutatyon havuzunun yenilenmesini sağlar, böylece oksidatif stresin yol açtığı hasara karşı kritik bir savunma mekanizması oluşturur. Pulmoner fibroz modeli olarak kullanılan fare akciğerinde, Transforming Growth Factor β1 (TGF-β1), glutatyon (GSH) sentezinde hız sınırlayıcı olan GCLC (katalitik) ve GCLM (modülatör) alt birimlerinin mRNA ve protein düzeylerini baskılayarak GCL aktivitesini düşürmüş; bu durum akciğer GSH seviyesinde azalmaya yol açmıştır (Liu ve ark., 2012). Özetle, GCLC ve GCLM, glutatyon sentezini düzenleyerek hücre içi antioksidan kapasiteyi sürdüren kritik enzim alt birimleridir. Pulmoner fibroziste bu genlerin ekspresyonundaki azalma, GSH havuzunun tükenmesine ve oksidatif stres kaynaklı akciğer hasarının artmasına yol açarak hastalık progresyonunu destekler.

GPX1 (Glutatyon Peroksidaz 1)

GPx enzimleri, zararlı H_2O_2'nin yanı sıra çeşitli hidroperoksitlerin (DNA peroksitleri ve lipid peroksitler gibi) su ve alkollere indirgenmesini katalizler. Bu reaksiyonda GSH'yi indirgeyici olarak kullanır ve biyomembranları ile hücresel bileşenleri oksidatif strese karşı korur. GPX1, hem selenyuma bağımlı hem de bağımsız bir antioksidan enzim ailesinin üyesidir (Brigelius-Flohé, 2006). GPX1, peroksinitrite maruz kalan insan lökositlerinde NFκB/AP-1 aktivasyonunu ve proinflamatuar gen ekspresyonunu baskılar. GPX1 ekspresyonunun azalması artmış oksidatif stres ve inflamasyonla ilişkilidir. Sigara dumanı gibi çevresel stres faktörleri GPX1 aktivitesini etkileyebilir ve terapötik hedef olarak incelenmektedir. Veriler, GPX1'in sigara dumanına bağlı akciğer iltihabını kontrol etmek için gerekli olduğunu ve in vivo olarak hedeflenmesinin terapötik fayda sağlayabileceğini göstermektedir. Ayrıca GPX1 eksikliği olan farelerin başlangıçta normal BALF hücre sayısına sahip olması (sigara dumanına maruz kalmadığında) GPX1'in koruyucu rolünü destekler (Vlahos ve Bozinovski, 2013).

TXN/TXNRD (Tioredoksin / Tioredoksin Redüktaz)

Tioredoksin redüktaz (TrxR), tioredoksin (Trx) ve NADPH'den oluşan Trx sistemi, canlı hücrelerdeki başlıca antioksidan sistemlerden biridir. Bu sistem, diğer antioksidan enzimlerin redoks durumunu düzenleyerek hücreleri oksidatif strese karşı korur (Arnér, 2020). TrxR/Trx'i hedefleyen organik bir selenyum bileşiği olan butaselen (BS), TrxR/Trx inhibitörüdür ve anti-tümör aktivitesinin yanı sıra NF-κB/TGF-β1/Smads sinyalini inhibe ederek pulmoner fibrozu baskılar. Butaselenin hem in vitro hem in vivo çalışmalarda pulmoner fibrozisi azalttığı ve pirfenidona benzer etkinlik gösterdiği bildirilmiştir (Chen ve ark., 2023). TXN/TXNRD sistemi, özellikle alveolar epitel hücrelerinde kritik rol oynar ve oksidatif hasara karşı koruma sağlar (Chen ve ark., 2023).

PRDX (Peroksiredoksin)

Peroksiredoksin ailesinin bir üyesi olan PRDX1, ROS seviyelerinin düzenlenmesine ve diğer fizyolojik süreçlere katılır. PRDX1 yıkımı, akciğer epitel hücrelerinde ROS'u artırarak PI3K/Akt ve JNK/Smad yolları üzerinden EMT'yi teşvik eder. PRDX1 nakavtı, primer fibroblastlarda TGF-β sekresyonunu, ROS üretimini ve hücre göçünü artırır. Eksiklik, hücre proliferasyonu ve fibroz ilerlemesini hızlandırır. Bleomisin tedavisi PRDX1-nakavt farelerde daha şiddetli fibroz oluşturmuştur (Sun ve ark., 2023). PRDX ailesi, H_2O_2 ve organik peroksitleri indirgerken tioredoksin sistemiyle çalışarak redoks homeostazını sağlar. PRDX düzeylerindeki değişiklikler, fibroblast aktivasyonu ve inflamatuvar yanıtları etkiler. Aşırı oksidasyon PRDX'lerin fonksiyon kaybına yol açabilir. PRDX proteinlerine karşı gelişen otoantikorlar IPF hastalarında saptanmıştır ve bu proteinler terapötik hedef olarak değerlendirilmektedir (Elko ve ark., 2019).

G6PD (Glukoz-6-Fosfat Dehidrogenaz)

G6PD, pentoz fosfat yolunun hız sınırlayıcı enzimidir ve NADPH üretimi yoluyla redoks dengesinin korunmasında kritik rol oynar. NADPH, glutatyon sisteminin yeniden indirgenmesi için gereklidir. G6PD eksikliği, GSH/GSSG oranında azalma, akciğer dokusunda nitrasyon artışı ve proinflamatuar yolakların (PI3K, ERK1/2, AMPK) aktivasyonu ile ilişkilidir (Nicolás ve ark., 2018). Eksiklik, oksidatif stresin artmasına ve vasküler proliferasyona neden olur. Ayrıca hemoliz, metabolik yeniden programlama ve artmış ROS üretimi ile

pulmoner hipertansiyon ve fibrotik değişiklikler gelişebilir (Varghese ve ark., 2021). G6PD, NADPH üretimi ile glutatyon ve tioredoksin sistemlerini destekler. Hipoksiye bağlı damar yeniden yapılanması ve pulmoner hipertansiyon gelişiminde önemli bir rolü vardır (Varghese ve ark., 2021).

Pulmoner Fibrozda Öne Çıkan Antioksidan Genlerin Klinik Önemlerinini Özetleyecek Olursak

Pulmoner fibroziste oksidatif stresin dengelenmesinde birçok antioksidan gen kritik rol oynamaktadır. NFE2L2 (Nrf2), oksidatif stres yanıtının ana düzenleyicisidir ve HO-1, NQO1 gibi genleri aktive ederek savunma mekanizmalarını güçlendirir. HMOX1 (HO-1) heme yıkımını katalizlerken antiinflamatuvar etki gösterir. NQO1, kinonları toksik radikallere dönüşmeden indirger. SOD1 ve SOD2, süperoksit radikallerini H_2O_2'ye dönüştürerek oksidatif hasarı azaltır; katalaz ise H_2O_2'yi su ve oksijene çevirir. GCLC ve GCLM, glutatyon sentezinde görev alırken GPX1, H_2O_2 ve lipid peroksitleri indirger. TXN/TXNRD sistemi hücresel redoks dengesini korur; PRDX proteinleri peroksitlerin indirgenmesinde rol oynar. G6PD ise NADPH üretimiyle glutatyon sistemini destekler.

MATERYAL YÖNTEM

Bu derleme çalışma, literatür temelli bir derleme olarak hazırlanmıştır. PubMed, Scopus ve Web of Science veritabanları taranarak 2000–2025 yılları arasında yayımlanmış İngilizce ve Türkçe makaleler incelenmiştir. Tarama işlemlerinde "pulmonary fibrosis", "oxidative stress", "antioxidant genes", "Nrf2", "HO-1", "SOD", "GPX1" anahtar kelimeleri ve bunların kombinasyonları kullanılmıştır.

SONUÇ

Pulmoner fibrozis, oksidatif stresin ve inflamatuar yanıtın birbirini tetiklediği kompleks bir süreçtir. Bu süreçte Nrf2 proteini (NFE2L2 geni tarafından kodlanır) ve onun düzenlediği HO-1, NQO1, SOD, katalaz, GPX1, TXN/TXNRD, PRDX, GCLC/GCLM ve G6PD gibi genler, ROS ve RNS üretimini dengede tutarak hücresel hasarı sınırlayan temel koruyuculardır. Bu genler, epitel hücreleri, fibroblastlar ve alveolar makrofajları oksidatif strese karşı korurken inflamatuar yanıtın zararlı etkilerini azaltır. Son dönem çalışmalar, doğal ve farmakolojik ajanların bu genleri hedefleyerek oksidatif stresi ve fibrotik ilerlemeyi azaltabileceğini ortaya koymaktadır. Dolayısıyla, antioksidan genlerin düzenlenmesi, pulmoner fibrozis tedavisinde hem koruyucu hem de terapötik bir strateji olarak öne çıkmakta ve gelecekteki araştırmalar için umut vadetmektedir.

Özet

KBRN olayları, çok kısa bir zaman içinde kontrol edilemeyen sonuçlar doğurabildiği için hem müdahale ekiplerini hem de yöneticileri zorlayan olaylardır. Bu olaylarda hangi ajanın devrede olduğunu anlamak her zaman kolay değildir. Ekipler çoğu zaman ilk dakikalarda yalnızca ortamda bir terslik olduğunu hisseder ve bu his, müdahale kararlarını bir süre yönlendirir. Farklı ajan türlerinin kendine özgü yayılma şekilleri, tanı ve müdahale süreçlerini daha da zorlaştırır. Kimyasal tehditler genellikle hızlı belirtiler gösterirken biyolojik ajanlar çoğu zaman daha geç fark edilir. Radyolojik ve nükleer maruziyetlerde ise belirtiler gecikebilir ya da hiç belirgin olmayabilir. Bu belirsizlik, özellikle ilk müdahale ekipleri için önemli bir güçlük oluşturur. KBRN yönetiminde hazırlık çalışmaları teori ile pratik arasındaki en görünür farkı ortaya çıkarır. Teknik açıdan mükemmel görünen planlar sahada beklenmedik şekilde aksayabilir. Düzenli yapılan tatbikatlar, ekiplerin gerçek bir olayda hata yapma olasılığını belirgin şekilde düşürür; bu yüzden hazırlık sürecinin en pratik unsurlarından kabul edilir. Kurumlar arası koordinasyon da bu süreçte kritik bir rol oynar. Küçük bir iletişim boşluğu bile zincirleme gecikmelere yol açabilir ve bu durum müdahale kapasitesini belirgin şekilde düşürür. İlk müdahale ve dekontaminasyon uygulamaları, olayın daha geniş bir krize dönüşmesini engelleyen temel aşamalardır. Triyaj ise çok sayıda mağdur içeren olaylarda sağlık kaynaklarının doğru kullanılmasını sağlar. Su ve besin güvenliği, olay sonrası dönemde ikincil salgınların önlenmesi açısından hayati bir alanı temsil eder. Tüm bu süreçler, KBRN olaylarının yalnızca teknik bilgi değil, aynı zamanda güçlü bir organizasyon ve sürekli iletişim gerektirdiğini göstermektedir. Bu çalışma, KBRN kapsamındaki müdahale süreçlerini gözden geçirirken farklı disiplinlerin hangi aşamalarda katkı sağlayabileceğini de tartışmaktadır.

Disaster management and response coordination in CBRN Incidents: Current approaches and practical frameworks

Abstract

The first moments of a CBRN event rarely feel organized, and most responders describe them as a mix of confusion and instinctive reactions. People at the scene often notice unusual smells, sudden discomfort, or strange behavior in the environment long before anyone confirms a chemical or biological release. These early hints shape their decisions, even though no one fully trusts those impressions at the time. Different threat types behave in ways that challenge responders' expectations. Chemical agents may trigger visible symptoms quickly, sometimes too quickly for structured protocols to keep up. Biological threats, on the other hand, remain silent for hours or days, leaving teams unsure about when the real danger started. Radiological or nuclear exposures can be even more complicated, because physical signs may never appear. This mix of visible and invisible risks forces teams to act while still questioning what they are dealing with. Preparedness efforts try to narrow this uncertainty, yet real situations often expose gaps that training sessions never reveal. During drills, small timing issues look minor; during an actual emergency, the same issues can interrupt an entire operation. Coordination becomes fragile when information travels unevenly, and most delays begin with something as simple as a message that arrives a few minutes late. Initial actions—securing the area, assessing exposure, and
